Dr. F. J. O'DONNELL described a series of cases of an insidious type of pleural empyema, in which the classical symptoms were absent. This type might be suspected only from: (a) the failure to reemperate rapidly after the crisis of lobar pneumonia despite the subsidence of acute symptoms; (b) the early onset of facial pallor with cyanosis of the lips; (c) the constant increase of the pulse rate. The temperature chart might give no indication of the presence of empyema, but both debility and anaemia after pneumonia were always to be regarded as strong presumptive evidence of the condition. This type of empyema might develop slowly during convalescence, and physical signs the early stages. The diagnosis of pus in the upper thorax might be particularly difficult, as in the case of a boy of 9, who was believed to be suffering from acute tuberculosis of the left upper lobe, but who eventually developed an abscess over the precordium, which ruptured and discharged completely at this site. The prognosis of pneumococcal empyema was good if diagnosed reasonably early and efficiently treated, but rapid pneumococcal septicaemia might occasionally produce a fatal issue. In treatment the series of cases supported the conclusion that patients acutely ill, or in a low condition, withstood operative treatment badly, and that in such patients aspiration was preferable until the critical period had passed.

Dr. G. E. NESBITT said that Dr. O'Donnell had not referred to the use of x-rays in diagnosis, which he had personally found helpful in all varieties of chest cases. He had recently seen a case of liver abscess, similar to the one described by Dr. O'Donnell, in which he had found what he took to be typical signs of empyema at the base of the right lung; on putting in a needle he had only found a little blood-stained fluid. By an x-ray examination it was discovered that the trouble was a liver abscess. An operation was performed, and a large quantity of pus came away; the patient did well for a time, but another abscess developed in the left lung. This also was drained, and the patient recovered.

Dr. J. SREANES referred to the abnormal sweats which occurred in patients who had suffered from pneumonia and recovered. He had seen a good many cases of liver abscess, and said that even in cases of tropical abscess a little fluid was obtained, and there were usually also crepitations present. Out of eleven cases of this condition which he had seen he had only found cysts in one case. He had recently seen a youth, aged 19, who had become suddenly ill; the abdomen was rigid. There was no previous history of illness. A needle was inserted, and a good deal of fluid came away. It was decided that it was a case of empyema and an operation was performed, but empyema was not found. The boy died, and at the necropsy perforation was found, the fluid having apparently come from the abdomen. He referred to the difficulty of cases of double empyema, and agreed with Dr. Nesbitt that x-rays in these cases were a valuable aid to diagnosis.

Dr. A. R. PARSONS had recently had a case of unresolved pneumonia, somewhat similar to the one described by Dr. O'Donnell. The patient, a man, came to the crisis, and his temperature rose afterwards, suggesting empyema. A radiologist was not certain whether fluid was present, so Dr. Parsons explored, with negative results. He then watched the case, and the condition gradually cleared up, but not for about five or six weeks. He drew attention to the importance of getting the surgeon to define the position of the pus after it had been found by the physician in cases of empyema, before any operation took place, owing to the difficulty in some cases of finding pus at the operation. He had seen a girl, aged 16, who on admission had a rash over her body; he could not determine whether there was pus or fluid present. No decision was obtained by an x-ray examination, so he explored, and withdrew about 1 c.cm. of pus, which was found to be purely streptococcal. He could not find any primary cause; although the girl was never drained she gradually improved and finally recovered.

Dr. D. J. CANNON was convinced that in cases of empyema, whether the infection was pneumococcal or streptococcal, aspiration alone would not cure the patient. On the other hand, if a rib was taken out at once the patient would probably die. The pus should always be examined bacteriologically; if it proved to be pneumococcal an operation should be performed at once, but if streptococcal it was wiser to temporize. The essential thing in the surgical treatment of this condition was efficient drainage; for this it was necessary to resect the rib and explore the cavity before putting in a drainage tube. He personally did not think it mattered whether open or closed drainage was used.

Dr. ELLA WEBB believed that x rays were the only certain aid in looking for empyema: the diagnosis between a tuberculous condition and an empyema was often difficult. She had seen a child, who had recently suffered from pleurisy, or what was said to be pleurisy. The child was very badly nourished, the parents were very poor, and the general appearance suggested tuberculosis. The occurrence of sweats with the history made the case very puzzling. She frequently saw similar cases: in some of them empyema was found, but other patients steadily grew worse, and at the autopsy generalized tuberculosis was found.

Dr. R. H. MICKS referred to a rare case in which the patient had measles and also typical empyema; on two occasions a diffuse growth of influenza bacilli was obtained. The patient was operated on; before it there was no fever, but after it the temperature rose.

Dr. L. ABRAHAMSON said he always had a vaccine prepared in cases of empyema, lest the opening should not close satisfactorily after operation, as in these circumstances he had found vaccines helpful. He drew attention to the danger of putting a needle into a case of abscess of the lung unless an operation was done very shortly afterwards. He mentioned a case in which a man was operated on, and it was found that the muscles of the chest wall were infiltrated with pus; gas bubbles escaped, and the patient afterwards died, probably of exhaustion. He had seen another case, in which, the x-ray examination being rather indefinite, an operation was performed for a subphrenic abscess, and an enormous quantity of pus came from the liver.

Dr. W. G. HARVEY did not think it was always difficult to get the needle into the pus, but in all cases where he suspected empyema he had a glass slide ready and blew any needle contents on to the slide for microscopical examination. By this means he had often found pus where he would not otherwise have done so. X rays were usually very useful, but in some cases even they failed. About a year ago he had had a case of a large empyema which was operated on; after the operation it ran a very unsatisfactory course, and he thought there must be some pus present. The patient was examined with x rays, but there was nothing abnormal seen. After the patient had returned home he coughed up about an ounce of pus.

Dr. V. M. SYNER said that as loud breathing was frequently found in cases of empyema in children as in cases of consolidation. In children empyema was often primary, and not preceded, as in adults, by pneumonia.

The PRESIDENT referred to leucocytosis as an aid to diagnosis in cases of empyema. He also had found clear fluid in the pleura in a case of abscess of the liver. He thought the case was one of empyema, and persuaded the patient to be operated on, but before the operation was done perforation into the lung occurred and the patient died of acute pneumothorax. He had recently had two cases in which pneumonia in the lower lobe of the right lung had failed to resolve until after two months, when all the physical signs disappeared.

### DEEP X-RAY THERAPY.

A MEETING of the Section of Pathology of the Royal Academy of Medicine in Ireland was held on February 20th, the President, Professor J. T. WIGHAM, in the chair.

Dr. L. CASSIDY read a report of deep x-ray therapy as practised by himself and Dr. Stumpf at the Coombe Hospital for nine months.

Dr. Cassidy stated that selected cases could be clinically cured, but cases which were surgically inoperable and had

been sent for this treatment as a last resort were usually disappointing, only a very small percentage (15 to 20) of cures resulting. Gynaecology provided the most successful field of operation for deep x-ray therapy, and next in order came sarcomata. In post-operative cases, when properly treated, good results were obtained; 8 cases had been treated. In 8 cases of abdominal and general tuberculosis 2 patients had died after the first sitting, but they had had a poor prognosis from the start; 3 patients were cured. In general deep therapy x rays were not so efficacious as in gynaecology, but many inoperable cases could be cured, or at least benefited, by the treatment. Out of 10 patients with cancer of the oesophagus 5 had died and 3 remained alive, with satisfactory results. In one case a growth was present 12 inches from the teeth; a snipping from the growth showed it to be a squamous cancer. Under treatment the discomfort disappeared, the weight improved, and a radiogram showed the condition to be almost normal. In cancer of the stomach the prognosis was worst, but cancer of the rectum was more favourable. Many cases showed improvement as regards pain, and there was permanent healing in a small percentage. Of cancer of the face 3 cases were treated; one canceroid of the nose was cured, one epithelioma reacted to one radiation, and one remained under treatment. Good results were obtained in cancer of the upper jaw: 3 patients were treated; the first two had finished treatment and no tumour was now visible. Treatment was given to 4 patients, with cancer of the lip, tongue, and mouth; glandular metastases were present in all. Improvement was obtained in all the cases. No success whatever followed treatment of 13 cases of cancer of the larynx, the difficulty being that the great sensitiveness of the larynx to the rays led to induration. In 6 cases of cancer of the pharynx only temporary improvement was obtained. One patient with cancer of the thyroid showed improvement, the tumour apparently becoming cystic. Many cases of sarcoma reacted favourably. Sometimes the primary tumour disappeared only to be followed by the appearance of metastases later. Lymphosarcomata reacted most favourably. In 4 cases of mediastinal tumour treated the results were very good, but bone sarcomata did not show any improvement. One case of laryngeal tuberculosis showed partial improvement, and treated cases of tuberculous glands in the neck were almost completely cured. A case of Basedow's disease showed some improvement after treatment.

The PRESIDENT considered that a great advance had been made in the treatment of malignant disease, even if it could only be said that by deep x-ray treatment the patients had been freed from pain for a few months, as had been achieved in some cases by Dr. Cassidy. Some of the patients had died soon after the treatment, and he wondered if this was merely a coincidence or had some connexion with the treatment. He referred to the difficulty of treating very advanced inoperable cases, and asked if squamous-celled carcinoma was more amenable to treatment than columnar-celled carcinoma.

Dr. W. STEVENSON referred to the number of hopeless cases in which some kind of radiation treatment was alone possible. All these patients must eventually die from cancer, since very often before they commenced radiation treatment the disease had spread over the system; all that could then be expected from treatment was that it would relieve the part of the body where the primary growth had started. He had found that by radium treatment he could prolong the life of patients, relieve their pain, and make them more comfortable; but it was a very different matter to cure them. There were many difficulties in radium treatment. Patients too often failed to come back for further treatment. He had been using radium in cases of tuberculous peritonitis for some time now with good results. He usually gave small doses of radium, and continued the treatment for a long time. He had treated one such patient for fifty-six days, and she ultimately recovered. In cancer of the breast radium treatment acted well; but he regarded this condition as a more or less superficial one which could be removed. He had treated a case of cancer of the bladder nearly three years previously; the patient had come in to see him recently, and was apparently quite

well. He felt that every patient should be given a chance of radiation treatment, because sometimes, even in cases which appeared hopeless, improvement was effected. The patients were made much more comfortable, and the mental relief also was very great; they realized that nothing else could be done for them and were very grateful for any alleviation of the pain. He had treated one case of cancer of the oesophagus; the patient had been much better for some time and free from pain; he had not died until nine months later. While he recognized that it was not a cure for cancer it was a means of combating the disease which would always be of use, and should never be cast aside. He thought that radium had some advantages over the treatment by deep therapy in that it could be given in very small doses and for a considerable length of time.

Mr. M. HAYES said that cases of cancer had been treated for many years by x rays before this method was adopted: some patients whom he had treated fourteen years ago were still alive. The newer method of deep x-ray therapy was introduced during the war, and he himself had only started to use it since last July, and therefore only in a few cases. There was at present a difference of opinion as to whether the treatment should be given without intermission, or whether it should be given with intervals between each treatment. There were points in the Erlangen technique which he could not agree with. He thought that the table of dosage suggested was likely to lead them astray; different forms of malignant disease responded differently to radiation, therefore in some cases large doses were required, while in others the dose had to be small. In cases of tuberculous peritonitis, unless the patient was in a condition to respond to the treatment, no good results would be obtained by deep x-ray treatment. He referred to a patient with cancer of the rectum, sent to him for treatment after the operation. He had received radium treatment, with the result that he was freed from symptoms and enabled to get back to work. He thought that without the operation the result would not have been so good. The results in carcinoma of the stomach were always bad, and always would be until some form of technique was invented which would save the suprarenals. In cancer of the parotid the results obtained by treatment by x rays were on the whole encouraging. Although by the use of deep x-ray therapy an advance had been made in the treatment of cancer, he did not think that it was going to solve the cancer problem. He thought it much safer to use radium for tumours in the region of the eyelid owing to the dangerous action of x rays in the rods and cones.

Dr. BETHEL SOLOMONS inquired as to the physical effects of deep x-ray therapy. Patients of his had refused to undergo a second application owing to the extreme discomfort suffered. He thought that the Government should be urged to allow post-mortem examinations in hospitals: the absence of these examinations retarded progress. With regard to cancer of the bladder, Paschikis had stated that radiation caused more suffering than the disease itself. An important economic problem arose in considering the question of deep x-ray therapy: should this expensive apparatus be constructed, or should the patients be treated with radium?

Dr. T. O. GRAHAM had seen no permanent good results in cases of cancer of the oesophagus, although he had had cases of his own treated by deep x rays, and also by radium; in some of them he had combined the treatments, but others had only had one or the other. In two cases the original growth apparently was cured by radium, but in a short time a second growth appeared lower down. He wondered if radium or deep x-ray treatment was likely to induce secondary growths by stimulating the cells to produce a growth if the treatment were not properly applied. He had had one case of cancer of the upper jaw in which there was proptosis and a very large secondary growth in the nose, which was reported to be carcinoma. The patient at that time seemed to be in a hopeless condition. He was blind in the proptosed eye, could not breathe through his nose, had very severe headaches, and was in great pain. This was about nine months ago; the patient was then treated by deep x rays, and when he

came back, three months later, for further treatment there was no visible growth. In another somewhat similar case, in which the growth had not involved the eye, improvement followed treatment, though the effect was not so extraordinary as in the previous case. This patient had had three treatments, and the swelling of the cheek and the roof of the mouth had decreased, but there was still a growth in the nose, which bled readily on the application of a cotton swab. It seemed that the time had now come when a radiotherapeutic institution was required in Dublin.

Dr. JOHN SPEARES referred to a case of mediastinal tumour. The patient had definite dullness under the sternum, extending up to the right upper lobe. After the first deep x-ray treatment the patient was extremely prostrated, he suffered from pyrexia, and said that he felt "knocked out." After a second treatment he was still more prostrated, again suffered from pyrexia, and died about ten days later. At the autopsy it was found that the sarcoma commenced in the mediastinal region and extended up to the right lobe; the lung was breaking down.

Dr. CASSIDY, replying, said that in tuberculous peritonitis the treatment lasted for one hour—half an hour for the back and half an hour for the front. Three applications were given, spreading over a period of a month or six weeks, and then the patient was considered as cured. Both patients with cancer of the parotid gland had died; but two with cancer of the lower jaw had been treated, and he had heard that both of them were completely well.

### ENCEPHALITIS LETHARGICA.

At a meeting of the Cardiff Medical Society held on February 10th, with Dr. E. E. BRIERLEY in the chair, Dr. ABEL EVANS read a paper on encephalitis lethargica.

Dr. Evans pointed out that the view, widely held, that this disease was first observed and established as a separate entity by von Economo of Vienna, who studied an outbreak in 1916, and published a full report in May, 1917, neglected the fact that a more extensive outbreak had occurred in France in 1915 and 1916, from which a series of forty cases was recorded by Cruchet, Moutier, and Calmette, in April, 1917. It was not described in England until 1918, when Professor A. J. Hall and Dr. Wilfred Harris published their first cases. Compulsory notification was instituted in this country as early as January, 1919, with the result that the statistical records of the epidemic issued by the Ministry of Health were singularly complete. The epidemic could not be said to have already spent its force. The mortality was high: it reached 48.3 per cent. in a series of 1,273 cases reported by the Ministry of Health. If, however, allowances were made for the very large number of mild cases which were not notified, this percentage would be much reduced. It was universally recognized that the infectivity of the disease was low, but there was abundant evidence that it was of long duration. The pathological changes seen by the naked eye were slight, amounting in most cases to a congestion of the superficial vessels of the central nervous system. On section, similar signs of congestion and minute haemorrhagic points were found in the substance of the brain and cord. The grey matter showed these changes more than the white, and they were seen with greater frequency in such situations as the basal ganglia and mid-brain. The microscopic changes were constant in well established cases, the most obvious being perivascular cuffing. The perivascular lymph spaces about veins of a small size were infiltrated by mononuclear lymphocytes and occasional plasma cells. Other less constant changes were degeneration of nerve cells and proliferation of astrocytes. No organism had yet been isolated, but the disease was now believed to be due to a filterable virus. This virus had been obtained from brain emulsions in fatal cases and from the washings of the nasopharynx; by inoculation the disease had been produced in animals. The cerebro-spinal fluid showed very few changes: it was clear and colourless; in the early stages the pressure might be somewhat raised, and the cell count might show from 50 to 100 lymphocytes per

cubic millimetre. The onset of the disease was as a rule gradual, but it might be dramatically sudden. The nervous symptoms were due to a general or to a local disturbance of the central nervous system which caused either an exaltation or a depression of function. Delirium and lethargy were typical general disturbances, while involuntary movements and paralysis were typical focal derangements. Focal symptoms might occur with little or no general disturbance. Gastro-intestinal symptoms occurred in the initial stages of the illness. The tongue was thickly coated, the breath very offensive, the fauces were infected, and obstinate constipation was present in a number of cases. In children, moral and temperamental changes were the most important residua. No line of treatment having curative or preventive value had yet been evolved.

Dr. IVOR J. DAVIES referred to a case of a man, aged 58, who died, after an illness of one month's duration, from a tumour of the lenticular nucleus, secondary to a growth (lymphosarcoma) at the root of the lung. The physical signs bore a close resemblance to those of encephalitis, lethargia, and were mainly of the general type (Walshe), with the negative signs of marked lethargy and Parkinsonian mask, as well as moderate ptosis, paresis of one external rectus muscle, and of the limbs of one side of the body. The ordinary signs of a cerebral tumour were absent.

### PREVENTION OF PUERPERAL DISEASE.

At a meeting of the London Association of the Medical Women's Federation held on February 10th, Miss M. CHADBECK in the chair, Miss FRANCES IVENS read a paper on the prevention of puerperal morbidity and mortality, with a view to indicating how far the immediate and remote morbidity after childbirth was preventable. Five years ago she had undertaken the supervision of the new maternity home in Liverpool, to which, since its opening in 1920, there had been 1,000 admissions. So far as possible Miss Ivens saw every case before admission, and made an examination, a specimen of any abnormal discharge being sent to the city bacteriologist for report. Cases of active syphilis or gonorrhoea were referred to a special institution, and cases of albuminuria, cardiac disease, or hyperemesis were admitted for ante-natal care. Patients requiring Caesarean section were transferred to the Stanley or Maternity Hospital. At this home, before any internal examination was made, the vulva was shaved and washed with lysol solution; in emergency cases tincture of iodine was also used. During labour all those concerned with the case wore sterilized overalls and boiled gloves. The matron or sister conducted all normal cases with the assistance of the tutor midwives, who were all trained nurses. Any perineal rupture was repaired at the earliest possible moment with silkworm gut. The wound was kept dry and was painted once daily with tincture of iodine. During the puerperium the vulva was swabbed over a douche-pan four-hourly during the day with lysol solution, and a large sterile pad was applied. The patient was encouraged to lie on her side for part of each day and to sleep in an exaggerated Sims's position which was not uncomfortable; anteversion of the uterus was thus encouraged. In cases of ruptured perineum micturition was performed in the hands and knees position so that the wound should not be soiled; catheterization was avoided. Of the 1,000 patients admitted, 206 were pre-maternity cases and 679 were maternity cases, of which 390 were primiparae and 289 multiparae; 115 were post-natal cases. Miss Ivens said that there had been no maternal mortality among these cases and no maternal morbidity as defined by the Central Midwives Board rules among the cases delivered in the home. Miss Ivens classified the cases as follows: Contracted pelvis occurred in 130 cases, the high percentage being probably due to the fact that a proportion of the cases were referred from outside clinics, doctors, and midwives for special observation and care. Of the total number of maternity cases (679) natural delivery took place in 601, or 88 per cent. Among the complications encountered were post-partum haemorrhage (3 severe and 2 slight), adherent placenta, perineal tears, fibromyomata, twin

births (8 pairs), unreduced occipito-posterior position, placenta praevia (8), prolapse of cord, pelvic presentations (25), face presentations (2), eclampsia (1), an emergency. Induction of premature labour was employed in 48 cases, delivery by forceps was effected in 30 cases, and 29 patients required Caesarean section. Of the infants 39 were stillborn or died in the first ten days, 22 being premature. Miss Ivens described 11 cases where there had been some morbidity not amounting to the standard recognized in the Central Midwives Board rules. Full details of this investigation would shortly be published. She recognized that it was unwise to draw definite conclusions from so small a number of cases, but she was inclined to believe that the results pointed to the following conclusions. Latent or pre-existing infection was responsible for a considerable percentage of cases of puerperal sepsis; the organism might not infrequently be isolated from the urine during pregnancy, and intermittent albuminuria during pregnancy was an indication for bacteriological examination of the urine. Cases should be removed from unsuitable surroundings, and the accommodation in homes should be sufficiently ample for patients to be admitted a day or two before labour was anticipated. A rigidly aseptic technique was important. Well trained midwives could deliver a very high percentage of maternity cases if ante-natal care had been given by a doctor, and if skilled medical help and, if necessary, institutional treatment could be obtained when required. In view of the need for study of the origin and character of the infecting organism in cases of fulminating puerperal fever, such cases should be placed at the earliest possible moment under the care of an obstetrical specialist and a bacteriologist.

Dr. VIOLET RUSSELL described the technique adopted in private cases, and emphasized the need for efficient sterilization of the surgeon's hands and of the patient's body. Gloves should always be used, and she did not consider that swabbing was much good. The vulva, vagina, and cervix should be freely painted with tincture of iodine.

Dr. E. PHILLIPS mentioned the contrast between home conditions found in the practice of specialists and those which obtained in the East End of London.

Lady BARNETT was specially interested in the cases described by Miss Ivens where there was a pre-existing focus of infection. She was abandoning the theory that wound infection was the most important cause of puerperal sepsis. The factors to be considered were: (1) the focus in the mother; (2) low resistance in the mother; and (3) infection by the attendant. A mask might be a more important preventive than a gown. She was not certain that the banished theory of air infection would not have to be recalled in view of some recent experiences of her own.

At a meeting of the Edinburgh Obstetrical Society held on February 11th, the President, Professor B. P. WATSON, in the chair, Mr. D. M. GREIG, conservator of the museum of the Royal College of Surgeons, Edinburgh, read a paper entitled "Is plagiocephaly ever a birth deformity?" Mr. Greig described typical plagiocephaly and its measurement, briefly indicating the usual causes to which it had been ascribed. While doubting whether decubitus could bring about plagiocephaly, he admitted that injury during birth was by no means always a precursor of the deformity. The formation of plagiocephaly had been ascribed to pressure during birth, especially in a flat or a Nägele pelvis; but he thought that the combination which contributed most commonly to it was a normal child, a young primigravida with a powerful contracting uterus, and a "justo minor" pelvis. He gave details of a case illustrating his remarks, with photographs of the infant, and he instanced several cases, reported by various writers, in which plagiocephaly had been associated with this combination. Mr. Greig then pointed out that if a normal head passing through a "justo minor" pelvis could bring about plagiocephaly, the same deformity ought to follow when an unduly large head had to pass through a normal pelvis. He gave particulars of three cases in support of this suggestion, illustrated by drawings, photographs, casts, and the actual skulls. In conclusion, he demonstrated other skulls in which, together with plagiocephaly, there was evidence of undue pressure during birth. He emphasized the difficulty in obtaining full and accurate details of the birth of any individual after the lapse of even a few months, and suggested that the solution of the question as to this cause of plagiocephaly lay with the accoucheur.

## Robieus.

### WALKER'S "DERMATOLOGY."

EIGHT editions in twenty-five years, the number attained by Sir NORMAN WALKER's well known textbook, must almost constitute a record among publications dealing with skin diseases, and at any rate ensures for it a prominent place among the "best sellers" of dermatology, a place that it thoroughly deserves. Modestly enough the author still persists in calling it an *Introduction to Dermatology*,<sup>1</sup> and states that it does not profess to deal with the rarer pathological conditions of the skin, such as are more fully discussed in larger works; but as a matter of fact there are few points of any importance which are omitted, although the plan of the book very properly demands the more generous allocation of space for the commoner diseases. Every writer who permits himself to produce a textbook betrays a special weakness for certain portions of his subject, and these usually form the most interesting part of the book. In this instance we would direct the reader's attention particularly to the subjects of dermatitis venenata and dermatitis atopica, which have always been favourite objects of study to Sir Norman Walker, and which lend themselves appropriately to treatment in his characteristic racy style. It is long since the entity "eczema" has been admitted to exist by the Edinburgh school, and here the term is mentioned only that it may be severely condemned and its use proscribed; whether anything is gained by substituting for it the word "dermatitis" is doubtful, and we are interested to note that even in these pages the author resorts to the term "eczema," permitting himself the luxury of employing it if only the printer will place it between inverted commas. In using any word the most important thing is that the writer and the reader should both understand clearly what it means, and if it is clearly understood that eczema is merely an inflammatory condition of the skin of unknown etiology but associated with certain features, what is the harm in employing this time-honoured term? If we may permit ourselves to criticize one omission it would be that there is no description of the primary lesion in syphilis; surely this comes within the scope of such a book. It is true that it is most often seen by the venereal specialist, who too seldom is a dermatologist; but surely the general practitioner has a right to be introduced to one of the most important manifestations of disease upon the skin in an introduction to dermatology. Similarly we think that there should be mention of rashes of the acute specific fevers, some of which are always cropping up, and have to be distinguished from other skin eruptions. These, however, are minor defects, if they be defects, in a deservedly popular manual, which has grown stouter with age but which still remains of convenient size. This is due to the care with which the inclusion of all modern advances in the subject has been balanced by a ruthless pruning of superfluous matter, or matter which has become obsolete. The result is a thoroughly up-to-date volume. A special word of commendation must be given to the excellent and numerous coloured plates. They had been growing in number in the earlier editions, and further additions have now been made. They are mostly taken from excellent wax models, and are far more lifelike than is usual even in more elaborate and expensive works. We have no doubt that the present edition will worthily uphold the tradition set by its predecessors and will soon be exhausted.

### DEVELOPMENTAL ANATOMY.

PROFESSOR AREY has published, as the title of *Developmental Anatomy*<sup>2</sup> suggests, a textbook which includes more post-natal development than most other manuals of embryology. The outline presented of the more important developmental changes manifested after birth is a very valuable addition; it is indeed to be hoped that in subsequent editions this

feature may be still further amplified, as it is of greater significance to the student of medicine than much of the detail which frequently obscures fundamental knowledge and principles.

The book is divided into three sections. The first deals adequately with the early stages of development, and although the accounts refer primarily to human and mammalian embryology, the requisite amount of comparative embryology is introduced. The second section traces the origin and differentiation of the organs and systems, the derivatives of the three germ layers being considered consecutively. The description of the various developmental processes are concise and very clear, and can readily be followed and appreciated by the junior student. At the end of each chapter is a list of the commoner anomalies, and in every instance a brief reference is made to the mode of occurrence. The third section consists of a laboratory guide for the microscopic study and dissection of chick and pig embryos. In this part the author acknowledges very free use of the text and illustrations of the well known manual by Prentiss. The inclusion of this section enhances the value of the book considerably and renders it a particularly attractive and suitable textbook of embryology for medical or science students, presenting as it does within the one cover both the systematic and practical aspects of the subject. References are given throughout to the more important papers on subjects of special interest or where considerable difference of opinion exists. The book is excellently illustrated by over four hundred figures, all of which are clear and serve their purpose admirably.

Professor Arey is to be congratulated on the production of a textbook of embryology which may be highly recommended and is likely to be used very widely.

### SYNTHESIS OF DRUGS.

*Organic Medicaments and their Preparation*<sup>3</sup> is an English translation of a textbook written a few years ago by Dr. E. FOURNEAU, the head of the laboratory for therapeutic chemical chemistry at the Pasteur Institute. He was invited to go to Madrid in 1917 to arrange and direct a course of theoretical and practical instruction in the synthesis of important drugs, and the volume under review was based on this course he arranged. The book is therefore of an introductory and illustrative character, for the author has selected certain typical processes which appeared to him to be of outstanding importance, and has given a full and detailed account of the problems they raise. This method has made it possible to produce an easily readable introduction to a very technical subject.

Dr. Fournau deals with all the problems concerned in the synthesis of drugs, for not only does he describe the chemical processes employed, but he explains also why one process is used in preference to another, and even describes the way in which the price of raw materials and the percentage yield of final product influence the cost of the synthesized drug.

The general purpose of the book is well stated by Dr. Roux in his preface, where he says of the book:

"Above all it is a programme. Research in chemotherapy is of little renown in our country. Most new medicaments that we use are of foreign origin. This comes about partly because we have few chemists who have specialized in drug synthesis, and further, because no instruction in the subject is given in either technical schools or universities. M. Fournau is a recognized missionary convinced of the need for making France no longer dependent on the foreigner for important pharmaceutical products."

Most of these words apply with equal if not greater force to our own country, and therefore we have special pleasure in welcoming an English translation of this work. It is divided into two sections. The first and larger gives a general description of the mode of preparation of a large number of drugs. The most important classes dealt with are antipyretics, hypnotics, antiseptics, local anaesthetics, and organic compounds of arsenic and mercury. A certain number of general problems are dealt with, and the author makes some very interesting remarks on the difficult

<sup>1</sup> *An Introduction to Dermatology*. By Sir Norman Walker. Eighth edition. Edinburgh: W. Green and Son, Ltd. 1925. (Demy 8vo, pp. xxviii + 375, 92 plates, 80 figures. 20s. net.)

<sup>2</sup> *Developmental Anatomy*. A Textbook and Laboratory Manual of Embryology. By Leslie Brainerd Arey. Philadelphia and London: W. B. Saunders Co. 1924. (Sup. roy. 8vo, pp. 433; 419 figures. 27s. 6d. net.)

<sup>3</sup> *Organic Medicaments and their Preparation*. By Dr. Ernest Fournau. Authorized translation by W. A. Silvester, M.Sc. Sheffield. London: J. and A. Churchill. 1925. (Med. 8vo, pp. x + 262; 22 figures. 15s. net.)

problem of the relation between chemical constitution and pharmacological action. He realizes the enormous complexity of this particular problem, and carefully avoids sweeping generalizations; consequently his ideas are of great interest and value. In the second half of the book detailed descriptions are given of the methods of preparing a large number of drugs on the laboratory scale.

The book is one that will be of great interest to all concerned in the synthesis of drugs; its special value depends, of course, on the fact that the author is a master of his subject, and hence everything that he says is of importance. The translation is excellent and the book is well got up and well illustrated.

#### MACCALLUM'S "PATHOLOGY."

THE fact that Professor W. G. MacCALLUM's *Text-Book of Pathology* has had such a successful career is ample justification for the novel method of presentation of his subject which the author first adopted. The third edition<sup>1</sup> has just appeared, but in the eight years since the book was published it has been revised and reprinted seven times. The general structure of this textbook differs from other systematic textbooks on pathology chiefly in the fact that it departs from the customary method of treating general and special pathology separately, and in the way in which it is planned to discuss disease as far as possible on the basis of etiology. Its beautiful pictures and the discursive style of the text have always made it an easy book for students and a pleasant field in which the teacher could browse. No doubt this book has often been taken down from the laboratory shelf to verify some small point, not to be replaced immediately the information sought has been obtained; it is apt to beguile the reader, enticing him to some stimulating thought. It teaches ideas rather than facts. The present edition improves on its predecessors chiefly in the chapters on rickets and diabetes, including in these subjects the new knowledge gained in the last four years; certain of the infectious diseases also, such as encephalitis lethargica and typhus fever, have been handled in a different way. A little has been added and a little taken away, but this trimming has not changed the distinctive character of the whole. Printed on thinner paper, it is slightly less bulky, but unfortunately still costs £2 5s.

#### OBSTETRICS.

THE fourth edition of Professor DE LEE's *Principles and Practice of Obstetrics*<sup>2</sup> has, according to the preface, been submitted to a thorough and painstaking revision, both in regard to text and illustrations. Some additions and alterations have been made, and unfortunately it has been found impossible to reduce the size of the volume, which remains encyclopaedic in its proportions, and therefore a book for reference rather than for the student. As is well known, Professor De Lee is the editor of the obstetrical volume in the Practical Medicine Series of "year books," and the secretarial organization used in that connexion must have made him familiar with all the obstetrical literature of the world in the last decade. Indeed, traces of this are to be found in this volume; there is so much in it that in many places the matter is not very coherently arranged; views and observations are mentioned which are really hardly worthy of consideration, and might have been eliminated during passage through the editorial mill. Readers in this country must bear in mind the fact that the book is intended, in the first place at any rate, for practitioners in the United States, where conditions in many respects are very different. For example, in this country there is not the same likelihood of practitioners undertaking such operations as Caesarean section in circumstances unsuitable and for indications of questionable validity.

There is a "tide of obstetric operating now prevalent with its resultant maternal and foetal mortality. While the expert obstetrician in his specialistically manned maternity hospital can obtain more

nearly ideal results from his work by extending somewhat the indications for interference, at the present time it is the general practitioner who conducts the largest number of the births, either in the home or in the frequently poorly equipped small hospital. He must be given advice and methods applicable to the milieu in which he works, and non-interference with the processes of Nature, with their careful supervision, i.e., watchful and armed expectancy, has been proved to give the best results. Accordingly the indications for Caesarean section, forceps, version, pituitrin, bag dilators, have been very closely drawn."

The "tide of obstetric operating" does not flow with such perilous force in this country, but "watchful and armed expectancy" ever remains the soundest general principle of obstetric treatment. A series of twelve new illustrations, showing the low cervical Caesarean section, have been inserted, and the editor expresses the hope that this procedure will be adopted for abdominal delivery, since he is convinced "that if it should become established practice when abdominal delivery is indicated, it will directly and indirectly reduce the present frightful mortality from Caesarean section." While we agree that the lower segment operation is a most valuable modification of the classical operation, it ought to be emphasized that it is an operation that can safely be undertaken only by one familiar with general abdominal operative technique, and we cannot entirely share the author's expectations of a greatly reduced mortality by the indiscriminate adoption of this method. As in previous editions, the illustrations are remarkably numerous and on the whole remarkably good. It is quite an education to turn over the pages of this book and look at the pictures. Both the author and the publishers are to be congratulated on a really very fine volume and upon the continued popularity which it evidently maintains.

Professor HENRY JELLETT is to be congratulated on the appearance of a ninth edition of his *Short Practice of Midwifery*.<sup>3</sup> The book is so well known that anything in the nature of a detailed review is quite unnecessary. Many generations of students, both in Dublin and elsewhere, have learned most of their midwifery from earlier editions: that now before us has been revised and brought into line with the latest generally accepted doctrines in midwifery, and particularly such as are taught at the Rotunda Hospital, Dublin. In the appendix is a summary of the carefully compiled statistics of this hospital for the past thirty-three years, covering more than 57,000 consecutive cases of labour—an exceedingly valuable piece of work in itself. The illustrations are clear and useful, and the size of the volume has been kept within limits which make it convenient for the use of the medical student. Altogether there is no sign of decrepitude in this volume, and we are quite sure that it will continue to be as popular as the preceding editions have been.

#### MALIGNANT DISEASE OF THE KIDNEY.

*Cancers du Rein*,<sup>4</sup> by LECÈNE and WOLFROMM, forms part of the Bibliothèque du Cancer, published under the direction of Professors Hartmann and Bérard. Under the term "cancer" the authors include malignant growths of all kinds, whether sarcoma or carcinoma. These growths are among the most frequent of those met with in early life, representing from 38 to 50 per cent. of the tumours of infancy. The classification of carcinomas adopted is:

1. Tumours derived from the renal epithelium, subdivided into tubular and papillary carcinomas;
2. Tumours derived from adrenal rests—namely, hypernephromas; and
3. Tumours of the renal pelvis subdivided into papillary and non-papillary carcinomas.

The non-papillary tumours are classified as squamous, alveolar, and adenocarcinomas.

While devoting a separate section to hypernephroma, the authors state that the nature of this growth is still obscure and it is impossible to affirm that it is really due to aberrant inclusions of adrenal tissue. The frequency of its occurrence has been overestimated in recent years, and it is often impossible to say whether a renal tumour is a hypernephroma or derived from the renal epithelium.

<sup>1</sup> *A Text-Book of Pathology*. By W. G. MacCallum. Third edition, thoroughly revised. Philadelphia and London: W. B. Saunders Company, 1924. (Sup. roy. 8vo, pp. xv + 1162; 575 figures, 45s. net.)

<sup>2</sup> *The Principles and Practice of Obstetrics*. By Joseph B. De Lee, A.M., M.D. Fourth edition, thoroughly revised. Philadelphia and London: W. B. Saunders Company, 1924. (Sup. roy. 8vo, pp. xv + 1123; 1,128 illustrations on 523 figures, 201 of them in colour, 55s. net.)

<sup>3</sup> *A Short Practice of Midwifery*. By Henry Jellett, B.A., M.D. Dublin Univ., F.R.C.P.D. Ninth edition. London: J. and A. Churchill, 1924. (Post 8vo, pp. xvi + 591; 258 figures, 18s. net.)

<sup>4</sup> *Cancers du Rein de la Glande Surrenale et des Voies Urinaires Supérieures*. Par P. Lécène et G. Wolfromm. Paris: Gaston Doin, 1923. (Roy. 8vo, pp. 207; 32 figures. Fr. 15; franco, fr. 36.50.)

The presence of doubly refracting lipoid is not characteristic of hypernephroma, since it occurs in chronic nephritis and in epithelial tumours of other organs. The presence of lecithin is probably of more importance as indicating a relation to the adrenal gland. Speaking of the lymphatics of the kidney, the authors state that they pass in a kind of mesonephron into the lateral aortic glands, the posterior lymphatics going to the upper, the anterior lymphatics to the lower set. They are numerous and lie in very vascular tissue, and although it has been recommended that they should always be removed the operation is difficult and dangerous. Haematuria may precede the other symptoms by several years—eleven and a half years in one case—showing that the evolution of a renal carcinoma may be long. The duration of life after the tumour has been recognized may also be relatively long; Gillet mentions six cases of survival for from ten to sixteen years. Carcinoma of the kidney recurs after nephrectomy in the proportion of 80 per cent.; in 100 cases 22 died from the operation, and of the 78 survivors there was rapid recurrence in 61, while in 16 only was there prolonged survival. With regard to carcinoma of the pelvis, Derovenko in 54 cases, of which 30 were operated on, witnessed rapid recurrence in the majority. Necker observed a recurrence in the form of vesical papilloma six months after nephrectomy, and Asch a similar recurrence ten weeks after the operation.

### NOTES ON BOOKS.

It is not surprising that Professor FINDLAY'S volume *Chemistry in the Service of Man* should have reached a third edition.<sup>8</sup> The basis of the little work is a course of lectures delivered in 1915 to an educated audience without any knowledge of the science of chemistry, and as published it is intended for readers of that class. The present edition is brought up to date by the introduction of three new chapters on (1) radio-activity and atomic structure, (2) the rare gases of the atmosphere, and (3) metals and their alloys. From beginning to end it is clearly and attractively written, needless technicalities are avoided, yet it is pervaded by the spirit and character of really scientific instruction, so that it is not to be galloped through with novel-reading speed. A brief historical introduction, beginning with the philosophy of Empedocles and Aristotle, is a notable feature. In these times doctors have a hard task to maintain even a reasonable acquaintance with the advances in strictly professional knowledge; yet if a man does want to bring up to date his acquaintance with the chemistry he was taught at college he can not do better than spend an occasional hour over the Aberdeen professor's new edition.

We ought to have announced long ago that Professor PICKERILL'S book on *The Prevention of Dental Caries and Oral Sepsis* had reached a third edition.<sup>9</sup> A large part of it is devoted to an elaboration of his now well known thesis that the safeguard against all dental ills is a plentiful flow of alkaline saliva. The criticism that was made on the appearance of his first edition that adhesive food covered by mucus defies all the powers of abundant and alkaline saliva appears to us still to remain unanswered. Indeed, Professor Pickerill is disinclined to recognize this particular property of food-stuffs, and though he has invented a new and terrible word, "lodgeability," and has divided foodstuffs accordingly, he seems to attach more importance to the circumstance that the "lodgeable" articles "are originally either alkaline or neutral in reaction," while the "unlodgeable" are "originally acid in reaction," than to adhesiveness or the reverse. Briefly the theory is that slightly acid and sapid foods produce an abundant and prolonged secretion of highly alkaline saliva which will neutralize the acid formed from carbohydrate debris and so will prevent dental caries, while alkaline and tasteless foods produce only a limited flow of less alkaline saliva useless as a preventive. To it has been objected that the flow of saliva is not continuous and that mucus, which soon coats all food debris, and perhaps the debris itself, is impermeable to saliva. This latter point touches the vexed question of the hardening of enamel after eruption of the tooth, and in this connexion the author states that mucus is a non-electrolyte and that hence viscous saliva would hinder the diolysis necessary to the hardening. In addition to saliva

the author has explored practically every avenue by which the discussion of dental caries can be approached, and his experiments, observations, and conclusions are clearly and concisely stated. No point is too trivial for notice and no problem too impeachable for attack. Occasionally his observation seems to be at fault, as in his failure to find constriction of the jaw before the age of 6, and occasionally we may question his data, as with regard to the storage of berries by the Eskimos or the extent of dental caries among the Guachos; but the reader's interest is kept keenly alive and our critical faculties are thoroughly roused from cover to cover.

Dr. CECIL WEBB-JOHNSON has written a book entitled *Woman's Health and Happiness*,<sup>10</sup> the object of which is to help the average woman to a better and clearer knowledge of herself, and thus to prevent ignorance and false ideas from wrecking lives which should be serene and bright. The author takes his readers through the various biological epochs with their surrounding duties and dangers, and among the topics considered are some aspects of marriage; sexual love; the expectant and nursing mother; food and good health; exercise, dancing and other recreations; nerves; women and employment; obesity; the approach of age; and danger signals. The book contains much common-sense advice, is wholesome in tone, and may be recommended as a useful guide to those for whom it is intended.

The fifth edition of Waller's *German-English Medical Dictionary*<sup>11</sup> has been improved and enlarged by M. WHITE, though the actual size of the volume has been decreased. A considerable number of new words have been added, particularly with reference to anatomy and chemistry, but there is still some uncertainty about pathological terms, as in the previous edition. In some cases short definitions are given and descriptions of the composition of certain remedies. The third edition of the *English-German Medical Dictionary*<sup>12</sup> of WALLER and KATZ includes a large number of technical terms, together with many simple words which can be found in the ordinary dictionary. It will probably prove of more use to German readers of English books than to English students of German.

The forty-fourth volume of the *Transactions of the Ophthalmological Society of the United Kingdom*<sup>13</sup> is well up to the standard of previous issues, both in the interest of its contents and in the excellence of its illustrations. A considerable part of the book is devoted to the Oxford Ophthalmological Congress of 1924, and the annual reports, are published of the Midland, the North of England, and the Irish Ophthalmological Societies. Included in the list of communications made to the Ophthalmological Society of the United Kingdom during the year under review is a report of the discussion of the physiology and pathology of the pupil-reaction.

The *Medical Register*<sup>14</sup> for 1925 contains 49,958 names, as compared with 48,140 for last year. During the year 2,796 names were added, and of these 1,190 were registered in England, 935 in Scotland, and 441 in Ireland; 226 were colonial, and 4 foreign. There is again a considerable increase in the numbers registered in Great Britain and Ireland, and both the total of registrations and the numbers registered in each of the three countries are the highest yet recorded. The number of names removed from the *Register* was 978, being 55 more than in the previous year. Of these 849 were removed on evidence of death; 124 because of failure to reply to the inquiries of the Registrar as to cessation of practice or change of address; and 5 were struck off the *Register* under the disciplinary powers conferred on the General Medical Council by the Medical Act of 1858. The large number of new registrations during the year has caused an increase of some forty pages in the size of the volume. The *Dentists Register*<sup>15</sup> for 1925 has been issued simultaneously. It contains 13,818 names, representing an increase of 345 over the corresponding figure in the previous volume. During the year 524 dentists were registered with qualifications and 210 without; 524 names were restored and 916 were removed from it for various causes, including 147 on evidence of death. The *Register* this year contains for the first time a local list of names, the London names being grouped under the postal

<sup>8</sup> *Chemistry in the Service of Man*. By Alexander Findlay, M.A., D.Sc., F.I.C. Third edition, revised and enlarged. London and New York: Longmans, Green, and Co. 1925. (Cr. 8vo, pp. xix + 300; 25 figures, 4 plates. 6s. net.)

<sup>9</sup> *The Prevention of Dental Caries and Oral Sepsis*. By H. P. Pickerill, C.B.E., M.D. Third edition. London: Baillière, Tindall and Cox. 1923. (Demy 8vo, pp. xii + 340; 80 figures. 18s. net.)

<sup>10</sup> *Woman's Health and Happiness*. By Cecil Webb-Johnson, M.B., B.Ch. London: Methuen and Co., Ltd. 1925. (Cr. 8vo, pp. xii + 242. 6s. net.)

<sup>11</sup> *German-English Medical Dictionary*. By Joseph R. Waller, M.D. Fifth edition, improved and enlarged by M. White, M.D. Leipzig and Vienna: F. Deuticke. 1925. (Med. 16mo, pp. 383.)

<sup>12</sup> *English-German Medical Dictionary*. By Joseph R. Waller, M.D., and Moritz Katz, M.D. Third edition. Leipzig and Vienna: F. Deuticke. 1925. (Med. 16mo, pp. 193.)

<sup>13</sup> *Transactions of the Ophthalmological Society of the United Kingdom*. Vol. xlv. Session 1924. London: J. and A. Churchill. 1924. (Demy 8vo, pp. ii + 452; 43 figures, 18 plates. 30s. net.)

<sup>14</sup> London: Constable and Co., Ltd. *Medical Register*, £1 1s.; *Dentists Register*, 12s.; *Students Register*, 7s. 6d.

districts and subdistricts, the remainder under the cities, towns, or villages in each country. The Navy now has 43 dentists, the Army 75, the Royal Air Force 27, and the Indian Medical Service 1. The General Medical Council has lists of medical and dental students' numbers with 545 in 1923 and 1,833 in 1922; Scotland again heads the list. Registrations of dental students numbered 200, as compared with 107 in 1923 and 424 in 1922.

The *Alliance Year Book and Temperance Reformers' Handbook for 1925*<sup>15</sup> gives a review of the situation in the different countries of Europe. The position of temperance legislation in the British Commonwealth during 1924 is explained, and, under the heading of "Some medical aspects of total abstinence," the publication of the Medical Research Council, entitled *Alcohol: Its Action on the Human Organism*, is considered, and also Professor Starling's *The Action of Alcohol on Man*. Several statistical tables are supplied.

<sup>15</sup> *The Alliance Year Book and Temperance Reformers' Handbook for 1925*. Edited by George B. Wilson, B.A. Lond. London: United Kingdom Alliance and Hendley Brothers. 1925. (Deary 8vo, pp. 262, 2s.)

## MEDICAL AND SURGICAL APPLIANCES.

### OUTLINE DIAGRAM OF THE LARYNX.

#### Rubber Stamp.

SIR STCLAIR THOMSON writes: The conventional diagram of the larynx has descended to us from the early days when the chief interest of a laryngeal case was "to see the cords" and anything growing thereon. This diagram was particularly

unsatisfactory for displaying the interarytenoid region which, with the neighbouring area above each vocal process, is the most frequent site for the deposit of tubercle. Dr. H. Smurthwaite has most kindly come to my assistance with his artistic skill in making a design to my suggestion. The outline drawing here figured is, of course, semidiagrammatic, for it is impossible in

the larynx to view both the interarytenoid region and the laryngeal surface of the epiglottis at one and the same time. Still, this conventional outline will enable laryngologists to indicate changes in any part of the larynx, including the posterior wall, both sides of the aryepiglottic folds, the sinus pyriformis, and the post-crioid region—all of which are inadequately represented in the usual diagram of the larynx. This rubber stamp has been put on the market by Messrs. Mayer and Phelps, 58, New Cavendish Street, London, W.1.

## ROYAL COMMISSION ON LUNACY AND MENTAL DISORDER.

(Continued from page 351.)

### EVIDENCE OF NATIONAL ASYLUM WORKERS' UNION.

At the sitting of the Royal Commission on Lunacy Law and Administration on February 24th, with Mr. N. MICKLETH, K.C., deputy chairman, presiding, evidence was taken from the National Asylum Workers' Union, which, it was stated, comprised 11,000 members working in 128 institutions in Great Britain. The evidence was tendered by Mr. Walter Blood and Mr. George Gibson, respectively president and honorary secretary, and by Miss Maud Wiese, chief charge nurse at Claybury.

In its evidence the Union advocated that the mental health authorities should have powers conferred upon them to inquire into the incidence of insanity in their respective areas, to provide out-patient clinics at mental hospitals, and to organize similar clinics in conjunction with general hospitals, and they should be able to commit patients for treatment for a limited period without certification. The Union held that the conducting of mental hospitals as profit-making institutions should be abolished. Another reform which was urged was that medical superintendents should confine themselves to medical affairs, whilst still retaining the guiding disciplinary authority in the institution, but with powers of suspension only. Medical superintendents were professional men, and it seemed absurd that their energy should be wasted in office routine as at present. The minimum proportion of medical officers to nurses should be defined by law, and in the case of nurses at least 50 per cent. of the whole staff should be qualified mental nurses. It was stated to be no uncommon occurrence under existing conditions for a nurse to be left alone during the day-

time with thirty or even fifty patients, and an instance was known to the witnesses in which a nurse had control in the airing court of over a hundred patients. This constant understaffing was detrimental to the patients and unfair to the staff. A proportion of one to ten on actual duty should be insisted on. The introduction of female nurses into male wards was deplored. Over 10 per cent. of the male cases of insanity were of syphilitic origin, and many more of the patients were sexually abnormal, and their conduct could not be predicted. With regard to private mental hospitals, the experience of the witnesses was that these were constantly changing their staffs, and that little effort was made to engage or retain qualified mental nurses. A further objection was that the greatest safeguard of the personal liberty of the patients—namely, regular visitation by a publicly elected committee—was absent.

The witnesses believed many criticisms of the lunacy system to be well founded, but strongly denied that cruelty to patients was at all common. It had to be remembered that the mental nurse was compelled to put up with abuse and assault by patients daily, and occasionally the provocation to retaliate overcame the will. The chief trouble was the constant changing of staff in mental hospitals, and in nine cases out of ten it was the inexperienced nurse who was at fault when any breach of discipline occurred. The vast gulf between mental and general nursing was pointed out. The general nurse performed her duties among sane people, who retained the instincts of decency and good conduct, and were inmates of the hospital of their own volition, and were generally grateful for what was done for them; the mental nurse had to carry out her duties amid circumstances generally the opposite to these in every respect. Only by the general adoption of the three-shift system—already widely adopted in the Midlands—could justice be done to patients in mental hospitals. Among reforms suggested by the Union on behalf of patients were the following: that certification should not be resorted to until after at least three months' treatment; that the principle of single care should be extended; that the dietary in institutions should be improved and a light supper instituted; that more outdoor recreation should be provided; that there should be a system of credit vouchers to patients who did useful work; and that nurses' key chains should be abolished. The Association also urged that, to protect the staff, special disorders common to mental hospitals should be scheduled as "industrial diseases" under the Workmen's Compensation Act; these were colitis (asylum dysentery), typhoid, and phthisis.

Asked whether there was an excessive use of sedatives or purgatives in mental institutions, Mr. Blood replied strongly in the negative. Croton oil he had never known to be used in his experience of asylums. As to sedatives, the only drug given was a sleeping draught, and that but seldom. Miss Wiese said that in her experience these things were not given unless they were absolutely necessary, and even when the patient had been put upon any of them it was within the nurse's discretion to withhold. Mr. Gibson said that twenty years ago it was the custom to have a stock-pot apertent, but to-day nothing of the kind was given unless it was definitely prescribed, and it was the practice to return into store such medicines as were not administered.

### THE EVIDENCE OF DR. LOMAX.

At the sitting of the Lunacy Commission on February 25th the evidence of Dr. Montagu Lomax, author of *The Experiences of an Asylum Doctor* (1921), was taken.

The Chairman (Mr. H. P. MACMILLAN, K.C.) said that the Commission had had the advantage of reading Dr. Lomax's most interesting book, also the Cobb Report and Dr. Lomax's reply thereto. He wished to pay a tribute to the very great care Dr. Lomax had taken in considering this whole topic and the zeal he had shown in elucidating it. As the Commission had already received evidence from the National Society for Lunacy Reform, he thought it would be well if Dr. Lomax confined himself to those points on which, he understood, the witness was not in entire agreement with the proposals of the society.

#### The Position of the Medical Superintendent.

Dr. Lomax said that he had been for many years in general practice, and was now doing mental work. His interest in this topic of lunacy reform originated in the service in which he was engaged in two asylums—Lincoln and Prestwich—during the war. In consequence of his experiences in those two asylums he came to the conclusion that the present system stood in need of reform. He dealt first with the position of the medical superintendent. He urged an entire separation of the offices of medical superintendent and executive chief of the institution. This was specially necessary in large asylums, containing more than 1,000 patients. The Chairman suggested that if this large type of asylum, of which there were a good many examples in this country, gave place to the more modern form of villa asylums, with a limited number of inmates in each institution, the objection would disappear. Dr. Lomax maintained that it would still exist; villa asylums, as a rule, were not small, they were on a different system, and the medical superintendent of such institutions would still have to be appealed to on all sorts of questions involving responsibility.

The Chairman: The treatment of mental patients differs from the treatment of ordinary patients in this respect, that curative treatment in the former case must necessarily bring in questions of environment, occupation, recreation, &c. so forth to a very large extent. The medical doctor, therefore, is interested in many matters in which the ordinary physician has no concern. If you remove the medical superintendent from his control over the whole establishment the result might be to interfere with the very means most desirable in the treatment of the cases.

Dr. Lomax: In everything affecting the welfare of the patient the

medical superintendent must, of course, be supreme, but the appointment of the various outdoor officials and workpeople, such as engineers or farm hands, does not seem to be part of the superintendent's work at all.

The Chairman: But suppose the supervisor in a workshop was tactless, ought not the medical superintendent to be allowed to intervene?

Dr. Lomax: Certainly; that is part of his department, but I am thinking of the medical superintendent's engrossment in clerical and administrative work generally. He has in his hands the ordering of the whole establishment from the executive point of view—for example, alterations and repairs to buildings, engagement and discharge of workmen.

The Chairman: But if I were a medical superintendent, I should be very interested in getting my ideas carried out.

Dr. Lomax: There is surely no need for that. The medical superintendent is engaged in painting, the engineering and electrical work, the stores, and so forth. I have known superintendents spend the whole morning in their office dealing with accounts.

The Chairman: But even the choice of wallpaper might have a medical importance.

Dr. Lomax went on to say that an asylum committed thought much more of a medical superintendent who was a good executive officer than of one who was a good medical man. He was regarded as a good superintendent if he economized. He had a free hand in the wards so long as he kept expenses down. The Chairman asked what was his security of tenure, and Dr. Lomax replied that there was none at all; his tenure depended on the whim of the asylum board, and as long as he ran the asylum economically, however unpopular he might be with the patients, he would be as difficult to remove as a clergyman from a country living. He (the witness) was in favour of the medical superintendent being appointed by the Ministry of Health. Earl Russell asked if a superintendent who made reports involving capital expenditure and advocated reforms would lose his job. Dr. Lomax said that he did not think he would lose his job, but he would be warned that those were not the kind of reports he was expected to make. He was of opinion that it would be better for an asylum to be governed by a lay superintendent, and for the present superintendent to be a senior medical director. The Chairman said that in that case a progressive medical man might be hindered in his justifiable work, and the layman might not appreciate medical requirements. He had difficulty in seeing that any province could be withdrawn from the medical man. The two solutions might be the delegation of some routine work to efficient subordinates. Dr. Lomax said that seven-eighths of the superintendent's work was at present executive. The superintendent ought to go round the wards with his officers, but in the majority of cases this was never done. In many instances a patient was never seen by the medical superintendent at all.

Before passing from the subject of the medical superintendent, Dr. Lomax referred for corroboration to the report of the conference of medical superintendents held under the chairmanship of Sir Frederick Willis in 1922, and quoted some statements from medical superintendents themselves, including one by Dr. M. A. Archdale, that the medical superintendent was a sort of mixture of prison governor and hotel manager (*BRITISH MEDICAL JOURNAL*, January 25th, 1922, p. 149).

#### *Alleged Ill Treatment of Patients.*

On the subject of ill treatment of patients, Dr. Lomax said, in reply to the Chairman, that he had never actually seen any cases of ill treatment by an attendant—indeed, the doctor was the last person to see such cases—and he feared that in some instances the patient was too cowed to make a complaint, fearing what might happen to him at the hands of the attendant afterwards. Asked by the Chairman whether he did not think that instances of ill treatment occurring while he himself was a doctor in an asylum would be of more value than the repetition of hearsay evidence of alleged cases years after leaving the asylum service, he said that he appreciated the Chairman's point, but while he himself was engaged in the work he had not suspected what he now believed went on.

The Chairman: It is a very serious allegation to make against attendants, first that they are cruel (although you have not seen instances of it yourself), and that then, when they are taken to task by the authorities, they visit it upon the patient.

Dr. Lomax: I am only the spokesman of patients who came to me. I do not speak of anything I have myself observed in the asylum. But I believe there are such cases, hundreds of thousands of them.

The Chairman: Hundreds of thousands!

Dr. Lomax: Yes, all over the world.

The Chairman: My colleagues and I are satisfied that cases of cruelty, possibly of gross cruelty, do occur, but it does not assist us very much to carry the matter into the region of statistics. Such cases must occur inevitably, just as accidents happen on the best administered railways. The problem which interests us is how that kind of thing can be stopped. Your outlook seems a little pessimistic. You tell us that the medical superintendent is a remote person who does not see anything or is kept in ignorance of what is going on. How are we to get the facts? The patients will not make statements.

Dr. Lomax: Out of the asylum they will. What converted me into a lunacy reformer and a critic of the administration was the volume of this testimony, its character, spontaneity, and consistency, from hundreds of sources.

Lord Russell: You do not tell us what value you yourself attach to these complaints.

Dr. Lomax: I attach the greatest value. It took me two years to convince myself, and then I became an absolutely convinced man.

The Chairman: That is a generality. Take a thousand cases, investigate them with such means as are at your disposal, how many would you find well founded?

Dr. Lomax: I think in every case the patient was telling the truth about the facts that had occurred. His charges were specific. They dealt with names and dates and persons. There was no reason why he should be lying, and, if not lying, the only other possibility is that he may have been deluded. But these are specific assertions made by people who left the asylum perhaps years ago and are living normal lives and are of sound mind.

The Chairman: Do you believe them all?

Dr. Lomax: By no means all, but the great majority.

The Chairman: What is your criterion for distinction between those which are true and those which are not?

Dr. Lomax: To certain trivial things I do not pay much attention, but when it comes to broken limbs and patients practically killed, there is not much question of a dividing line.

Mr. Snell: Do these allegations of cruelty extend to the female side?

Dr. Lomax: Certainly. You hardly find a case, if the patient has been in the asylum for any length of time, in which there are not allegations as to cruelty, either inflicted upon himself or observed by him to be inflicted upon others.

Sir D. Drummond: What steps did you take to corroborate their statements?

Dr. Lomax: I took it that the corroboration would be sought by the present inquiry.

The Chairman: You transfer to us the evaluation of your evidence?

Dr. Lomax: The only way to proceed is to take specific instances and examine judicially.

Lord Russell: Short of admission by one of the parties incriminated, should we get any corroboration?

The Chairman: You have had a number of complaints of ill treatment and have tested them as far as you could. You are entitled to draw from that the inference that the convergence of testimony from different sources demonstrates that in fact a considerable amount of ill treatment does go on at the hands of asylum attendants. Many of the cases if explored would turn out to be exaggerated, others might prove to be absolutely trustworthy, but the fact that a large number of complaints have been made converging to one result seems to me to demonstrate that this thing does occur. I do not see, however, that we should be very much advanced if we investigated, say, twenty cases, and found ten proved and ten disproved.

Dr. Lomax: I am asking you to hear not only ex-patients but ex-attendants, some of whom are prepared to come forward and testify.

In further evidence Dr. Lomax referred to a case, particulars of which he had already sent to the Commission, concerning a patient who had died. He held that in the case of all deaths in asylums the medical superintendent should be made responsible for reporting to the coroner any marks of injury or other suspicious circumstances. The Chairman said that the case in question was very fully investigated and reported on to the Board of Control. He had had all the papers before him. Dr. Lomax said that the attendant who had originally reported the case had also made a statement to the Board of Control, and had asked to be called in any inquiry. The Chairman remarked that he did not want to enter into the circumstances, but he understood that the attendant was in the hands of the police at the time. Dr. Lomax denied that this was the case. The complaint was three years old, but the circumstances which had brought the attendant into the hands of the police were quite recent. The Chairman said that he understood that this particular attendant was dismissed from the asylum service for suspected theft. Most of those engaged in law did not pay much attention to allegations made by persons of that character. Dr. Lomax said that he could bring corroborative evidence from outside eye-witnesses independently of this attendant.

A little later the Chairman announced that he and his colleagues were impressed by the suggestion that one or two ex-patients and one or two ex-attendants might usefully be examined, and he invited Dr. Lomax to furnish the Commission with names.

#### *Procedure for Detention.*

On the question of the detention of the harmless but at present certifiable person, Dr. Lomax said that he favoured the boarding-out system as operating in Belgium; there patients were detained but uncertified, thereby avoiding stigma. Under the present law people could be far too easily put away in asylums and kept there. He thought there should be first a medical certificate, called a preliminary detention certificate, to be produced in the case of any person with suspected mental disorder on admission to a mental institution; this certificate should give the medical officer in charge of that institution power of detention for a certain period. A second certificate should afterwards be required if the patient had not in the meantime been discharged, and this should be signed, where possible, by a diplomat in psychological medicine, and countersigned by a magistrate. His great point was that every mental patient should have, say, twenty-eight days in a sort of half-way house for observation and preliminary treatment. Voluntary boarders entering the observation building should sign a document conferring the right of detention for twenty-eight days as a safeguard against a sudden attack of insanity of an impulsive character. With regard to private asylums, all those which Dr. Lomax had seen were well conducted. He believed the private asylums of England were as well conducted as any in the world. The objection to them was the existence of the financial motive, but he agreed that the good recovery rate did not support any allegation that a financial motive was operating to detain a patient after he had recovered.

#### *Evidence of Ex-Patients.*

The Chairman stated, before Dr. Lomax gave his evidence, that the Commission had had to reconsider its procedure with regard to hearing the evidence of ex-patients tendered by the National Society for Lunacy Reform. The original apprehensions of the Commission that a public inquiry might prove very disquieting to an ex-patient had been justified, and in addition the procedure adopted had had the result of creating an atmosphere of controversy and recrimination which the Commission could not allow to recur. In future therefore, ex-patients would not be exposed to the ordeal of public examination; such witnesses would be examined in private, though it was not intended to exclude the chairman and counsel of the National Society for Lunacy Reform, which was tendering the witnesses. The evidence, with the names omitted, would in due course be published.

## Nova et Vetera.

### MEDICAL BIOGRAPHY.

IN 1838-40 appeared Thomas Joseph Pettigrew's *Medical Portrait Gallery: Biographical Memoirs of the Most Celebrated Physicians, Surgeons, &c., who have Contributed to the Advancement of Medical Science*. The work was illustrated with five portraits, and contained most eulogistic and redundant accounts of medical men, still living, and in some cases, such as that of Sir James Annesley, nowise deserving the minute attention bestowed upon them.

Old files of medical journals will perhaps throw light on the manner in which Pettigrew's book was received by contemporaries, but we know of no outcry against its appearance such as was raised against the *Medical Circular*, probably from 1852 onwards, for publishing puffs—for they were little else—accompanied by fine wood engravings, of the medical practitioners of the fifties of last century. In 1854 a "strong and very general verdict of condemnation" was pronounced against the practice of publishing "biographies of living members of the medical profession," and at the general meeting of the British Medical Association, held at Leamington in August, 1865, Dr. Stewart (London) carried a motion to the effect "that this meeting sees no reason to dissent" from this pronouncement.

The occasion of this resolution was the publication of certain lives of eminent living medical men by Dr. Herbert Barker of Bedford. These lives were accompanied by photographs, and, at the time of the debate, did not amount to more than three biographies of medical men of the first reputation. At the time of his death, towards the close of the year, only four such lives had been published, and the collected work did not make its appearance until 1867-8, when a quarto volume was issued with the title *Photographs of Eminent Medical Men of all Countries, with brief Analytical Notices of their Works*. The letterpress was by Barker, and the photographs were by Ernest Edwards.

Barker's notices, though diffuse according to modern ideas, were not objectionable. He avoided, he said, all personal details. The debate, however, condemning his first three lives, and with these his whole subsequent undertaking, was sufficiently condemnatory. In October, 1865, the *BRITISH MEDICAL JOURNAL*, in an article on contemporary biography and the whole question at issue between Drs. Barker and Stewart, was prompted to ask:

"What if contemporary biography is to become a recognized and accepted act of professional propriety, what reason is there why we should not nil and each of us do that very thing which Dr. Barker now proposes to do for us; viz., issue to the profession and the public a calm and modest and truthful account of what we are, what we have done, and what we are doing, adorn it with our photographic presence, and thus scatter our virtues and facial fames throughout the world?"

Yet some of the most valuable medical biographies are autobiographies. Some dozen stand out in recollection, notably those by Sir Benjamin Brodie, Dickinson Webster Crompton, Nelson Congreve Dobson, Michael Lambton Este (Nelson's naval surgeon), Joseph Fayer, Frederick James Gant (who put his recollections in the form of a novel), Henry Power, Augustin Pritchard of Bristol, Sir John Simon, Henry Smith, W. D. Spanton, and Jonathan Toogood. So rare are some of these books, so full of long-forgotten detail about apprenticeship and the lives of the old students and the customs of old hospitals prior to 1850, that one is almost tempted to wish that autobiography had been much more widely written than it has been.

The autobiographer, indeed, is the medical historian's best friend. He writes as a rule in old age, and, far from indulging in self-advertisement, is prone to amiable self-depreciation and to revelations of character, for which we should often look in vain in the pages of his official eulogists. Thus Mr. William Clapton, M.B., F.R.C.S., some time vice-president of the Hunterian Society, and well known in Canterbury, where he died in 1912, used to tell of the rhyme

with which the street boys of the time of the Great Exhibition of 1851 were wont to taunt the luckless apprentices sent out with baskets of medicines by the general practitioners of the time.

"O salts and scum, you would not do for me;  
I'd rather go to Jericho than a doctor's boy I'd be."

Clapton was bred in a hural school and practically educated himself from the early period at which he left Christ's Hospital to the time when, by sheer pluck and perseverance, he was able to enter himself as a student at St. Thomas's. He became literary, employing his meal times in running for books to a library. Gibbon, Grote, and Adam Smith were devoured by the young apprentice, whose memory was so retentive that he could in time repeat the whole of *Paradise Regained*, as well as the Prayer Book version of the Psalms.

The late Mr. Henry Power describes remarkable early experiences in his charmingly written autobiography. His bedroom was rather more luxurious than the lair underneath the counter usually assigned to apprentices.

"It contained an escritoire, a camp bedstead, and a miserable washstand. For fear of my setting the house on fire I had a wire gauze candlestick with a dip inside it, always excessively dirty. Beneath the bed were, what I did not much fancy, a number of perfectly black, injected, shrivelled dissections of arms and legs."

This was in 1844. Young John Higginbottom, afterwards F.R.S., in 1816 underwent much indignity and hardship.

"I had to groom the horse, take it to water night and morning, sweep out the surgery daily, clean all the shop bottles and shelves every third morning, make all the preparations, powder barks and cantharides, and pass them through a fine sieve. I had to make all ointments and plasters, and keep a large stock of pills ready. As there was no fire in the surgery during the coldest weather, my hands were often chapped."

At an earlier date still young Charles Mayo of Winchester was first led to study anatomy by a chance visit to a gallows where, in the open air, hung the skeletons of murderers. Like Tennyson's Rizzani, that tragic mourning mother, he collected the fallen bones, but with a different purpose.

When we come to early practice involving great feats of horsemanship on unmacadamized country roads, the insanitary state of the old hospitals, the primitiveness of urgency surgery performed by candlelight, and a host of similar subjects, it is to the old autobiographers that we turn, or to those autobiographical touches which occur in the midst of the often trite eulogies of the elder biographers.

VICTOR PLANN, M.A.,  
Librarian, Royal College of Surgeons of England.

### ROYAL MEDICAL BENEVOLENT FUND.

At the last meeting of the Committee twenty cases were considered and £378 voted to sixteen applicants. The following is a summary of some of the cases relieved.

Widow, aged 47, of L.M.S.S.A.Lond. who died in 1924. She has tried to support herself and children by keeping a boarding-house; this failed, but she is likely to obtain a post as nurse mistress in a school on the South Coast, when she can have her daughter, aged 4, with her. She asked for £12 to cover three weeks' board and lodging in London, fares for self and child to settle up her affairs in the Midlands before taking the post. Voted £20.

Widow, aged 37, of M.B.Olas. who died in 1922. She has three children aged 10, 8, 6; her total income is 30s. a week, and she has been only able to earn very little by needlework. She was in hospital during the autumn to undergo an operation, has run into debt, and school fees are owing. Voted £5, and £20 in four instalments.

Widow, aged 87, of M.R.C.S.Eng. who died in 1895. She is bedridden and has to have a nurse at night as the daughter, aged 57, is only able to look after her during the day. Her total income is £100, and the rent is £39 a year. Voted £5, and £25 in four instalments.

Widow, aged 71, of L.R.C.P.Ed. who died in 1918. She has cataract and is only able to do a little knitting, by which she earned £3. She is looked after by her youngest daughter, who is only able to do a little spinning. The applicant's income is £34 a year from property and the daughter's £10. Voted £18 in twelve instalments.

Subscriptions may be sent to the Honorary Treasurer, Sir Charters Symonds, K.B.E., M.S., at 11, Chandos Street, Cavendish Square, London, W.1.

The annual general meeting of the Royal Medical Benevolent Fund will be held at 11, Chandos Street, W.1, on Tuesday, March 17th, at 5.30 p.m., when the annual report and financial statement for the past year will be presented and the officers and committees elected.

# British Medical Journal.

SATURDAY, MARCH 7TH, 1925.

## POST-GRADUATE ORGANIZATION IN LONDON.

For some time many of those interested in seeing established in London a complete organization for post-graduate medical study have had to view with a growing feeling of disappointment the results of the efforts made during the last five or six years. While they recognize the good work done by the post-graduate schools at Hammersmith and Tottenham, they are of opinion that it does not supply all that, in their view, is urgently required. The two schools mentioned meet the needs of certain kinds of post-graduates, especially those preparing for promotion examinations, and many of the undergraduate schools also have excellent courses for the higher diplomas and degrees. There is no desire to disturb these activities, although in the matter of giving training in certain special clinical subjects much is to be learnt from Vienna.

But more than this is considered to be desirable; in particular and especially it is thought that medical graduates coming from the Dominions and Colonies, and from the United States of America and other foreign countries, should be able to learn by practical experience the character of London as a centre for clinical and scientific medicine, and, if they so wish, to continue some special line of training on which they have already embarked. The visitor who comes with suitable introductions can usually find what he wants, but it has long been thought that there ought to be a definite organization in London to which any medical practitioner qualified in his own country could apply. The Post-Graduate Medical Association was established, with the help of Sir William Osler and Dr. Hurst, to serve this purpose, and the Fellowship of Medicine was started by Sir StClair Thomson and Sir John MacAlister to collect information as to courses and clinics open to medical visitors, and to promote friendly intercourse between members of the profession in this country and their brethren from overseas. Before very long the two bodies combined, and the efforts then made to meet the needs of the situation are deserving of all praise. Yet it has seemed to many in London that they have not been as successful as might be desired, and that in particular not enough is being done to welcome our brethren from the Dominions and Colonies, and that not in the best way. In consequence several informal meetings have been held during the winter for discussion of the situation and how it can be improved. There is, we gather, general agreement that graduate and undergraduate instruction cannot usefully be given at the same place and at the same time, and evidence of this has been afforded by the fact that the undergraduate schools, which in 1919 had agreed to help the Fellowship, eventually withdrew their offer. At the last but one of the informal meetings to which we have referred Sir Thomas Horder, who was in the chair, undertook to write to teachers in London asking for their opinion as to the possibility of arranging special days on which post-graduates might be received at ward visits reserved

for them, in this way avoiding any disturbance of the opportunities afforded to undergraduates in their routine curriculum. At the last meeting he reported that to seventeen letters he had received sixteen replies, all of them favourable, and all indicating willingness to help, either in this way or by giving demonstrations at some post-graduate centre. In one or two instances all the senior members of the teaching staff of a hospital expressed their sympathy. It was therefore made clear that individual teachers attached to undergraduate schools were available for post-graduate teaching provided the necessary machinery were established. This would appear to be a very important factor in the success of any scheme. It was suggested also that special laboratory opportunities might be arranged in London and in Cambridge. At an informal conference with representatives of the Fellowship of Medicine and Post-Graduate Association the possibility of establishing a hostel was raised, but there are doubts whether this is within the range of practical politics, having regard to financial considerations. The possibility of interesting the British Medical Association, so far at least as to induce it to provide a theatre for clinical lectures and demonstrations and a bureau for information, was mooted.

Meanwhile, it may be said in conclusion that those interested laid particular stress on the international character which it is desired to give to any organization established. By "international" is to be understood not only foreign countries, but the British Dominions and Colonies; indeed, it is hoped that such an organization as is now contemplated may have an imperial character and reflect the Empire ideal.

We note that an informal discussion on post-graduate study will take place at 6 p.m. on Wednesday, March 18th, at the Royal Society of Medicine. It will be open to all members of the medical profession, as well as members of the Fellowship of Medicine from other parts of Great Britain and from overseas.

## THE THYROID GLAND, MANGANESE, AND METABOLISM.

THE arresting results published this week (p. 443) by Dr. Herbert W. Nott bring the value of manganese as a therapeutic agent again into prominence. The efficacy of manganese in the treatment of certain infections—boils, carbuncles, whitlows, lymphangitis, gonorrhoeal infections, tonsillitis, etc.—and certain maladies such as asthma and the toxæmias of pregnancy, was indicated by Mr. J. E. R. McDonagh<sup>1</sup> in 1923. His results excited much interest, and his interpretation of them some controversy; chiefly because of his view that manganese changes the condensation of the protein particles in the plasma into dispersion. Dr. Nott's work in associating the action of manganese with the products of the thyroid gland is of peculiar interest in this connexion, and it will be well to draw attention to certain observations, chiefly from French sources, which appear to have a bearing upon it.

It is now generally agreed that the normal operation of the thyroid apparatus (with which there is an increasing tendency to associate the parathyroid glands) is likely to be deranged in certain acute and chronic infections. The observations of Kottmann and others appear to indicate that thyroid disorder is associated with changes in the state of dispersion of serum

<sup>1</sup> *Proc. Roy. Soc. Med., Dermatological Section*, 1923, vi, pp. 66-70.

colloids. Mr. McDonagh's explanation of the action of manganese has a new interest in the light of these observations.

More attention appears to have been paid to manganese in France than in this country or in America. Hannon, Pétrequin, Lemoine, and others have satisfied themselves that manganese is a potent catalytic agent possessing the property of acting as an intermediary between the tissues and oxygen. It appears to be one of those agents—of which thyroxin, the reputed active principle of the thyroid gland, is another—concerned in regulating the capacity of the tissue cells to utilize oxygen. It is a powerful factor, as is thyroid secretion, in causing regeneration of the blood corpuscles. It may be for this reason that certain French physicians give to manganese so prominent a place in the treatment of such states as anaemia, chlorosis in girls, haemophilia in boys, convalescence from acute maladies, malnutrition, and other conditions in which functional impairment of the thyroid gland is frequent. It would seem that if manganese be so indispensable to the processes of oxidation within the tissue cells, and if, as Kendall states, the function of thyroxin be to regulate the capacity of the cell to utilize oxygen—its rate of functioning being dependent on the physical state of the cell—then the efficacy of thyroxin may be intimately associated with the cell's content of manganese. Dr. Nott's happy combination of thyroid substance and manganese may thus have a physiological basis of much significance; at all events it affords good ground for further investigation.

The distribution of manganese in the animal organism and in foods is of great interest in this connexion. It is found in precisely those situations in which vitamins are found, and it is lost to the body by the same means which lead to the inadequate ingestion of vitamins, and, it may be added, of iodine. Bertrand and his pupils have advanced good evidence for their statement that manganese "is absolutely indispensable to life and is encountered in all living tissues, both vegetable and animal." It is most abundant in those tissues in which physiological processes are most active, as in the liver, the kidneys, the heart, and the mucous membranes. It is present in fruits and in the growing parts of plants, especially in green leafy vegetables. It occurs in wheat and other cereals, being present, like vitamins and iodine, in the outer layers of the grain, and, like them, being removed in the manufacture of white flour. Thus, while wheat bran contains as much as 3.27 mg. of manganese per 100 grams of material, white flour is lacking in it. How significant these observations are will be obvious to all who have followed modern investigations in regard to vitamins. Clearly, then, further study of manganese in relation to the organism in general, and the thyroid gland in particular, is called for. An attempt of this kind has lately been made by Levine and Sohm in America. These observers have found that the administration of small quantities of manganese to rats increased their rate of growth, improved their coats—making the hair longer and more silky—and caused the animals to be more active. Of even more interest are the observations of Camescasse on debilitated children. He found that, despite rest, good country air, sunlight, and regular and copious nourishment, certain children failed to flourish or to increase in weight. Many measures were adopted to improve their metabolism—iron, arsenic, cod-liver oil, preparations of iodine, and general tonics—but without conspicuous success. When, however, minute doses

of manganese were given to these children daily (0.03 to 0.07 gram of manganese dioxide in cachets), within fifteen days striking improvement in weight, in metabolism, and in general appearance resulted in the majority of them (in 9 out of every 10 girls, and in 5 out of every 10 boys). It is of interest to note this difference between girls and boys, since it again suggests some underlying endocrine influence. It is to be noted also that it was unnecessary to do more than recharge the tissues with manganese by a course of fifteen days' treatment; thereafter their weight continued to increase and their general condition to improve.

These observations suggest, as has been said, that Dr. Nott's methods deserve further study both by practising physicians and by laboratory workers.

## FOOD PRESERVATIVES.

We have already mentioned that draft Orders on food preservatives have recently been published by the Ministry of Health, and, in terms in all essential respects identical, by the Secretary for Scotland.<sup>1</sup> They are very much what was expected, for they carry out the recommendations of the Departmental Committee which reported in October last.<sup>2</sup> The Orders would prohibit the use of food preservatives in general, but allow sulphites and benzoates to be used in limited amounts in certain specified articles of food. Certain colouring matters also are prohibited, the most important of which is copper.

In the first place, we welcome the appearance of these Orders as an important advance in public hygiene. The English law regarding food preservatives hitherto has been very lax—indeed, it has been far behind that of most other highly civilized countries—and these regulations introduce necessary reforms long overdue. The almost unrestricted use of food preservatives hitherto allowed in this country has, however, been a convenience to certain trades, and these are naturally objecting to the new proposals.

The appearance of the new Orders was anticipated by a vigorous attack in the columns of the *Times*; this gave rise to a correspondence which included several effective and well reasoned replies. Sir William Pope, who opened the attack, and other critics admitted that some reforms regarding food preservatives were necessary, and confined their attack chiefly to the proposed prohibition of boric acid. The question as to how much damage is done to the consumer by the use of boric acid as a food preservative is a matter of controversy.

It is pretty generally admitted that boric acid may be injurious to infants and invalids, and that some healthy persons are very susceptible to this drug. These facts alone are a sufficient reason for condemning the existing conditions. Hitherto the use of boric acid has been prohibited in milk, and dealers have been required to declare its use in cream, but otherwise no definite restrictions have been placed on its employment, and there has not even been an obligation to declare its presence in food. Sir William Pope and other experts have attacked the proposed prohibition of boric acid on the ground that there is no conclusive evidence that moderate amounts produce harmful effects on normal healthy adults. There is, of course, little likelihood of absolutely conclusive evidence being obtained on this question, since boric acid, like nearly all other substances which have been used as food

<sup>1</sup> BRITISH MEDICAL JOURNAL, February 21st, p. 375.

<sup>2</sup> See BRITISH MEDICAL JOURNAL, November 1st, 1924, pp. 821, 828.

preservatives, does not produce any rapid and obvious harmful effects. Moreover, powerful trade interests are concerned in defending its use, and such interests never lack able expert defenders. As long as trade interests are anxious to maintain the use of boric acid as a preservative there is no likelihood of the evidence against it being universally admitted as satisfactory. Hence we need expect no finality in the dispute as to the pharmacological action of boric acid when used as a food preservative. Our own view is that in such questions the public is entitled to the benefit of the doubt, and that no substance ought to be permitted as a food preservative unless it is certain that it is harmless.

Knowledge regarding the cumulative effects of drugs when these are given daily for years is extremely defective, and we see no reason why the poorer sections of the community should be forced to take unnecessary risks. Other highly urbanized peoples, such as the United States and Germany, manage to feed their populations at a reasonable price without using boric acid, and hence we view with suspicion the statement that prohibition of boric acid will raise the price of food, particularly since this threat has already been both made and disproved in the case of milk. Undoubtedly boric acid can be used as a cheap and convenient substitute for proper care and cleanliness in the preparation of food, but this is not a reason for permitting its use.

We hope the draft regulations will be carried through.

#### THE "ANNALS OF SURGERY."

WITH its January number the *Annals of Surgery* enters upon its eighty-first volume, and at the same time commemorates the forty consecutive years of editorship by Dr. Lewis Stephen Pilcher. He is still editor, but now works in association with Dr. James Taft Pilcher, and has the collaboration in this country of Mr. Sampson Handley. The Lippincott Company is to be warmly congratulated upon the continued success of the undertaking and upon the distinguished list of contributors to this commemorative number. Dr. W. W. Keen, in a short opening paper on the early days of the *Annals*, "when it was not the *Annals of Surgery*," recalls that its starting point was the formation (1878) of the Anatomical and Surgical Club (later Society) of Brooklyn, from which emanated between 1879 and 1884 nine volumes. The first volume—a very thin one, dated 1879—bore the title *Annals of the Anatomical and Surgical Club of Brooklyn*. Later it became *Annals of Anatomy and Surgery*. The first number published under the name now familiar the world over appeared in January, 1885. Dr. Pilcher was the first president of the original society and a contributor to the volumes. In the winter and spring of 1884 he visited Europe. In Germany he became acquainted with Schede, Bergmann, von Langenbeck, Hahn, Hagedorn, and Volkman; and in England he met Lister, James Paget, Timothy Holmes, John Marshall, Lawson Tait, Thomas Keith, John Chiene, William Macewen, C. B. Keetley, and Rickman Godlee. One evening in April, 1884, Keetley was dining with Dr. Pilcher, and the after-dinner talk turned upon the theme of possible future surgical journalism. They speculated upon the value and possibilities of an international surgical journal in which the work of the two nations should be united, but to neither did the idea seem more than a dream. Pilcher had already endeavoured to interest the great medical publishers of New York and Philadelphia in the idea of a journal devoted to surgery, but without success. When he arrived home, however, early in May, he found waiting to see him a gentleman who wished to discuss the feasibility of undertaking

the publication of a journal devoted to surgery. This was James H. Chambers, who had had considerable experience as a publisher of medical journals, and was confident that such a journal of high class would be a business success. The outcome of the discussion was that an agreement was reached and a contract made under which a monthly journal, to be called the *Annals of Surgery*, was to be edited and published. For forty years since that date the journal has continued to appear without intermission. For seven years C. B. Keetley was Pilcher's London collaborator. Keetley, who was surgeon to the West London Hospital, was possessed of great natural ability, with a leaning to orthopaedic surgery, but was much hampered by deafness. Among prominent supporters were Treves, Jacobson, Macewen, and Watson Cheyne, portraits of whom are given. Dr. W. J. Mayo refers to the forty-five years of the American Surgical Association, founded by the historian of American surgery, Samuel D. Gross, as well as to past contributors to the *Annals*—Senn, Murphy, Billings, Parkes, Roswell Park, and others. The connexion with this country, maintained by the collaboration of Mr. Sampson Handley, is emphasized by the inclusion of his portrait. He enters upon his new undertaking with a brilliant communication on lupus in its surgical aspects—furnished with numerous illustrations and observations. Mr. Handley shows that lupus is an infection involving the lymphatics of the skin papillae, and at the same time a rather wider area of the deep lymphatic plexus. By a corrected view of its pathology he proves that excision so as to include the whole of the superficially infected area, together with a slightly larger area of the deep fascia, followed by primary suture, is the treatment to be adopted whenever practicable. Light treatment tends to fail because it does not influence the deep fascial lymphatics. The doctrine of the paper extends beyond the subject of lupus, and has a bearing upon the treatment of rodent ulcer and carcinomas supervening upon lupus scars. Following Mr. Handley are over thirty articles covering the wide field of surgery, ending with one by Royal Whitman on the abduction treatment of fracture of the neck of the femur. The founding of the *British Journal of Surgery*, which has now published a composite index covering ten years, is alluded to by Macewen in a letter, here reproduced in facsimile. Sir Berkeley Moynihan, in contributing a valuable article on acute pancreatitis, shows that British surgeons continue to be warm well-wishers of the *Annals of Surgery*. The BRITISH MEDICAL JOURNAL joins in the congratulations to Dr. Pilcher, well knowing that his editorial work represents but one side of his activities. His *Ex Libris Antiquis*, a list of books of the old masters of medicine and surgery, etc., published in 1918, represents another side. The very success of the *Annals* encouraged emulation, and Dr. Franklin Martin, editor of *Surgery, Gynecology and Obstetrics*, and Dr. Walter Brickner, editor of the *American Journal of Surgery*, add their congratulations.

#### THE LIFE AND DEATH OF CELLS.

THE Japanese Government Institute for Infectious Diseases at the Tokyo Imperial University has recently issued a second volume of its Scientific Reports.<sup>1</sup> It deals with the year 1923, and contains eighteen articles on bacteriology and serology, ten on pathology, and five on chemistry. Most of the papers are printed in English, though a few are in German or other languages. They deal with a variety of subjects: even to give a list of the titles of the articles would occupy a large space, and we must content ourselves by stating that the volume will be placed in the Library of the British Medical Association, so that anyone who wishes

<sup>1</sup> *Scientific Reports from the Government Institute for Infectious Diseases at the Tokyo Imperial University*. For the year 1923. Vol. II. Edited by Dr. Y. Miyagawa. Tokyo: Shirokane-Daimachi, Shibaku. 1924. (Double cr. 8vo, pp. 552; illustrated.)

to refer to experimental work carried out at this institute will know where a copy of the scientific reports is available. There are, however, two or three articles to which we will here call attention, because they suggest a promising method of approach in the study of regeneration and repair of tissues. Dr. Y. Miyagawa has made a study of the biological function of the constituents of dead cells, particularly of the effect of the constituents of red blood corpuscles on the regeneration of red blood cells, of the constituents of the epithelial cells of the kidney on the functions of the kidney, and of the constituents of the liver cells in relation to the secretion of bile. He has come to the conclusion that all the cells of organs and tissues of the body are constantly dying, and that part of their constituents are absorbed into the general circulation and act on homologous cells, promoting their functional activity and performing the important duty of maintaining them in good physiological condition. He holds that two varieties of influences play on all the living cells of the body—that exerted by the nervous system, and that due to direct action brought about by constituents of dead cells absorbed into the general circulation. He calls this latter direct action an “auto-regulation.” This auto-regulation acts directly on homologous cells, and only on these. But it remains to be decided by further research whether or not the substances derived from the constituents of a dead cell really act directly on the living cells or work through the nerve mechanism. The same investigator, in collaboration with three colleagues, has a second article on the influence of the parenteral inoculation of a pulmonary cell suspension into a living animal. Following the injection of a suspension of the parenchymatous cells of the lung into guinea-pigs and rabbits, a remarkable degeneration, and even necrosis, was observed in the lungs of the injected animals; it was associated with serous exudation and partial collapse of the lung. These changes were not inflammatory, but had the character of a true degeneration. Other organs were affected little if at all. The same paper records a good deal of experimental work on the effect of the injection of pneumotoxin. One other paper on a closely related subject has a general interest. Dr. M. Ono set out to discover how many red blood corpuscles perish each day in a healthy individual. Two methods were used for this calculation—the first from the length of life of red corpuscles, and the second from the daily quantity of biliary secretion. It is estimated that the length of life of a red blood corpuscle is about thirty days, and by calculating from the total quantity of red cells circulating in the blood Dr. Ono has worked out that about 500,000 million corpuscles perish each day, a number which corresponds to the loss of about 100 c.cm. of blood. By the second method of analysis, a quantitative estimation of biliary secretion, the author came to much the same conclusion.

#### SHAVING-BRUSHES INFECTED WITH ANTHRAX SPORES.

THE untimely death of Professor Ellermann from using a shaving-brush infected with anthrax spores has led to the publication by the Institute for General Pathology of the University of Copenhagen of an account of the case, and the examination of the brush, by Oluf Thomsen and Vilh. Jensen. Professor Ellermann's illness began on December 17th, 1924, as a small spot on the left cheek. This was followed by much oedema, but without at first any noticeable affection of the general state of health. The brush sent for examination proved to be of a large size model (about 13 cm. long, with handle). It was made to imitate badger, but actually consisted of dyed Chinese horsehair. Bacteriological examination showed that the hairs of the brush were infected with anthrax spores. In spite of the injection of anthrax serum Professor Ellermann died on

December 24th. It will be remembered that the first case of anthrax traced to a shaving-brush occurred in England in 1915. In that year six cases were reported; in 1916 thirteen cases; in 1917 and 1918 none were reported, but there were fourteen in 1919, thirteen in 1920, and four in 1921. No cases have since been observed in England. Consequently, the number of cases observed in the civilian population in England amounts to fifty, with eighteen deaths. Among the troops in Great Britain from December, 1914, to February, 1917, eighteen cases of anthrax were ascertained; of these, four were certainly due to infected shaving-brushes. Among the British troops in France from January, 1915, to February, 1917, there were twenty-eight cases of anthrax, and of these the infected spot was on the cheek, chin, or neck; in no case was it possible to demonstrate that the infection originated from shaving-brushes, but this does not prove that it did not, for shaving-brushes were issued as part of the equipment. In the British Navy, from December, 1919, to January, 1921, there were six cases, and in two of these the infection might certainly be regarded as due to shaving-brushes. A complete account of the cases of infection occurring in England and other countries is given in the article, and it is stated that a considerable number of shaving-brushes made of horsehair from China, but falsely labelled, appeared on the market in 1915. The measures taken by the Ministry of Health are related, and the passage (July, 1919) of the Anthrax Prevention Act, which gave the Government power, by an Order in Council, to forbid the importation of suspected goods, is noted. Such an Order was made prohibiting the importation of shaving-brushes manufactured in Japan, for it was found that infectious brushes were being imported from that country. This, together with the destruction of a large number of shaving-brushes suspected of anthrax infection, appears to have prevented the occurrence of further cases. An interesting point about the case recorded by Thomsen and Jensen is that even where there is reason to suppose that disinfection has been carried out there is no guarantee whatsoever of its efficiency; private disinfection is therefore an additional safeguard. This article, written in excellent English, is published, together with several other articles in English, in *Acta Pathologica et Microbiologica Scandinavica*, vol. i, Fasc. 2, 1924.

#### PATENT MEDICINES.

Dr. J. B. CONES, F.R.S., professor of organic chemistry in the University of Leeds, recently gave an address on “patent medicines” to a meeting of the Norwich Rotary Club. He began by making a quite unnecessary apology for, as a chemist, intruding on the domain of medicine. In the matter of synthetic drugs, to which Dr. Cohen first referred, the medical profession is entirely dependent on the chemist, who has sometimes presented it with drugs of undoubted value, such as, for instance, the arsenobenzol series. The synthetic chemist, Professor Cohen said, produces substances having a definite composition and exerting definite physiological effects; they can be prescribed in doses ascertained by scientific methods. This scientific development of drugs had to compete with the quack nostrum vendor, but on unequal terms, because, whereas the latter advertised, generally in grossly exaggerated terms, the scientific chemist gave his knowledge freely. He recalled how the British Medical Association had published two books—*Secret Remedies* and *More Secret Remedies*—which contained analyses and descriptions of patent medicines and other particulars about them. The revelation was so astonishing that the Government appointed a Select Committee on Patent Medicines in 1914; unfortunately its report was published just before the outbreak of war. The Committee had summarized the situation regarding the sale and advertisement of patent and proprietary remedies

as follows: "For all practical purposes British law is powerless to prevent any person from procuring any drug or making any mixture, whether potent or without any therapeutical activity whatever (so long as it does not contain a scheduled poison), advertising it in any decent terms as a cure for any disease or ailment, recommending it by bogus testimonials, and the invented opinions and facsimile signatures of fictitious physicians, and selling it under any name he chooses, on the payment of a small stamp duty, for any price he can persuade a credulous public to pay." Some patent medicines, Professor Cohen continued, were fraudulent nostrums, dangerous remedies used for improper purposes, or fraudulent preparations used for misleading their victims, such as alleged cures for cancer, consumption, and epilepsy. After dealing in detail with some of the advertised patent medicines, he said that serious injury might be done to the public by misleading prescriptions and excessive claims, yet their sale and advertisement were unrestricted and uncontrolled by law, and so hedged in by legal anomalies that to attempt prosecution for fraud was merely to court failure. He then read out the recommendations of the Committee, which had found that for many secret remedies grossly exaggerated claims of efficacy were made, "causing injury by leading sick people to delay in securing medical treatment; containing in disguise large proportions of alcohol; sold for improper purposes; professing to cure diseases incurable by medication; or essentially and deliberately fraudulent." This class of remedies, the report continued, "contains none which spring from therapeutical or medical knowledge, but they are put upon the market by ignorant persons, and, in many cases, by cunning swindlers, who exploit for their own profit the apparently invincible credulity of the public." This, the Committee concluded, constitutes a grave and widespread public evil. Viscount Astor, when Parliamentary Secretary to the Ministry of Health, prepared a Proprietary Medicines Bill, which was read a second time in the House of Lords. It passed through committee and was reported to the House; this was in July, 1920, but since then nothing has been done. We are, however, glad to note some evidences of an increasing public realization of the evil consequences of this traffic. The discussion by the Publicity Club of London last November (reported in the SUPPLEMENT of November 22nd) is a sign that proprietors of some of these preparations are beginning to realize that their position is open to criticism, and there has recently been gratifying evidence that the newspaper press is becoming alive to its responsibilities.

#### THE HEBREW UNIVERSITY, JERUSALEM.

THE NEW Hebrew University of Jerusalem will be opened by Lord Balfour on April 1st. The Jews have already created in Palestine a network of educational institutions, and with the inauguration of the university the foundations of a complete educational system will have been laid. The purchase of a house on Mount Scopus, built by the late Sir John Gray Hill, had been just effected in 1914, to serve as part of the university, when the outbreak of the war stopped the work for the time being. On July 24th, 1918, the foundation stone of the university buildings was laid, and Professor Geddes and Mr. Mears drew up designs, which were exhibited at the Royal Academy in London. It is proposed that the university shall start as a research centre primarily, with a view to promoting an intellectual atmosphere and the achievement of a very high level of scholarship. The medical department was founded in the spring of 1921, and a research laboratory for microbiology is now almost completed. It is expected that work in this microbiological institute will begin in the late summer of this year. An x-ray, therapeutic, and diagnostic institute has also been equipped,

and the American Jewish Physicians Committee is now engaged in raising funds for the erection of a modern university hospital. As soon as the necessary amount has been collected the committee will begin to erect a medical college, with laboratories for physiology, anatomy, histology, and pathology, lecture rooms, and accommodation for post-graduate instruction and tropical health work. An undergraduate school will slowly evolve. The committee hopes to institute at an early date visiting lectureships in the various branches of medicine and surgery, to be held by the leading medical teachers of Europe and America. A project is under consideration for a chemical institute comprising two departments, one for general chemistry—both synthetic and analytic—and the other for biochemistry. An institute for Jewish studies is planned to be a centre for promoting the knowledge of Hebrew and cognate languages, Jewish literature, history, and philosophy, and also for advanced research and instruction for selected pupils. A Jewish national library is being organized, and there are already 250,000 cards in the catalogue. Many books have been presented by various European Governments, the British Museum, and the New York Public Library. A special medical department of the library was opened in the summer of 1923, and is provisionally housed in the Pasteur Institute. The university will be open to students of all creeds, races, and nationalities.

#### STEEL HOUSES IN LONDON.

A COMMITTEE appointed by the Minister of Health to consider new materials and methods of building for working-class houses has reported on constructions in steel, concrete, timber frame (with external steel plate), and burnt clay block, and it is now proceeding to arrange for domestic architecture in steel to be exhibited for the instruction of the public. On the recommendation of this committee, the Minister of Health has desired the London County Council to arrange for the erection of two small two-story houses having a steel frame or skeleton, after the design of James Wild and Co. (Housing), Limited, of Manchester. A suitable site on one of the Council's housing estates, where the erections can easily be inspected, is likely to be taken for the purpose. The price of erection of these houses, which are to be of the non-parlour type, with three bedrooms, is £435 each, this sum to include the necessary work on drains, paths, and fences. Towards the cost of providing the two houses the Government is prepared to contribute £400, without conditions of any kind, but no further subsidy will be payable, and the houses when erected will be the property of the London County Council. Meanwhile a steel house of another design has been put up, temporarily and for demonstration purposes only, in one of the principal London thoroughfares. This is a one-story dwelling built by the Constellation Company, Limited, on an L.C.C. site in Upper Tooting Road. The house consists of five rooms, the largest measuring 14 ft. by 12 ft., and includes all the appurtenances of kitchen and bathroom. The walls are of galvanized steel laid upon a standardized wooden framework: the treatment of the metal with zinc prevents the rust which would otherwise be inevitable on steel plate, and the sheets are carefully interlocked at the joints so as to make the house weather-proof. An inner and outer sheet of steel are used, each sheet being backed by a layer of felt, and between the two layers is a space of 4 in., which can be left empty or filled with "breeze." All the metal, instead of being left flat as in other steel houses, is stamped in relief so as, with ingenious painting, to resemble externally a rough-cast stone, and internally an oak panelling or a white tiling as desired. Here we have, not the lath painted to look like iron, but the iron, or steel, painted to resemble more usual building constructions, but the result is to give a more

substantial and decorative appearance than might be expected from so uncompromising a material as steel. The gabled roof is of wood, with Somerset tiling, the chimneys and flues are of concrete, the foundation of the house is a concrete raft, above which is a damp-course, and a jointless flooring. The price of the house is £450, or, if the parlour be omitted, £385, allowing for a weekly rental of 15s. or 12s. 6d., including rates and taxes. The house was erected within seven days, and decorated within another seven. The steel-frame house is well known in many parts of the world, especially British Columbia, but it has still to adjust itself to the British climate. On the occasion of the house warming by the Mayor of Wandsworth, the little bungalow, with the daffodils in the front garden, the red tiles on the roof, and the dainty furniture which an enterprising firm had installed, had the appearance of an ideal cottage home. The builders laid stress upon its permanence (claiming for it a life equal to the ninety-nine years of the ordinary lease), its dryness, and the ease with which parts could be replaced or the whole redecorated. They could also claim, of course, that although some people may have a prejudice against being encased in steel, a not inconsiderable and a very healthy portion of the population do in fact live within steel walls already—namely, the officers and men of His Majesty's Navy when serving afloat.

#### EXPERIMENTS ON DOGS.

SIR FREDERICK BANBURY, when in the House of Commons, used to introduce a bill with the title, the Dogs Protection Bill. It was a bill to prohibit any experiment on a dog. It was a hardy annual of varying fortune; once it slipped through the second reading stage, but was eventually rejected by a substantial majority. When its father went to the House of Lords he introduced it there last March; it led to an interesting but one-sided debate, as may be seen by reference to our report of the proceedings (April 5th, 1924, p. 639), for nobody but the mover and his second had a good word to say for it, and Lord Banbury did not think it prudent to go to a division. But it would be imprudent to assume that the last has been heard of it. An article by Dr. Herbert Snow published in the *Nineteenth Century* for January is proof that the antivivisectionists still nurse hopes. His article professed to give reasons why such a bill should be passed. Dr. Snow has been, if we remember right, an antivivisectionist for many years, and his reasons are many years old, and all of them have been shown many years ago to rest on want of acquaintance with the true facts or inability to understand them. Dr. Snow, who has come forward or been put forward as a champion of the antivivisectionists, seems to have befogged himself by much reading of antivivisection "literature" and not verifying his facts. Mr. Stephen Paget, vice-chairman of the Research Defence Society,<sup>1</sup> to whose vigilance and well informed defence of physiology and experimental medicine the profession has long owed a deep debt of gratitude, has made a reply, brief but all the more effective on that account, in the *Nineteenth Century* for March. Mr. Paget takes up a number of the assertions echoed by Dr. Snow, and one by one shows that they are foolish or contrary to the facts, or both. Mr. Paget has unearthed a statement in one of the antivivisection magazines from which it would appear that the antivivisectionists are beginning to pose as martyrs. The writer said, "We and our propaganda are extremely unpopular. We are disliked excessively, I may say loathed." Some of them do not like to be called "antivivisectionists"; but what would they prefer? "Obstructionists" or "obscurantists" would not be sufficiently specific.

#### A MEDICAL STUDENT IN GLASGOW NINETY YEARS AGO.

DR. J. H. ALEXANDER<sup>1</sup> has had the happy idea of publishing some notes of his father's student days in Glasgow in the early thirties, when memories of the Napoleonic wars were still the subject of much reminiscent conversation. Early in his career (1832), as a follower of Hippocrates, he had the experience of watching the invasion of Glasgow by cholera, and of the first death, in a flat above that in which he lodged. The Medical Board exerted itself to stay the plague by fumigating the infected houses, by preventing anyone from entering or leaving towns or villages if it was known that he or she came from an infected district, and by offering senior students a guinea and a half a week to attend cholera patients. But in spite of all the well meant efforts the mortality was such that in some towns carts went round during the night to collect the dead, some in coffins, others without; the corpses were buried in trenches, often in land outside the graveyards; the conditions thus resembled those so vividly described by Walter G. Bell in his account of the great plague of London. The anatomical rooms were in those days largely dependent for supplies upon the body-snatchers, as graphically described by Robert Louis Stevenson's story in *Tales and Fantasies*. William Alexander's account of the activities of the resurrectionists in 1833—which was after the execution of Burke (1829) for murders with the object of supplying anatomical subjects—describes how the exhumed corpse in a sack was placed upright in a gig between the two resurrectionists and driven off from the rifled grave. As much as £12 to £14 was paid for a body, but the risks were not slight, for the relatives of the deceased would lie concealed in the churchyard night after night with arms, fully determined to resist even to bloodshed. He tells the story of a student who, on returning to Glasgow after the Christmas holidays, found his dead sister laid out on one of the dissecting-room tables. The account of operations without anaesthetics and antiseptic or aseptic precautions is enough to make the reader thankful that he did not live in "the good old times."

#### THE HOME AMBULANCE SERVICE.

SHORTLY after the armistice a number of motor ambulances which had been maintained in Northern France by the British Red Cross Society and the Order of St. John were liberated, and the two bodies appointed a Home Service Ambulance Committee, which worked out a scheme for stationing ambulances at convenient points throughout England and Wales and Ireland, so that one should always be available for accidents or for the removal of sick persons or convalescents to hospitals or to their own homes. The scheme met with very general approval, and the ideal put before the committee has now nearly been attained. At the end of last year it had 342 ambulance stations in the country and 33 affiliated stations, making a total of 375. The number of stations in the various counties varies according to local needs, and the number of patients carried varies also: thus, in West Lancashire, with 11 ambulances in service, 63,000 patients have been moved; in the West Riding, with 14, over 21,000; in Durham, also with 14, nearly 16,000; and in Essex, with 15, about the same number. In the agricultural counties the number of patients moved has, of course, been smaller; thus, in Kent, with 16 ambulances, 7,300 patients were handled, and in Cornwall, with 6 ambulances, about 1,900. As a rule the ambulances are controlled by the county director, but in Wales special arrangements are being made. In Southern Ireland the scheme has not been developed to the extent desired, but in Northern Ireland, with 14 ambulances, nearly 9,000 patients have been moved. Since the Home Ambu-

<sup>1</sup> The annual subscription to the Research Defence Society is 10s. It publishes a quarterly periodical with the title *The Fight against Disease* (price 6d.). Its offices are at 11, Chandos Street, Cavendish Square, London, W.1.

<sup>2</sup> *Glasgow Med. Journ.*, 1925, ciii, 37-44

lance Service was instituted municipal bodies have shown a greater tendency to set up ambulance services of their own, but in many cases they have preferred to depend on the Home Service Committee for the control of this work. Thus, the city of Plymouth has delegated the whole of its ambulance transport work, including the carriage of crippled children to special schools, to the Plymouth centre of the St. John Ambulance Association, which works in association with the Plymouth division of the British Red Cross. A private telephone line connects the central police with the ambulance stations, which are also included in the borough fire alarm installation, so that the ambulance is called simultaneously with the firemen, and a car follows each fire engine. At Bolton in West Lancashire the ambulances, working under a joint committee and staffed by members of the brigade, carried nearly 17,000 cases during 1924, and here again the work done includes much for the public health authorities and also for the education authority in connexion with crippled children. Whatever service is eventually set up, it must depend for its efficiency on the co-operation of trained attendants, and the Home Ambulance Committee aims at bringing all its ambulances into the charge of units of the order or society. Already the system has brought many recruits, so that it has promoted and encouraged the acquisition of skill in first-aid treatment. There is a vastly greater incentive to go through a course of first-aid training when the student knows that his skill will be put to constant use in connexion with the ambulances than if he may only be called upon to exercise it occasionally and at long intervals.

#### THE BRITISH ASSOCIATION MEETING, 1925.

ARRANGEMENTS are well on the way to completion for the next annual meeting of the British Association, which takes place at Southampton from August 26th to September 2nd; the programmes will be issued shortly. The President is Dr. Horace Lamb, F.R.S., the author of many papers on mathematical physics, and formerly professor of mathematics in the Universities of Adelaide and Manchester. The sections number thirteen, and the presidents of four of them are as follows: physiology, Professor A. V. Hill, F.R.S., of University College, London; psychology, Professor C. E. Spearman, F.R.S., also of University College; anthropology, Dr. Thomas Ashby, director of the British School of Archaeology at Rome; and education, Dr. W. W. Vaughan, head master of Rugby. The proceedings will include a number of joint discussions between different sections. The sections of zoology and physiology will unite for a discussion on the functional significance of size; those of psychology and education, on recent investigations upon functional guidance; and those of physiology and psychology, on the acquisition of muscular skill. Other discussions set down are on health in schools, the disciplinary value of subjects, the training of teachers, and the teaching of biology.

#### CONGRESS OF RADIOLOGY.

It has now been decided that the Congress of Radiology in London shall begin on Tuesday, June 30th, with a reception, and that the formal opening shall take place on the following morning, July 1st. Sessions will be held on each of the following days until Saturday, July 4th, when the congress will come to an end, but in the following week visits will be paid to other centres of interest. During the congress an exhibition of radiological and electrical apparatus will be held, and there will also be an exhibition of radiograms, in which dental radiograms will be included. The congress is described as a preliminary meeting of international congresses of radiology, and it is intended that arrangements for the first international congress, its

date, and the country in which it should be held, will be decided by an international committee during the meeting in London. Electrotherapeutics and allied subjects will be included within the scope of the congress, and radiological and electrotherapeutic societies are invited to send representatives to serve on the international committee. The congress in London will be of an international character, inasmuch as radiologists from every country are invited to take part. The fee for membership is £2 2s. The object of the congress is to bring together radiologists from all parts of the world. Papers may be read in the language selected by the author, but it is desired that they should be approved by a recognized society of which the author is a member. It is also asked that a short abstract shall be provided, and English translations of all documents "will be much appreciated." The president of the congress is Mr. G. Thurstan Holland, Ch.M., of Liverpool. The chairman of the organizing committee is Dr. Robert Knox, and the secretary-general is Dr. Stanley Melville. The headquarters of the congress are at the British Institute of Radiology, 32, Welbeck Street, London, W.1. The secretaries, addressed there, will be glad to supply full particulars.

#### INFLUENZA.

LAST week the number of deaths in the great towns of England and Wales was almost the same as in the previous week—352, against 354; in London the number decreased from 92 to 88. Four cities or towns other than London had 10 or more deaths—namely, Stoke-on-Trent (10), Manchester (16), Leeds (13), Stockton-on-Tees (11). Two had 8 each—Birmingham and Preston; one 7—Bradford; four 6—Nottingham, Hastings, Liverpool, and Sunderland. The notifications of pneumonia have also decreased—from 1,742 to 1,473; only in the North and in Wales was there any increase. It appears, then, that the wave of influenza is at or near its maximum. If so, this recrudescence is definitely less severe than that of last year, although the total number of cases has probably been very large. The King, we are glad to note, has been able to leave his bed, and may now be considered convalescent.

THE KING has appointed Dr. John M. Cowan, physician to the Royal Infirmary, Glasgow, to be one of the Honorary Physicians to His Majesty in Scotland, in the room of Sir James Mackenzie, F.R.S., deceased.

At the social evening at the Royal Society of Medicine on Monday, March 16th, the guests will be received by the President, Sir StClair Thomson, at 8.30 p.m. The library will be open and various objects will be exhibited. At 9.30 Dr. H. C. Cameron will give an address on "John Locke, the philosopher (1690), on the upbringing of children." No cards of admission are required, and Fellows are invited to bring friends.

THE first award of the Sir Robert Jones Medal and British Orthopaedic Association Prize of £50 has been made to Mr. G. Perkins, F.R.C.S., assistant surgeon to the Royal National Orthopaedic Hospital, for his essay on "The diagnosis, treatment, and end-results of tuberculous disease of the hip-joint." The subject of the essay for 1925 is "The classification and differential diagnosis of the different forms of arthritis." Essays, which must be submitted by December 31st, 1925, should be sent to the Honorary Secretary of the British Orthopaedic Association, Mr. R. C. Elmslie, M.S., 1A, Portland Place, London, W.1.

WE regret to announce the death of Dr. J. J. Graham Brown, a former President of the Royal College of Physicians of Edinburgh, and consulting physician to the Royal Infirmary, Edinburgh.

## PARALYSIS AGITANS AND POST-ENCEPHALITIC CONDITIONS.

### PROFESSOR CRUCHET'S LECTURE.

UNDER the auspices of the University of London, at the Royal Society of Medicine, on February 25th, with Sir James Purves-Stewart in the chair, Professor René Cruchet of the University of Bordeaux gave a lecture on the relation of paralysis agitans to the Parkinsonian syndrome of epidemic encephalitis.

Sir JAMES PURVES-STEWART referred to the closer and more appreciative understanding between English and French physicians which had grown up since the war. It would be interesting, he said, to listen to a lecture by such a distinguished French physician on a malady such as Parkinson's disease, which was so essentially English.

Professor CRUCHET began by explaining how in 1917, when he described what he believed to be a new disease under the name of "subacute encephalo-mylitis," which later became "encephalitis lethargica," he observed in several cases that an immobile face existed from the onset of the disease, and that this Parkinsonian appearance was, however, quite different from Parkinson's disease. Later, with the opportunities afforded by the epidemic of 1919-20, these Parkinsonian symptoms of encephalitis lethargica became much more common, but they were still to be differentiated from true paralysis agitans. Confusion between these two diseases, however, was very evident owing to the fact that they had certain symptoms in common. Such symptoms had been isolated by Professor Cruchet under the term "bradykinetic syndrome."

### The Bradykinetic Syndrome.

This syndrome, he said, consists essentially of slowness of movement; this is associated with immobility, fixed attitude, kinesia paradoxa, and, according to some writers, muscular resistance. The immobility is most strikingly shown in the expression of the face—the so-called "Parkinsonian mask," not, however, described by Parkinson. This immobility is also shown by the absence of many other characteristic little movements which constitute individuality. The fixed attitude generally consists of a bending forward of the body with a neck shrunk between the shoulders and arms slightly flexed with the hands brought towards the abdomen. Slowness of movements is especially striking on the face: emotional expressions lack spontaneity. Even the movements which have become automatic by habit become stiff and slackened. This slowness is strikingly shown in certain occupations where patients take four or five times the usual number of hours to do a piece of work. This slowness of movement is quite different from that seen in people who are slow from birth or by temperament, in that it is stiff and lacks spontaneity. The movements are, however, perfectly co-ordinated. The more a certain act goes on or is repeated the slower it becomes until it finally stops. Paradoxical kinesia, as described by Souques in 1921, is shown by certain patients who, only able to walk slowly and with difficulty, sometimes find themselves able to run for a brief period of time. This sign, occurring in paralysis agitans, was recognized by Parkinson. With regard to muscular resistance, Professor Cruchet thought that the rigid appearance of patients with the bradykinetic syndrome had given rise to a preconceived idea of muscular resistance, and even of hypertonus. This he believed was by no means essential to paralysis agitans he had never found true rigidity occur. The bradykinetic syndrome was common to a certain number of morbid states and, in addition to the two diseases here discussed, could be found in progressive lenticular degeneration, in disseminated sclerosis and pseudo-sclerosis, dementia praecox, and it might even become spasmodic, as described by Professor Cruchet in 1906, in certain forms of spasmodic torticollis. In Parkinson's disease, he said, the bradykinetic syndrome is present, but strangely enough Parkinson did not mention the peculiar immobility of the face which occurs, perhaps because it was such an obvious phenomenon. Parkinson was more concerned with the difference of his disease from ordinary paralysis, where the onset is sudden,

and with two striking features—namely, the shaking and the bending forward of the trunk. The latter has been shown to be characteristic of the bradykinetic syndrome. Parkinson's description of the patients who were "irresistibly impelled to take much quicker and shorter steps, and thereby to adopt unwillingly a running pace," was that of kinesia paradoxa. The tremor particularly attracted the attention of Parkinson; it appears very early in the disease and is often very violent in the later stages. Subsequent writers added the description of "pill-rolling" to some of these movements. Parkinsonian bradykinesia is therefore characterized by its insidious onset at an advanced age, its progressive evolution, its irritable mental state, and the peculiar shaking which exists at rest and disappears in voluntary action.

### Post-encephalitic Bradykinesia.

The bradykinesia of the post-encephalitic state (Professor Cruchet continued) is quite complete, although the fixed attitudes adopted are more complex and varied in nature than in Parkinson's disease. Slowness of movement has been carefully studied; it is shown in a very interesting manner if the patient reads aloud. Sudden stops occur at the end of the lines, and later between words and even in the middle of words, until stops become more and more frequent, the voice becomes imperceptible, and a total cessation of reading occurs. Similar stoppages occur in the habitual movements of eating, dressing, brushing the hair, etc. Paradoxical kinesia is strikingly shown in the post-encephalitic state. Patients quite immobile and infirm will rise from the chair in his (Professor Cruchet's) consulting room and begin to dance! Other patients are able to do gymnastic exercises and throw quoits in a skilful manner. Similar occurrences have been described by Arthur J. Hall, who recorded the case of a man who drove a lorry from Sheffield to London and back, and by G. L. Thornton. As indicated previously, no true rigidity exists, as these paradoxical movements prove. In addition to the bradykinetic syndrome certain other symptoms occur which enable post-encephalitic conditions to be marked off from paralysis agitans. Tremor is rare, and in only three cases out of a series of a hundred was it of the true Parkinsonian variety. In other cases it did not occur at rest, but only periodically in certain positions of the limbs, sometimes increasing in intensity as a result of violent exertion. Tremor, when it does occur, does not become progressively worse. The mental state of the post-encephalitic patient is calm and peaceful, although he may be afraid of the slightest movement and prefer to remain in bed. The intellectual state is often slackened, but ideas are clear, judgement intact, memory conserved, and reasoning lucid. This has been called bradypsychia or bradypraxis by Verger and Hesnard. As a result of this "slowness of intellect" patients seem to have taken on a new personality. The onset of post-encephalitic bradykinesia is usually definite, and not vague as in paralysis agitans. Somnolence, diplopia, infectious symptoms like those of influenza, and toxic symptoms are often definite. The knowledge of the epidemic nature of the disease is also important. The age of the patient is important: in paralysis agitans the average age is about 60, while post-encephalitic conditions are commoner in young people, and children are frequently attacked. The course of the two diseases is different: post-encephalitic conditions can get better and even be cured, especially in the early forms. Late forms appearing between six months and two years after the initial attack have a less favourable prognosis, although cases have recovered from advanced phases of the disease. Other differential signs include salivation, early in encephalitis and late in Parkinson's disease, while pupil changes in the former and various changes in the cerebro-spinal fluid, especially an increase in

Curious torsion spasms occur also in these conditions, patients sometimes twisting themselves into incredible attitudes; these are analogous to the torsion spasms described by various authors in 1910 and 1911, and of the same clinical family as Wilson's disease. Professor Cruchet considers the curious spasmodic torticollis cases described by him in 1906 to be of the same nature.

These cases show athetotic and choreiform movements at rest, slowness of all the voluntary acts, a fixed attitude, and certain vasomotor disturbances. Epidemic encephalitis has greatly increased the number of these bradykinetic forms, and their spasmodic nature seems to be a secondary phenomenon. Such associated forms have greatly complicated the already diverse picture presented by encephalitis lethargica. Professor Cruchot concluded by indicating that since the action of the virus of encephalitis in the nervous system is very diffuse, certain cases of the true Parkinsonian type did occur; but this was rare, and from clinical observation it was possible, in the majority of cases, to distinguish between the two diseases. Although the anatomical findings were interesting, the clinical distinction was the more important one for the physician.

At the close of the lecture numerous slides were shown: these consisted of photographs of patients and microphotographs of sections of brain. Various microscopic slides were also exhibited.

## Scotland.

### ROYAL MENTAL HOSPITAL, MORNINGSIDE, EDINBURGH.

#### PROFESSOR ROBERTSON'S ANNUAL REPORT.

The one hundred and twelfth annual report of the Royal Mental Hospital, Edinburgh, for the year 1924 was presented by Professor George M. Robertson, physician-superintendent of the institution, at the annual meeting in the City Chambers, Edinburgh, on February 23rd, when the Lord Provost, Sir William Sleigh, was in the chair. It was reported that 212 patients had been admitted during 1924; including 804 on the register at January 1st, 1924, the total number of cases treated during the year was 1,016. The patients discharged recovered numbered 48 and those unrecovered 84. The number of patients who died was 55, yielding the lowest death rate yet recorded in the history of the institution. With regard to causation, there appeared to be a falling off in cases due to alcoholic excess; only 5 were definitely diagnosed as cases of alcoholic insanity, while the amount of insanity attributable in part to alcoholic excess was 7 per cent. for men and 0.8 per cent. for women, or a total of 3.3 per cent. for both sexes. This showed a marked diminution as compared with the corresponding figures for the seven years before the war, which were respectively 16.4 per cent., 9 per cent., and 12.6 per cent. Influenza seemed to be reappearing as a cause, 6 cases having been attributed to this disease.

#### Mental Nursing Homes.

Professor Robertson recalled that when the Royal Hospital at Morningside was opened in 1813 it admitted private patients only, and that it now again relied for its prosperity on the admission of this type of patient. Since Craighouse was added to the institution thirty years ago there had been an ever-growing need for expansion. The public had become more and more averse to sending persons suffering from recoverable or mild attacks of mental disorder into mental hospitals, and the managers had given careful thought to the particular form which any new accommodation should take. Seven years ago they decided to establish, quite detached from the mental hospital, nursing homes in which patients suffering from the early stages and curable forms of mental disorder might receive suitable treatment in the expectation that they might recover without being certified or entering a mental hospital. The scheme, initiated in a small way seven years ago, was now fully established. During the whole of last year four fully equipped nursing homes, accommodating about fifty patients, had been in successful operation in the suburbs of Edinburgh, and then a mansion-house in the country for convalescent patients, which accommodated a dozen or more. Recently the managers had purchased Vogrie House, together with 250 acres of land, some distance outside Edinburgh, and in this large building they con-

templated further developments of the scheme. In these homes the family physician could treat his own patients exactly as he did in nursing homes for other diseases. The managers merely provided the appropriately equipped home and the necessary staff under the direction of an experienced matron. In this way early and mild cases of nervous breakdown could receive appropriate nursing and care. These homes were also useful for patients suffering from the mental breakdown that often accompanied old age; such cases were frequently very difficult to care for at home, yet no one liked to send an aged parent or relative in this condition to a mental hospital. The number of patients admitted into these homes during the year 1924 was 111, and the total number treated in them was 145. Professor Robertson mentioned that two matters connected with such homes should not be lost sight of. One was that such homes should start under disinterested management and only under the aegis of bodies who had already had some experience of the provision needed; the other was that such homes must be under the supervision of the department which keeps under observation places for the treatment of patients in an analogous condition—namely, the General Board of Control. Unless this were done he felt that scandals might arise from the adoption of inefficient methods and from the possibility of injustice to certain patients. The necessary supervision need not be obtrusive to be efficient.

#### Voluntary Admission to Mental Hospitals.

The subject of voluntary admission had developed during the last ten years, but mainly during the last five, and it had indeed grown in Scotland into such favour and to such proportions as to amount to a revolution in the practice with regard to mental diseases. The change was initiated by a simple alteration of the existing procedure introduced into the Act of 1913. Previously the sanction of one of the Commissioners had to be obtained before a voluntary patient could be admitted to a mental hospital. The time required to obtain this sanction caused delay, which was both inconvenient and dangerous, and the Act of 1913 gave authority to the medical superintendent to admit the patient at once upon a simple application made directly to himself. The ease, convenience, and promptitude of this procedure had proved so attractive that the admissions of voluntary patients into mental hospitals in Scotland rose from 112 in 1913 to 181 in 1914 and to 263 in 1919; during the quinquennium 1919 to 1923 the total admissions of voluntary patients had amounted to 1,672. In consequence of this it was now found that 40 per cent. of all the private patients entering mental hospitals in Scotland did so as voluntary patients, and that this percentage was increasing every year. This method formed an ideal alternative to certification, and it was not straining language to call this development a revolution of most happy character, and one that was desired by the public. If to the number of voluntary admissions were added the cases placed in the Royal Hospital at Morningside under the authority of a medical certificate of emergency, it would be found that no less than 95 per cent. of all the cases were admitted without a judicial order. It therefore appeared that the abolition of judicial orders was not so revolutionary a step as it would seem, for no harm appeared to have resulted from the absence of an order in the cases mentioned. A hardship existed in relation to the admission of voluntary patients into certain kinds of mental hospitals in that the Government grant-in-aid of £7 9s. 6d. a head, which was given to parishes towards the support of certified patients, was withheld from the support of voluntary patients belonging to a parish. Certain parishes, however, notably in Argyllshire, and recently the Edinburgh Parish Council, had decided that the poor should enjoy in future the advantages of voluntary treatment, notwithstanding that this involved relinquishing the grant-in-aid.

#### Early Treatment.

An important consideration which attached to these two noteworthy developments that had sprung into existence during the last five or ten years was the possibility of earlier treatment. The nursing home offered early treat-

ment to those with ample means, but it did not meet the requirements of those with modest incomes and of the poor. For them, however, early treatment without the hardship of certification could be obtained as voluntary patients in mental hospitals. Professor Robertson expressed the opinion that by avoiding certification and compulsory detention and by great extension of the system of voluntary treatment, especially by placing it within the reach of the poor, a complete change of sentiment towards mental hospitals would in time develop. At present the law, according to modern ideals, provided a Procrustean bed. It was very disconcerting to the medical man who had faithfully carried out the requirements of the lunacy law in accordance with the time-honoured interpretation placed upon it by a Government department like the Board of Control, to find that he might still be mulcted in heavy damages in a court of law.

#### *The Prevention of Mental Disorders.*

Associated with early treatment was the modern medical ideal of prevention, and the most important step that could be taken in this direction was to find the causes of mental disorder. These were no doubt numerous, but it was not likely that any of them would stare us in the face by their obtrusive activity. It was much more likely that their action was subtle, indirect, and prolonged; a good example of what was required was the insight now possessed into the causation of cretinism, which was a form of mental defect. The absence of minute quantities of iodine, which came mainly from the sea, in the food and drink, and which was prepared for the body in the secretion of the thyroid gland, was the cause. The cause was infinitesimal, its action was insidious, and it operated through the agency of a gland, yet its effects on the mind were very marked. The far-reaching effects of the absence of vitamins in other deficiency diseases and the absence of sunlight were similar causative factors in several diseases. In this connexion Professor Robertson mentioned that four cases of pellagra had been under treatment in the Royal Mental Hospital last year. In one instance the patient had been already suffering from delusions following upon experiments in spiritualism, and during the summer the skin eruption characteristic of the disease had developed. For a long time this patient had, in consequence of delusions regarding food, been upon the verge of starvation, and there was strong evidence that the absence of some essential food constituent, or some disorder of digestion preventing the assimilation of an essential constituent of food, was the cause of her mental disease.

Much attention had been directed to the important results obtained from the treatment of general paralysis with malarial infection. Whereas the expectation of life of sufferers from this disease was usually about three years, many patients were now alive and some had been so much improved as to be discharged and resume their duties, who, had it not been for the treatment by malarial infection, would almost certainly have been dead. It was necessary, however, that the general paralysis should be recognized by the general practitioner at an earlier stage if the patient was to get the fullest benefit from the malarial treatment. How malaria acted was still a mystery, but the view at present held was that the high fever produced by the malaria (104° F.) destroyed the organisms that caused the general paralysis. It was possible that the same results might be obtained by other fevers such as influenza, or even repeated hot baths. The question of treatment by mental suggestion had also been studied in the Royal Mental Hospital, and another important field for investigation was the critical analysis of the fantasies which various patients showed.

#### *Improvements in Buildings.*

Important structural alterations were now approaching completion in West House. These involved improved sanitary arrangements, a complete new system of central heating, hot-water supply, electric lighting, lifts, telephones, and fire alarms, together with redecoration of the institution.

#### EDINBURGH CLINICAL MEETING AND DINNER.

The winter clinical meeting organized by the Edinburgh Branch of the British Medical Association was held on February 27th in the Royal Infirmary, Edinburgh, and proved to be one of the best of its kind that have ever been arranged. The programme drawn up by Mr. F. E. Jardine was excellent throughout. The museum, arranged in the pathological department, was open from 10 a.m. to 6 p.m.; the specimens covered a wide range of interest. In the dietetic department of the Royal Infirmary there was a demonstration of foods showing the calorie value of prepared dishes. In the morning a number of demonstrations of a practical kind were given in the various departments, and the afternoon was given up to an organized clinical demonstration with Dr. Robert Thin (president of the Branch) in the chair. The audience, comprising members and a limited number of senior students, filled the large surgical theatre.

The dinner held that evening in the Caledonian Station Hotel, with the president of the Branch in the chair, was attended by 45. The guests included Sir Robert Philip; Mr. Alexander Miles; Colonel St. C. Thom, medical superintendent, Royal Infirmary; Professor Lorrain Smith, Dean of the Medical Faculty; Dr. J. R. Drever, Scottish Medical Secretary, British Medical Association; Dr. W. T. Blakely, president Glasgow and West of Scotland Branch; Dr. J. A. Hume, honorary secretary Perth Branch; Dr. E. E. Dyer, honorary secretary Stirling Branch; Dr. G. F. Whyte, Dundee Branch; Dr. D. G. Anderson, president Edinburgh Royal Medical Society; Dr. Colquhoun, president of the University Union; and Dr. Tingley, representing the resident staff of the Royal Infirmary. The toast of the British Medical Association was proposed by Sir Robert Philip, and responded to by Dr. Drever; that of the Edinburgh Medical School by Dr. W. T. Blakely, and responded to by Mr. Miles. The health of the guests was proposed by Professor George M. Robertson, and responded to by Professor Lorrain Smith and Dr. D. G. Anderson. The President's health was proposed by Dr. J. V. Paterson and acknowledged by Dr. Thin. The toasts were interspersed with an excellent programme of music contributed by members present. A very enjoyable evening was spent.

#### CLINICAL RESEARCH AT ST. ANDREWS.

During the month of June a post-graduate course will be conducted by the staff of the James Mackenzie Institute for Clinical Research at St. Andrews. The ideals and methods of the institute will be described, and clinical lecture demonstrations will be given on such subjects as the mechanism and significance of cardiac irregularities, the meaning of abdominal pain, suspected tuberculosis in children, and case-taking in general practice. Lantern lectures on ophthalmic subjects will be delivered. Professor Waterston will lecture on the structure and development of the heart from the functional standpoint, and also on the innervation of muscle. Physiological lectures will be given by Professor Herring, and Dr. N. MacLellan will deal with clinical pathology. Dr. Hynd will deal with chemical examination of the urine and blood analysis, including the estimation of blood sugar. Clinical lectures will be given at the Royal Infirmary, Dundee, and the radiological section will include the interpretation of radiograms, and consideration of the chest of the normal infant. Further information may be obtained from the Secretary of the Institute, St. Andrews, Fife.

#### GLASGOW STUDENTS' SUPPORT OF HOSPITALS.

A meeting of the Executive Committee of the Students' Representative Council of Glasgow University was held on February 25th, when the proceeds of the Students' Charities Day, held on January 19th last, were allocated. The sum available for distribution was £7,148, and it was agreed as a general principle that part of the proceeds should be used for the endowment of beds in certain of the larger hospitals. Two years ago beds were endowed in the Royal and Western Infirmaries, and it was agreed that out of the amount available this year £1,600 should be allocated each to the Victoria Infirmary and the Royal Hospital for Sick Children, for the endowment of beds.

Other sums allocated were: Glasgow Royal Infirmary £600, Glasgow Western Infirmary £600, Glasgow Royal Maternity Hospital £300, the Ear, Nose, and Throat Hospital £300, the Royal Samaritan Hospital £250, the Eye Infirmary £100, and similar sums to four other medical institutions.

#### GLASGOW WESTERN INFIRMARY.

The annual report of the Glasgow Western Infirmary for 1924, which is the jubilee year of the institution, shows that during the year 9,871 cases were admitted to the wards, and 35,809 were treated in the out-patient department. The training school for nurses, the school of massage, and the x-ray and electrical department were all reported as being carried on with success. One ward was endowed during the year with a sum of £40,000 received from the trustees of the late Mr. John Ross, Bearsden. With regard to the proposed biochemical department, a donation of £5,000 has been received, but progress is delayed as this department would involve an expenditure of about £25,000, for which further donations are solicited. With regard to finance, there is a deficit of £10,937 in the ordinary income, but, after providing for this out of extraordinary income, and for £19,399 of extraordinary expenditure, there is still a surplus of £64,433, which has been carried to capital. Together with a balance from the previous year there is now available an unrestricted capital sum of £124,329. It is pointed out that the deficit in ordinary income of £10,937 is the smallest that has had to be recorded since 1906, and that the ordinary expenditure is still steadily decreasing.

#### GLASGOW ASSOCIATION FOR THE RELIEF OF INCURABLES.

At the fiftieth annual meeting of the Association for the Relief of Incurables in Glasgow and the West of Scotland Lord Provost Montgomery, who presided, said that the association had been founded in 1874 and the home at Broomhill had been opened in 1876 with 39 patients; it was eloquent of the progress of the home that last year 330 patients had been under its care. Amongst those in the home at the close of last year were two women, of whom one had been admitted as a schoolgirl in 1877, while the other, admitted in middle life, was now aged 91 years. This indicated the care and attention bestowed on the patients and the great burden from which relatives were relieved by their admission. The income last year was more than in the previous year, while the expenditure was less, and the subscriptions from employees of works, etc., had increased.

#### CENTRAL MIDWIVES BOARD FOR SCOTLAND.

The examination of the Board, held simultaneously in Edinburgh, Glasgow, Dundee, and Aberdeen, has recently concluded. Out of 123 candidates 115 passed. Of the successful candidates 24 were trained at the Royal Maternity Hospital, Edinburgh; 34 at the Royal Maternity Hospital, Glasgow; 6 at the Maternity Hospital, Aberdeen; 11 at the Maternity Hospital, Dundee; 10 at the Queen Victoria Jubilee Institute, Edinburgh; 10 at the Cottage Nurses' Training Home, Govan, Glasgow; and the remainder at various recognized institutions.

## England and Wales.

#### DISTRICT NURSING IN LONDON.

THE tenth annual report of the Central Council for District Nursing in London describes the activities of the council during the year ending December 31st, 1924. The gaps in the District Nursing Service of the counties of London and Middlesex received special attention from the council's executive committee, which has been able to arrange for extensions into large and needy areas on the outskirts of London. Such large populations as those of Willesden and Tottenham were particularly difficult to deal with owing to the small number of persons of leisure able to render practical assistance. The Southgate Association has been extended, a new association has been established at Hanwell, and the Harringay division of Hornsey has

been taken over by the North London District Nursing Association. Grants have been made to these districts and promised to Tottenham and Willesden, where it is hoped that associations will be started before long. Towards the end of the year under review careful consideration was given to the particulars required from various nursing associations in connexion with the allocation of these grants, and an attempt has been made to prepare a uniform schedule so that the costs of the service may be readily ascertained, and also the nature and extent of co-operation with public authorities. During the year the committee decided to distribute £1,800 from funds in hand. The trustees of the London Parochial Charities entrusted the council with £2,000 for distribution and £300 for administrative work; they also gave £500 primarily for the extension and establishment of district nursing in Greater London. The sum of £617 12s. 2d. was paid to the council by the Ministry of Health in respect of midwifery and maternity nursing arranged by certain associations. Contributions were also received from the Clothworkers' and Grocers' Companies and the Society of Apothecaries. The representatives of the British Medical Association on the Central Council are Mr. E. B. Turner, Dr. T. W. H. Garstang, and Dr. William Paterson.

#### PONTEFRAC INFIRMARY.

The new wing of Pontefract Infirmary was opened by Princess Mary, Viscountess Lascelles, on February 26th. The new building had been originally intended as a memorial to the late King Edward, and tenders for its construction had already been received when the outbreak of war compelled postponement of the undertaking. The original estimate of the cost was £6,000, but the actual expenditure had exceeded £12,000, which had, however, already been raised. A further fund, inaugurated by the Mayor, had provided £1,200. The accommodation of the institute had been thus increased from fifteen beds to forty. The president, Major C. G. Lyon, in welcoming Princess Mary, remarked that Lord Lascelles's grandfather, the fourth Earl of Harewood, was a vice-president of the original institution when it was opened in 1812. Sir Berkeley Moynihan, in a short address, moved a vote of thanks to the Princess, which was adopted with applause.

#### NORTH OF ENGLAND CHILDREN'S SANATORIUM, SOUTHPORT.

At the annual meeting of the North of England Children's Sanatorium, Southport, on February 21st, it was reported that the number of children admitted during 1924 was 1,262, the average duration of their stay being thirty days. The children mostly came from industrial areas, and were suffering from such diseases as chorea, bronchitis, rheumatism, anaemia and debility after fevers and operations. Dr. H. Blumberg, presenting the medical officer's report, remarked that the sanatorium still received a number of patients more or less crippled from infancy, in whom deformity of the limbs had become chronic, and fixation was of little benefit. He regretted that there were not better orthopaedic facilities in the large towns, so that these deformities could be rectified by early and appropriate treatment. Except on one or two occasions, when the admission of patients was suspended owing to outbreaks of infectious diseases, the sanatorium had been continuously full during the year, and for considerable periods there had been a long waiting list. As the result of a ballot organized early in 1924, a sum of £1,741 had been presented to the sanatorium funds, and, apart from this, the income of the institution had increased from £4,717 to £5,253, of which £3,938 represented receipts from patients, an increase of £766 over the previous year. The deficit on the year's working amounted to £107, as compared with £522 in the previous year. It was hoped, therefore, if the beds in the sanatorium could be occupied continuously and public interest sustained, that it would be possible in future years to balance income and expenditure without increasing the charge to patients, and also to clear off the accumulated deficit of past years. In the course of the year Dr. J. B. Stelfox had endowed two cots in the sanatorium in memory of his wife.

## Ireland.

### LOCAL GOVERNMENT COMMISSION: NORTHERN IRELAND.

At a meeting of the Local Government Commission (Northern Ireland) in Belfast on February 25th, when Professor R. J. Johnstone, M.P., M.D., was in the chair, evidence was given on behalf of the profession of Northern Ireland with regard to the public health system of administration. Dr. J. S. Darling, president of the Ulster Medical Society, Professor W. J. Wilson, professor of hygiene in the Queen's University of Belfast, Dr. W. Lyle, dispensary medical officer (County Tyrone), and Dr. W. Burns, dispensary medical officer (Belfast Union), had been appointed by the Ulster Medical Committee to give evidence. The chief points dealt with were:

1. The great abuse in the issuing of red and black "lines," which were sometimes given out by the wives, children, and even servants in the house of the wardens.
2. Anomalies of salaries and of extent and distribution of areas of districts.
3. General lack of co-ordination and unity, and want of a controlling head.
4. A recommendation that there should be a Ministry of Health for Northern Ireland, with a statutory advisory committee. This Ministry could be under one of the existing Ministries, with a specialized officer and a chief executive medical officer.
5. That housing should be under this Ministry.
6. That there should be county health committees of the county councils, each with a whole-time medical officer as its chief executive head, and with representatives from various bodies, such as insured societies, child welfare and school attendance committees, etc. The boards of guardians and rural district councils should no longer be concerned with hospitals, as they were not elected for that purpose.
7. That each whole-time county medical officer of health should be responsible for the health of the county, and the dispensary medical officers, as local health officers, should report all matters to him, and leave prosecutions, etc., in his hands.

Dr. Lyle thought that there was a majority of opinion in favour of reverting to the old dispensary committees. The unanimous considered opinion of the Ulster Medical Committee was that Insurance Acts benefits should be extended to Northern Ireland, provided that the interests of the dispensary doctors were adequately provided for, but that this was more in the interests of the community than of the doctors; the working classes thought they were being deprived of something which was being granted to their brethren in England. Dr. Burns considered the dispensary system out of date, and that the benefits under the Act would have an elevating effect upon the working man. It was recommended that all rate-aided hospitals should be managed by local committees under the county health committees: they should be graded as central hospitals for large areas, and hospitals of the type of cottage hospitals for the smaller centres of population; in addition there should be special hospitals and hospitals for innumerable cases. A large laboratory for pathological work should be set up in Belfast, with a full equipment to undertake all pathological, bacteriological, and biochemical work for the health authorities of Northern Ireland. At present, Professor Wilson stated, the University provided a laboratory free of charge, and paid for a staff of assistants to enable him to discharge this duty; some county councils paid a retaining fee, for which he had to do the necessary work, but it did little more than pay incidental expenses for electric light, and so on.

### THE VETERINARY MEDICAL ASSOCIATION.

The council of the Veterinary Medical Association (Irish Free State) had under consideration at a recent meeting the report of the discussion in the Senate on the amendment to the public health section of the local government bill specifically providing for the veterinary inspection of dairy cows and of meat. From the discussion it might, it was thought, be inferred that veterinary surgeons were only employed under the Public Health Acts for the purpose of inspecting milk and meat as they were presented for human consumption, no mention having been made of their indispensable services in inspecting the sources of these food supplies—the dairy cows and the carcasses of beasts in the slaughterhouse. The veterinary profession, it was said, wished to make its position clear, and to inform

the public of the danger of diseases being communicated from animals to man through the consumption of milk and meat from diseased animals; 80 per cent. of the cases of abdominal and glandular tuberculosis in children were contracted by drinking milk from tuberculous cows. Septic sore throat in the human subject had been attributed to drinking milk from cows with diseased udders. Many fatal cases of meat poisoning had ensued from the consumption of meat from carcasses that had been affected with disease or had been improperly handled. It was, therefore, of vital importance to the health of the community that qualified veterinary surgeons should be made responsible for the inspection of dairy cows and of milk, of carcasses of animals slaughtered for human consumption, and of meat stores. To ensure this it was obviously a wise step on the part of the Minister for Public Health to have had an amendment inserted in the public health section of the bill specifically providing for veterinary inspection under the Public Health Acts, otherwise it would not be compulsory by law to have this inspection conducted by qualified men. Apart from the public health point of view, inspection was essential in connexion with the export trade in meat in order to ensure the standard of the meat exported. In the United States, Canada, Australia, New Zealand, and the Argentine all the meat exported had to be inspected by veterinary surgeons. In all the large cities of Great Britain veterinary surgeons were now appointed for the inspection of dairy cows, milk, and meat.

## France.

[FROM OUR OWN CORRESPONDENT.]

M. JUSTIN GODART, Secretary of State for Hygiene, has declared war on the abuse of the public by advertisements of drugs and the like in the general press. He has written a letter to the editors of the lay papers suggesting, perhaps rather sceptically, that the word "cure" should never be printed, and that anyone who offers his services in a medical capacity should do so under his own name, and accept full responsibility. We are rather afraid that M. Godart's action will not go beyond the stage of good intentions. The publishers who derive a substantial income from so-called medical advertisements are not very likely to commit harakiri unless some stringent law takes hold of their trembling hands. The medical profession would probably be content if, to begin with, the great publicity given to venereal quackery were checked. We think, indeed, that the best way of dealing with these problems is to open wide the doors of our hospitals to the public and to retort on the quacks by making more widely known the help the hospitals are always ready to render. It is a curious, but after all quite explicable, fact that since patients (paupers excepted) have had to pay a small fee, even in the out-patient department, consultations there are far more highly valued.

### *La Robe Rouge.*

It is with great regret that we see the popular master Professor Letulle, retire from the chair of pathology in Paris. He is succeeded by his pupil Dr. Roussy, well known for his work on cancer; he was, with the late Professor Bergonié, one of the founders of the anticancer centres in France.

### *An Ominous Verdict.*

Dr. Roussy's name came rather prominently before the public when he was called to the witness-box some weeks ago in the Umiska case. A patient, a Pole, was shot in his wards by a young actress. It appeared that the man was dying from advanced cancer, and that he himself had begged the woman he loved to put an end to his agony. The mere statement of facts by Dr. Roussy raised such a wave of sentimental pity that the prosecution was swamped, and the jury very nearly congratulated the woman. The consequences of the verdict were practically immediate, for we have just heard of a sister, in similar circumstances shooting a younger sister who was suffering from tuberculosis. It is the old problem of euthanasia confronting us again, but now the public is giving the answer. We are

afraid of what is coming next. Heirs may prove to be too kind-hearted, and certainly we shall have to be more than cautious when asked to give a prognosis. The new world still needs the old commandments.

#### *Bacteriolytic Action of River Waters.*

Professor Arloing has presented to the Academy of Medicine a striking report on the antimicrobial action of the waters of some rivers as regards the intestinal flora. Who would have believed that the river Rhone kills the typhoid bacillus, that our Seine is inimical to the Shiga bacillus of dysentery, and highly polluted waters, such as the Havre harbour, are fatal to the colon bacillus? The antimicrobial action is more marked after the passage through a town, and bacteriolysis seems to be more of a biological than of a chemical character. If these observations are confirmed they may have a far-reaching influence on practical hygiene. But that the waters of our rivers are not the "purée de microbes" they are reputed to be is well proved by a common experience; I refer to the swimming parties of our boyhood which we enjoyed in the Seine near the Pont de la Concorde, when immunity baffled the severe laws of prophylactic hygiene.

#### *The Government and the Profession.*

Underground rumours and many symptoms point towards an impending conflict between the traditional sense of medical independence and the stringent jacobinism of administration. At the Conseil de la Faculté the chair of ophthalmology has not been given to the official candidate of the Government. *Inde ira.* Again, though the Chambre des Députés has voted that a new chair of puericulture should be created, the same Conseil rejected the proposition, pointing out that such teaching was already given by several of our professors. As a matter of fact, the true reason is that our Faculté refuses to be governed by politicians. Now the whole profession is roused by a new bill proposing that we shall keep account books stating the names of our patients with the amount of fees they may have paid us. Our Chamber has failed to understand that such a thing as professional secrecy is at the very base of our dignity and pride. Here we come to a *non possumus*, and tax collectors will have to deal with us in some other way than with the honourable corporation of grocers. After all, we are not so far from the times when Fouquier-Tinville sent some nobleman to the guillotine on the charge of "suspicion of being suspicious."

G. MONOD.

### **Medical Notes in Parliament.**

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

THE introduction of the Nursing Homes Registration Bill, a keen debate on the position of medical referees under the Workmen's Compensation Act, and a second reading debate on the Public Health (Scotland) Amendment Bill have made the past few days in the House of Commons particularly important from the medical standpoint. The estimate for the Ministry of Health in 1925-26 amounts to £19,525,977, against £19,503,771 in 1924-25. The latter figure includes Supplementary Estimates. For the Scottish Board of Health £2,556,885 is asked, against £2,497,842 in 1924-25. The grant for universities and colleges is raised from £1,272,970 in 1924-25 to £1,580,500 in 1925-26.

The Factory and Workshop Acts (Amendment) Bill, which was promised in the King's Speech, has not been introduced yet, and the Government is understood to be reconsidering the proposal in it to transfer certain medical inspection duties from the Ministry of Health to the Home Office. When a similar bill was introduced last year, Dr. Fremantle, on behalf of the Medical Committee of the House, gave notice that he would move its rejection as a protest against this proposed transfer. The Medical Committee will meet again on March 9th to consider whether the Births and Deaths Registration Bill should again be introduced and to debate other medico-political issues.

#### **Bill to Amend the Workmen's Compensation Act: Medical Referees—Nystagmus.**

The Workmen's Compensation Bill, introduced by Mr. Cape on behalf of the Labour party, came up for second reading on February 27th, but, after debate, was rejected by 227 to 147. The debate turned largely on medical issues such as the responsibility and impartiality of medical referees, the scheduling of industrial diseases, and the treatment of miner's nystagmus.

A preliminary question was put on February 26th by Mr. T. Williams, who asked the Home Secretary if he was aware that in certain cases the medical referee under the Workmen's Compensation Act had been known to be almost a permanent representative of employers in compensation disputes, and whether he would take steps to ensure that in future all medical referees should be independent both of employers and employees. The Under Secretary for Home Affairs, Mr. Godfrey Locker-Lampson, said he knew of no such cases among medical referees at present appointed under the Act. It was a condition of appointment that a medical referee should hold no personal employment either on the employers' or on the workers' side. Medical referees were enjoined that they should as far as possible avoid cases likely to come before them in their official capacity. It had not been found practicable to impose any further restriction.

#### *Debate.*

In moving the second reading, Mr. Cape said that in it the Labour party asked for some of the outstanding disadvantages of the Act of 1923 to be amended. The insurance societies, indemnity societies, and employers' organizations were, he said, now so equipped with a medical service that within a day or two of an accident the employer's medical officer had an opportunity of examining the man, and the chances of malingerers were very remote. The Labour party thought the present system put too much on one medical man. Under the present procedure the injured man was first examined by the employer's doctor. He had then to get a report from his own medical man, and very often this was difficult, because as a rule medical men did not take kindly to supplying these reports. All this evidence was submitted to the medical referee, who nearly always lived in the district where the accident happened. The result was that it was difficult to bring in a man who was impartial and not in some way connected with the parties. The referee was only human; he would probably do his best in the examination of the man, but, generally speaking, in the areas where these accidents occurred the medical men were not experts in any particular subject. The examination should be made by three medical men, who should be independent both of the man and the employers so far as the industry was concerned. It was asked also that the referees should not be concerned directly or indirectly in practice in employers' liability or workmen's compensation cases, either on behalf of an employer or a workman, or by an insurer interested in such cases. The Labour party did not ask that this medical board should consist of men whom they approved, but they asked for independence, and that only those of the highest professional standard should be employed on decisions which involved so much to the workers.

Turning to the schedule of the bill, Mr. Cape said that in Cumberland the percentage of cases of miner's nystagmus was high; he met many men who had come out of the mines with nystagmus and were receiving no compensation. The doctors stated that the nystagmus had ceased because oscillation had disappeared from the eye. He drew attention to the appearance, new so far as he knew, of silicosis among miners. Parliament had dealt with that under the Silicosis Act, but the men were at present excluded from the Workmen's Compensation Act. Five deaths had occurred in Somerset and the Radstock district; and other coal-miners were in bad health owing to what the medical authorities declared to be the results of working in stone of a siliceous nature. He knew a coal-miner in Cumberland who had been unable to follow his occupation for fifteen months, and the medical man said this was the direct result of stone dust. The Labour party asked that all these conditions that could be traced as direct results of men following their industrial employments should be included for workmen's compensation.

Mr. Greaves-Lord, in moving the rejection of the bill, said he did not believe in compulsory reference of compensation cases to one referee, and he did not think the position would be improved by increasing the referees to three. It was going too far to say that no medical referee should engage in or be concerned, directly or indirectly, in employers' liability or compensation cases or by insurers interested in such cases, and should not be concerned in private practice in the district. The proposal would deprive referees of any chance of practising in the district of the court, which might be very large. That meant really that the referees would have to be permanent officials of the court. The best system was that which attracted the best class of medical man, and to do that he must have the right to practise, and trust must be put on his honour when appointing him medical referee. The Home Secretary already had power to add diseases to the schedule and modify the conditions of that Order at any time; the Medical Research Council had been considering the matter. There was a great division of opinion among medical men to-day, first as to what miner's nystagmus was, and secondly as to what was the best treatment for it. Dr. Court, who had been connected with the Miners' Federation in Derbyshire for many years, who was known as a man very sympathetic to the workers and as one who had an almost unrivalled experience of miner's nystagmus, held that no compensation should be paid to a man in respect of

nystagmus for more than six months; if compensation were paid longer it was likely to continue the trouble and bring on very serious after-effects.

Sir Henry Slessor said it would not be right to suggest that any accusation or suggestion had been made against the medical profession by the bill's proposal on the medical referees, but there was a feeling among Labour members, with direct experience of the working of the Workmen's Compensation Act, that they would be in a safer position and have a better tribunal if there were three doctors on it instead of one.

Sir Richard Luce, speaking as one who for three years acted as a medical referee, supported the bill. He was not sure that its proposals about referees would be workable in the present form, but he wished to see the question of the referees reopened. Up till now the medical referee had been able to practise in the locality, but had not been supposed to act in a case with which he had come into personal contact. That had not absolutely held good, and in many instances strict enforcement had been extremely difficult. Most medical referees were members of the staffs of hospitals. There they came into contact with many cases of workmen's compensation, the people being their patients, and for this work they received no remuneration, but gave their services as honorary members of the staff. When the medical referee had had to give reports of cases on behalf of the man or of the employer, he had as a rule stood down from being referee. When he had only seen the case as an ordinary physician or surgeon, then he had as a rule been allowed to act. This had brought about considerable difficulties, and he himself had resigned from being medical referee some years ago because he found he was getting mixed between his patients and his duty as a medical referee. While agreeing that some other method of appointing medical referees should be arranged, he foresaw great difficulties, unartificially by the framers of the bill. The value of the appointment as medical referee, even in a large industrial area, was very small. His recollection was that in no year did his remuneration as referee exceed £50. If there were to be whole-time referees under the stringent rules of the bill the working expenses of the Act would be greatly increased. It would, he thought, be difficult to get three whole-time referees for a given case. To do so it would be necessary greatly to enlarge the areas. If there was to be an impartial whole-time man he did not think that three referees would be necessary. It would be better if the schedule were rearranged by the Home Secretary. An alteration should be made in respect of nystagmus. There were many cases which suffered from nystagmus in the early stages—that was to say, from oscillation of the eyeballs. That oscillation passed off, leaving nervous symptoms which caused just as much disability. It was extremely unfair that a man should be deprived of benefit just because he had lost one outward symptom. Many other diseases ought to be added to complete the schedule of the bill, including miner's beat-knee. At present beat-knee and beat-elbow were treated on different terms, though both were caused by constant pressure on hard substances.

Dr. Drummond Shiels said that the Home Secretary had added sixteen diseases to the schedule in twenty years, but they had been recognized for a long time before they were added. Phthisis caused by dust or other irritants which had long been recognized as predisposing causes of the disease should have been on the schedule long ago. The suggestion that if a miner got compensation for nystagmus for more than six months it would considerably aggravate the disease seemed to him in the nature of the new psychology. He feared that the clause of the bill on medical referees was not workable. The Labour party might well consider having three referees—one the man's doctor, one nominated by the employer, and one an outside doctor. There should be a panel of three to obviate groundless dissatisfaction. Very often medical referees were blamed and suspected of bias, owing largely to ignorance on technical points on the part of those affected. He pointed out that in cases of nystagmus it would be impossible to get three eye specialists as a panel, to conform with the conditions of the bill.

Mr. T. Williams said that men who were so far recovered from nystagmus as to have lost the oscillation of the eyeballs were not only deprived of compensation, but were also deprived of their employment. Colliery companies hesitated to re-employ a man who had suffered from nystagmus. In practice the provisions for medical referees did not work out well. It too frequently happened that a man with undoubted medical or surgical skill was constantly found in court taking the side of the employers in compensation disputes. It could almost be said that he was constantly acting as the professional representative of a body of insurers or employers, yet on the morrow they found this representative of employers or insurers acting as referee in a compensation dispute. Without impugning the honesty or devotion of medical men, he submitted that it gave rise to grave dissatisfaction when workmen were called upon to accept as final the decision of a medical referee who was constantly employed and paid by those interested in having these applications rejected.

Mr. G. Locker-Lampson, Under Secretary for Home Affairs, said the Holman Gregory Committee on Workmen's Compensation had unanimously rejected the proposed board of three referees because it would be very costly, because the machinery would move more slowly, and because there was no real case for a change, as the ban against medical referees acting in any compensation cases or appointment of whole-time practitioners in the district would mean that and that would lead to a very heavy extra charge. These practitioners would not get sufficient work unless the areas were grouped into larger districts, and they would lose touch with general practice and gradually become less efficient. He agreed

with the Labour party, however, that a close watch ought to be kept over the present situation, and any representations made would be carefully considered by the Home Office. The question of medical practitioners could, however, be dealt with by an Order of the Secretary of State, or by regulations, and was not a case for legislation. For these reasons the Government could not accept the medical part of the bill, nor could it accept the proposed additions to the schedule dealing with diseases produced by dust and diseases of the eye. The objection to the inclusion of miner's nystagmus was that it would stereotype the description of the disease and would fix the final terms of compensation; it was inadvisable. A Committee of the Medical Referees Council had sat on this, and had reported that the existing description of miner's nystagmus was already very much too wide; it recommended a stricter standard. The Industrial Diseases Committee had advised against the inclusion of phthisis under the Compensation Act of 1906. But if it was shown that in an employment in any industry the individual employed suffered from the inhalation of silica dust the Home Office could include the employment under the Silicosis Act of 1918. No legislation was required. The Mines Department was looking into the question of silicosis, and if a case was made out that in boring through rock to get at the coal there was inhalation of silica dust, then a silicosis scheme would be made by the Home Office and the people affected would get compensation. [As reported above, the bill was rejected by 227 to 147.]

#### IRELAND.

The Secretary for Scotland, Sir John Gilmour, on February 25th moved the second reading of the Public Health (Scotland) Amendment Bill, which he said was identical with the bill introduced in the House of Lords by the late Government and read a second time last year. Its purpose was to empower public health authorities in Scotland to provide insulin for sufferers from diabetes who required assistance in obtaining the treatment. Since early in 1924 some local authorities had provided insulin, and the bill was to regularize their position.

Mr. James Stewart, who had been Scottish Under Secretary for Health in the last Government, pointed out that though the bill only provided for the supply of insulin in diabetes, last year's bill proposed that where the Scottish Board of Health considered any other disease required special treatment and an Order were passed by both Houses of Parliament, then the Board would be entitled, without a further Act, to provide for the treatment of these other diseases. As the price of insulin had fallen since last year and doses could now be provided for a few shillings weekly, the necessity of dealing with the one disease of diabetes was not quite so great. He asked the House to consider the possibility of the discovery of an effective treatment for cancer. If the procedure by Order were not adopted deaths might occur while another bill was being passed.

Sir John Gilmour appealed to members to read the bill a second time. He would do everything he could to ensure that insulin was supplied as freely as necessary to those who really required it, but he could not undertake that when the bill was in Grand Committee the extended provisions of last year's bill would be inserted.

Discussion was interrupted by other business, and the second reading of the bill was postponed.

#### NURSING HOMES REGISTRATION BILL.

The Nursing Homes Registration Bill, presented by Mr. Gerald Hurst, was read a first time in the House of Commons on February 25th. Mr. Hurst had previously explained the provisions of the bill to the Medical Committee of the House of Commons, which, subject to minor amendments suggested by the British Medical Association, had approved it. In introducing the bill Mr. Hurst said that it was uncontroversial and was backed by members from all parts of the House. At present the phrase "nursing home" had no meaning. Any person could call his or her institution, however ill run, a nursing home, however unskilled or untrained the nurses might be and however extortionate the charges. The prevalence of these bogus institutions dragged down the prestige of deserving ones, and their expense was a drain on public resources. The bill provided for the registration and inspection of nursing homes, so that no institution could be carried on as a nursing home by unqualified or unsuitable persons, or where the nursing or domestic staff was ill accommodated, the ventilation bad, or the lighting and warming inadequate. From January 1st, 1930, those having charge of the management must be State registered nurses. Nothing in the bill was intended to preclude anyone unconnected with the nursing profession being registered, but the matron or person in charge must be fully registered. A person refused registration could appeal to the Minister of Health, who could appoint a referee to deal with the complaint. The question of proprietorship was unaffected. Though the bill had been drafted by the College of Nursing, it was not intended to favour any section of nurses, but to help all. The promoters were anxious to meet all interested in the question so that the bill would be regarded as non-controversial. He appealed to the House and the Ministry of Health to help its progress.

The backers of the bill include Dr. Fremantle, chairman of the Medical Committee of the House, and Sir Henry Slessor, ex-Solicitor-General.

In consequence of alterations suggested by the Ministry of Health and by the Medical Committee of the House, the publication of the bill has been postponed for a few days.

**Maternity Homes.**—The Minister of Health has stated, in reply to a question, that he was not aware of any general complaint that the fees charged in maternity homes were too high, although there

was evidence that in certain cases the fees asked might have deterred some women from entering the homes. He had recently circularized the authorities of grant-aided maternity homes, pointing out that, while women should in general pay what they could reasonably afford, no necessitous woman should be excluded from these homes merely on the ground that she could not contribute a certain sum to the cost of her treatment. On June 30th, 1924, the Minister of Health had issued a circular calling the attention of local authorities to the importance of establishing effective ante-natal clinics and of making adequate provision for the care of women about to become mothers, and to other measures for reducing maternal mortality.

**Ministry of Health Staff.**—In reply, on February 26th, to Lieut.-Colonel Horlick, Mr. Neville Chamberlain said that the total cost of the medical staff of the Local Government Board, for salaries and for travelling and subsistence expenses, was £30,420 in 1914-15, and in 1918-19, including bonus, £35,743. The medical staff of the Ministry of Health cost £56,985 in 1919-20 and £121,454 in 1923-24, while the estimated cost in 1924-25 was £122,910. The figures for 1923-24 and for 1924-25 included the salaries and expenses of the regional medical officers. Approximately four-fifths of the cost of this last service was recovered out of national health insurance funds. In reply to a further question, Mr. Neville Chamberlain said that three new medical officers had been appointed to fill vacancies. Answering Dr. Graham Little on the same day, Mr. Chamberlain said that in the Ministry of Health one assistant principal had been promoted to the rank of principal since May 1st, 1924.

**Pensions Medical Officers.**—Colonel Sir Arthur Holbrook, on March 2nd, asked the Minister of Pensions what were the special qualifications, medical or otherwise, of each of four named officers without overseas service, which rendered their retention in the service of the Ministry, in the interests of the pensioner, more desirable than that of the officers whose full-time services were out to be terminated; whether he was aware that one of their cases with a war disability whose services were in the year 1916 and had practically no experience in the medical practice of his profession since that date, having been employed by the Ministry of Pensions, since he joined the Ministry, on purely administrative duties of a subordinate nature during the past five years; and whether he had been told that he was to succeed an officer with overseas service and a war disability whose services were to be dispensed with, part of whose duties consisted in visiting pensioners at their homes and the holding of medical clinics. Major Tryon, Minister of Pensions, answered that in a reply given to Sir Arthur Holbrook on February 12th he had fully explained the considerations governing the selection of medical officers of the Ministry of Pensions for further employment. It was solely for those considerations that the officers mentioned in the question were being retained. In the reply of February 12th the Minister of Pensions said that the chief considerations determining the continued employment of medical officers in the Ministry were efficiency and the possession of the necessary qualifications for the duties to be performed. Subject to these considerations preference was given to an officer with overseas service, especially if he had a disability.

**Poor Law Infirmaries.**—On February 25th Major Tasker asked the Minister of Health whether, in view of the existing shortage of available accommodation for the sick in voluntary hospitals, and of the steadily increasing needs of the community, he would issue instructions that everything tending to discourage or limit the use by the sick of Poor Law hospitals or infirmaries be removed, and that disqualifications and disabilities be continued. Mr. Neville Chamberlain replied that the question of the best method of utilizing hospital accommodation at present provided under the Poor Law could not be dissociated from the larger question of Poor Law reform. Major Tasker further asked whether steps would be taken to amend Section 46 of the Local Government Act, 1891, to remove the disqualifications to which a guardian or district councillor or a parish councillor became subject when he or his wife or child was admitted as a patient into a Poor Law hospital or infirmary. Mr. Chamberlain replied that pending full consideration of the wider problem in all aspects it would not be desirable to introduce the legislation suggested by Major Tasker.

**Panel Doctors and Pensioners.**—On February 26th Mr. T. Williams asked the Minister of Pensions whether, before taking away the treatment allowance from a disabled ex-service man, he would consider the advisability of permitting the presence, when the man was examined, of his panel doctor, who in many cases had a closer acquaintance with the man's disability than the medical man who examined him. Major Tryon said he understood that the medical profession was not at all in favour of that proposal.

**Institutional Treatment of Tuberculosis.**—The Parliamentary Secretary to the Ministry of Health has stated that, as regards England and Wales, the Minister of Health was satisfied with the accommodation provided by local authorities for sufferers from tuberculosis, except that there was need in certain areas for the provision of additional accommodation for cases of non-pulmonary tuberculosis and for cases of advanced pulmonary tuberculosis. The total number of fresh cases of tuberculosis notified during 1923, the last year for which figures were available, was 79,368. On February 1st last 18,427 cases were receiving treatment in institutions in England and Wales, while those recommended for such treatment who had waited more than ten days was 3,436. It might be assumed that most of these cases had now been admitted.

**Medical Services in India.**—Dr. F. E. Fremantle, on March 2nd, asked when the Government would state its proposals for dealing with the recommendations of the Lee Commission with regard to the medical services in India; and whether the House would be given an opportunity of discussing them before any decision was taken. Earl Winterton, Under Secretary for India, replied that the Secretary of State had not yet received the Government of India's recommendations, though they were expected very shortly. He would prefer to await their receipt before giving any undertaking about discussion.

**Defective Children.**—The Duchess of Atholl, Parliamentary Secretary to the Ministry of Education, said, in reply to Colonel Day, that the Ministry of Education had lately sent local education authorities a circular on the need for augmenting the provision made for defective children. In Manchester 1,370 children were ascertained during 1924 to be mentally defective, in Leeds 296, and in Birmingham 1,220. In Manchester 657 mentally defective children attended school during 1924, in Leeds 279, and in Birmingham 1,186. Children certified as suitable for special schools for the mentally deficient, but now awaiting admission owing to inadequate accommodation, numbered 537 in Manchester and 17 in Birmingham; in Leeds there were none.

#### Notes in Brief.

The reported occurrence of silicosis among coal-miners is under investigation by the Health Advisory Committee of the Mines Department, which has not yet come to any definite conclusion. Any further action must await the Committee's report.

The Departmental Committee on Workmen's Compensation for Silicosis is inquiring into a scheme of compensation under the Silicosis Acts for the grinding trades, but it is not possible to say when a report would be presented.

The Minister of Health is not prepared to depart from the rule that information relating to insured persons shall not be used otherwise than for the purpose of administering the insurance scheme, save with the consent of the insured themselves.

The Government sees no ground for hoping that a further attempt to secure an international agreement for the disinfection of dangerous wool would meet with success, but the Home Office will continue its efforts in this direction.

No new materials will be scheduled for disinfection without due notice to the trades concerned.

The Committee on Food Preservatives is extending its inquiries to include the treatment of flour with chemical substances.

The Home Secretary is looking into the whole question of instruction to the police in ambulance work and first aid.

A survey of the worst elementary schools has been made in the areas of the London County Council, the county boroughs, boroughs, and urban districts of England, and 607 schools out of 5,760 have been mentioned to the authorities concerned as unsuitable in whole or part. A similar survey is in progress in the county areas of England, and the results of the Welsh survey will soon be available.

The number of persons in British India returned as lepers at the census of 1911 was 92,433, and at the 1921 census 85,122. The figures were admittedly unreliable.

In reply to Mr. J. Guest, the Minister of Pensions said that he was not aware of cases of hardship where the failure of ex-service men to apply for pensions under the seven years' limit had been caused by inadequate or mistaken diagnosis by the medical men at an earlier date. If particulars of any such case were supplied it would be considered. Mr. Guest asserted, in a supplementary question, that pensioners had been treated for neurasthenia or debility at various times during the seven-year period, but at the end of that period had been diagnosed as suffering from tuberculosis and had been ruled out. Major Tryon replied that such a case could be considered under the arrangement for the correction of errors which had already been explained.

The average gross cost per inmate in 1923-24 was: in sanatoriums, £136; in county and borough lunatic asylums, £75 10s.; and in Poor Law institutions, £65 10s. The last figure covered all persons in receipt of institutional relief, and not merely sick persons.

The Secretary of State for the Colonies has called on the Governor of the Straits Settlements for a comprehensive report on the high death rate in Singapore, and for a statement of what has been done to improve housing and sanitary conditions since the inquiry held in 1905.

Answering Mr. Robert Morrison, Colonel Stanley, for the Minister of Pensions, said the records of the Ministry did not enable him to supply particulars of the number of appeals, on the ground of tuberculosis, heard by the tribunal during the past two years, nor of the number allowed. Mr. Morrison asserted that many men who had been gassed during the war had since developed tuberculosis of the lungs, but Colonel Stanley replied that that was not under the jurisdiction of the Ministry of Pensions.

Questions relating to the health of merchant seamen are dealt with by the Mercantile Marine Department of the Board of Trade in consultation with the Ministry of Health. The Mercantile Marine Department has a staff of qualified medical officers. The question of modifying the classification of diseases in the statistics of deaths of seamen is under consideration.

Permission has been granted to the Derbyshire and Shropshire education authorities to continue the employment of unqualified dental dressers up to the end of the present year. Legislation will be necessary to provide that expectant mothers can leave prison for the birth of their children. Extra, or special, diet is provided in prison for all expectant and nursing mothers. Inquiry is being made as to the number of births in prison.

## Correspondence.

### SIR JAMES MACKENZIE AND THE SYMPATHETIC INNERVATION OF STRIATED MUSCLE.

SIR,—It is probably not an overstatement to say that the recent work on the sympathetic innervation of striated muscle has created a profound revolution in anatomy and physiology.

The new facts contained in the lectures by the late Professor J. I. Hunter, recently delivered by Professor Elliot Smith,<sup>1</sup> afford an entirely new basis from which to approach a great variety of clinical phenomena.

I wish to call attention to one form of muscular activity which has not so far been mentioned, upon which these discoveries throw light, while at the same time they strikingly confirm a view of muscular action which was formulated and expressed by Sir James Mackenzie from purely clinical observation.

The muscular action to which I refer is that shown in what we term the "viscero-motor reflex," in which there is a hardness and rigidity of the muscles of the abdominal wall, or of some portion of them, produced reflexly by certain afferent impulses from the viscera. From repeated observation and consideration of this clinical condition Sir James Mackenzie was led to point out that there are two varieties of muscular action, one the ordinary voluntary contraction, and this other form shown in the "viscero-motor reflex," differing from the first in its nature, since it does not produce shortening of the muscle, it does not as a rule involve the whole extent of a muscle, and it can last for an indefinite time, or, in other words, is not subject to fatigue as is the ordinary contraction. In the fourth edition of his *Symptoms and Their Interpretation* (p. 78) he said:

"There are different forms of reflex muscular contraction. The cutaneous reflex contraction is accompanied by a sensation; viscero-motor contraction is not necessarily accompanied by a sensation. The cutaneous reflex results in a momentary contraction of the muscle. The contraction of the muscle which arises from the visceral stimulation is persistent. In this persistent contraction of the muscle we get an insight into several processes of a very instructive kind. Light is thrown upon some functions of the sympathetic system at present obscure, and some characteristic features of muscular contraction which have been overlooked are revealed."

There seems to be little doubt that this acute analysis and differentiation corresponds to the activities of the two components of striated muscle, the dual nerve supply, and to the different forms of activity set forth in the lectures by Professor Hunter to which I have referred.

On the basis of Mackenzie's observations it was a justifiable conclusion that striated muscle showed a double form of action, and it is a striking tribute to Mackenzie's acumen and insight that the structural basis has now been demonstrated for the dual activity which he showed to exist.

It forms, as well, another illustration of the value to anatomy and physiology of such accurate clinical observations, which reveal facts and raise problems which otherwise would be outside the ordinary scope of the anatomist and physiologist.—I am, etc.,

DAVID WATERSTON.

The James Mackenzie Institute for Clinical Research, St. Andrews, Fife, Feb. 28th.

### FAMILIAL DIABETES INSIPIDUS.

SIR,—In the report of the last meeting of the Clinical Section of the Royal Society of Medicine in the *BRITISH MEDICAL JOURNAL*, February 28th (p. 410), Dr. C. P. T. East's case of diabetes insipidus following syphilis is referred to. It is stated that I mentioned a similar case of my own with a remarkable family history. In reality, I alluded to a family series of cases of diabetes insipidus recently described by M. Güsslen (*Med. Wochenschrift*, Berlin, 1924, iii, p. 22). A healthy woman married to one of the affected males of the family in question suffered from extreme thirst towards the end of her first pregnancy.

<sup>1</sup> *BRITISH MEDICAL JOURNAL*, January 31st, p. 197; February 7th, p. 251; February 14th, p. 299; February 21st, p. 350; February 28th, p. 398.

This disappeared as soon as the child was born, and Güsslen suggested that the mother's abnormal thirst was due to a diuretic hormone formed by the foetus in her uterus. In fact, her eldest child, after birth, was found to have the familial complaint (paternal side of the family)—namely, diabetes insipidus—whereas the second child was not so affected, and during her pregnancy with the second child she had no excessive thirst and polyuria.—I am, etc.,  
F. PARKES WEBER.  
London, W.I, Feb. 28th.

### HEART STRAIN.

SIR,—The suggestion is made in Dr. Pullar's letter (January 31st, p. 258) and in Dr. Brockbank's (February 14th, p. 332) that theoretically the pressure transmitted backwards from the aorta to the left ventricle during diastole would be greater in the case of a small valve leak than in the case of a large one. The theoretical reason given is that the force transmitted through the small area of the small leak would not equally all over the interior of the ventricular wall on areas of the same small size as the valve leak, thereby producing a greater pressure than with a larger leak. With a larger leak the same force would act on larger areas of the wall of the ventricle, giving rise to a less pressure. This supposed effect is likened to that of the Bramah press.

The conclusion seems contrary to common sense, and there is, in fact, a fallacy in the argument. There is confusion of a pressure (force per unit of area) with a force—namely, the pressure in the aorta—with the force acting on the area of the valve leak. This latter force, if the pressure remained constant, would vary directly as the area of the valve leak. The smaller the area of the leak the smaller this force would be, the pressure remaining constant.

There is no analogy whatever with the effect of a Bramah press, as it is obvious that no aortic leak, large or small, could cause the ventricular pressure during diastole to rise above the aortic pressure. The extent of rise in ventricular pressure due to a leak would depend upon the rate of back-flow, the capacity of the ventricle, and the duration of diastole.—I am, etc.,

Bolton, Feb. 22nd.

E. S. MILLER.

### NERVOUS EXHAUSTION AND LOW BLOOD PRESSURE.

SIR,—I see here many patients from England who have come abroad suffering from "nervous exhaustion." I find that nearly all of them have a blood pressure of 125 mm. Hg or less, and that their improvement coincides invariably, I think, with a rise towards normal of the blood pressure.

Whether this coincidence has ever been remarked before I do not know. I imagine that the exhaustion decreases the tone of the vessels, thus lowering the pressure; and that the fallen pressure emphasizes the exhaustion, and perhaps determines the breakdown. It would be pleasing to understand better this somewhat vague malady.—I am, etc.,

Mentone, Feb. 24th.

D. W. SAWYERS.

### TESTS FOR DRUNKENNESS.

SIR,—After many years' experience as police surgeon I must confess that I have never yet met with an absolutely conclusive test for drunkenness. Spinal puncture does not help, and Babinski's reflex only proves chronic alcoholism (and not always that). I have remarked that patience, ordinary common sense, and absolute impartiality favourably impress the judge, whereas a dogmatic attitude and obvious hostility towards opposing counsel are distasteful to him. The police surgeon, I take it, is in the witness-box to assist the court, and the more experience he has had the greater must his authority be, and the judge knows this. In effect, he becomes in time as much of a specialist at his job as the gentleman from Harley Street is at his, and probably more so in this particular connexion. The latter frequently is called upon to rebut the divisional surgeon's evidence, and I suspect for two reasons. For one thing, he by his prestige is expected to rather overawe his colleague who, for the moment, is in opposition, and, in the event of the case being somewhat of a forlorn one, to lend his weight in securing a mitigation of penalty; and for another, there is a possible chance

of his encountering one whose self-confidence is more easily shaken in the witness-box than his own. But, as a rule, the divisional surgeon must score if he speaks the whole truth, sticks to his opinion, and does not allow himself to be browbeaten by any lecturing counsel.

It is quite true that one occasionally hears weird judgements from the bench, and as an instance I am minded of a recent case in which defendant was acquitted of the charge of being intoxicated but was fined for reckless driving. The point lies in the fact that my evidence, dead against the delinquent, had been confirmed in writing by his own doctor who had examined him shortly after I had made my report at the police station.

These things happen, and possibly are designed to suppress unbecoming conceit. Truly the judge has the last word.—I am, etc.,

London, S.W.15, Feb. 27th.

ATHELSTANE NODDS.

# RESPIRATORY ORTHOPAEDICS.

Sir,—The work that is done in the ear and throat clinics of the school medical service is lessened in value by the fact that tonsil and adenoid cases after operation often cease to attend after the inspection which satisfies the surgeon that the throat is healed and the naso-pharyngeal tract patent. The operative removal of obstructions in the upper respiratory tract is really no more than the first stage of the necessary treatment. The school clinic surgeon who does not make a special study of the respiratory mechanism of the growing child is but half equipped for his work. The school clinic must in futuro include in its range not only diseases of the ear, nose, and throat, but all abnormalities of the breathing apparatus as a whole; in other words, it must develop the study of respiratory orthopaedics. There are here important and still undeveloped opportunities for very fruitful research, the cultivation of which will revolutionize school medicine. The mechanism of which will revolutionize school medicine. The mechanism of which will revolutionize school medicine.

The importance, as for example:

1. The definition of "a normal chest" in the child, as regards (a) skeletal structures; (b) radioscopic and percussion images; (c) auscultation; (d) vital capacity; (e) pulmonary reflexes.
2. The investigation of the altered respiratory mechanism of the adenoid child, with special reference to abnormal respiratory reflexes.
3. The relation of adenoid hypertrophy to enlargement of the bronchial glands, and the clinical differentiation of such non-infective glandular hypertrophy from early phthisis.
4. The elaboration of a definite system of post-operative respiratory gymnastics based upon a sound conception of the special conditions involved, but simple enough to be of general application. Though we all agree as to the necessity of such exercises, they are not generally provided for, and where such provision is made there is little unity of practice.

The study of respiratory orthopaedics will have to be developed upon systematic lines if the school ear and throat clinic is to be, as it should be, and happily often is, not only a centre for treatment, but for the advancement of knowledge by research, and a fruitful corner in the great field of preventive medicine.—I am, etc.,

F. PEARCE STURM, Ch.M.Aberd.

# CAUSATION OF CANCER.

Sir,—In an article, "Early pregnancy and epithelioma," in your issue of December 20th, 1924, Dr. Emery emphasizes what he believes to be the protective power of fat against epitheliomatous invasion.

It is true that epithelioma is not infrequently found on sites with little, if any, underlying fat. But it is, I think, very doubtful whether the presence or absence of fat is of any importance etiologically. In 59 cases of epithelioma which we operated upon in 1924, almost without exception all rested upon, or had encroached upon, well marked adipose superficial fascia. These were cases of "kangri-burn cancer," originated by contact with, and irritation caused by, the kangri, a portable earthenware pot containing burning charcoal and held under the clothes against the skin in cold weather by the Kashmiris. Our experience has led us to the very definite conclusion that heat irritation is the primary factor in the production of such epitheliomata, and that they occur at the site of most continued irritation.

Other epitheliomata—as, for instance, those of the lips and tongue, chimney-sweepers', mule-spinners', paraffin and tar workers'—have the element of chronic irritation in common. Recent work on breast cancer in its early stages, with the evidence of irritation and proliferation induced by blocked ducts and acini, points in the same direction. Chorionic epithelioma may probably depend upon the irritative action of some toxic agency associated with pregnancy, the nature of which is not yet demonstrable. While agreeing with the author on the importance of internal and external body hygiene, I think the most important preventive treatment of cancer is undoubtedly the elimination of all possible exciting causes—the protection from sources of irritation.—I am, etc.,

Ernest F. Neve, M.D., F.R.C.S.E.

Srinagar, Kashmir, Jan. 20th.

# LIME JUICE AND LEMON JUICE FOR PREVENTION OF SCURVY.

Sir,—Neither in Sir Percy Bassett-Smith's letter nor in your editorial comment is there any reference to the experimental work demonstrating the value of potatoes as an antiscorbutic. The Admiralty might well reply to both that an excellent antiscorbutic is carried on board ship in the form of potatoes.

However, in my experience, potatoes as ordinarily prepared have little antiscorbutic value; experimental success may possibly have been due to the animals being fed on unpeeled potatoes containing the "eycs." At a meeting of the War Section of the Royal Society of Medicine on the subject of scurvy the President asked a visitor present for some remarks. The latter had met a famous Arctic explorer once been troubled with scurvy amongst his staff. A party they threw away and came across a depot of tinned food; On return the party were found to have developed scurvy. My first case of scurvy, a child, was fed on oranges and died. Since then I have seen no case of scurvy that has not been rapidly cured by being fed on raw or undercooked meat. Experiments, however, do not give meat a high antiscorbutic value, the explanation possibly being that the experiments were carried out on vegetable-feeding animals. The point of my letter is that the scurvy problem has not yet been solved, and more experimental work is necessary in order that theory may explain clinical facts.—I am, etc.,

F. C. B. GIBBINGS, M.D.Lond.

Southsea, Feb. 23rd.

# MINER'S NYSTAGMUS.

Sir,—In your account of the discussion on miner's nystagmus in your issue of February 21st (p. 362) I am reported as saying, "The cases should be treated for the neurasthenia," and it would disappear and with it the nystagmus."

To one who is familiar with the difficulties of even investigating such disorders, and with the complicated nature of the problems of prevention and treatment, a statement like that appears to be pernicious nonsense. My speech, prepared beforehand and read verbatim, contained nothing to which such an interpretation could be given. Indeed, I specifically indicated the alarming complexities that the psycho-pathological view introduced, though I expressed the belief that we should ultimately be compelled to accept it.

May I disclaim, too, the use of the word "neurasthenia," which is now almost void of clinical meaning.—I am, etc.,

MILLAR CLIPIN.

London, Feb. 27th.

# THE HYPOTONIC (FLABBY) CHILD.

Sir,—What the flabby child needs is open air and sunshine treatment as applied to cases of surgical tuberculosis. The results of treatment of such children with white-flame carbon are baths are very good. The baths are given two or three times a week, exposing for five, increasing to fifteen minutes, first the front and then the back of the body at a yard distance, using a lamp taking 30 amperes and 100 volts, or the equivalent wattage.—I am, etc.,

LEONARD HILL.

Loughton, March 1st.

## TUBERCULIN TREATMENT.

SIR,—I am one of those doctors who watched and learnt Dr. Camac Wilkinson's method of treating tuberculosis with bi-weekly injections of tuberculin from 1910 onwards, and have myself followed out his teaching carefully with very many good results.

From London dispensary work begun early in 1911, and in sanatoriums at Rüdwick, Fritton, and Ockley, we got uniformly good results; and now, in 1925, I have been told evidence exists of 50 per cent. of the tuberculin-treated patients being alive ten years after cessation of treatment, while as control cases only 5 per cent. of the patients who were not so treated were alive, all being cases with tubercle bacilli.

Only yesterday a small but important meeting was held in Central London to suggest opening again tuberculin dispensaries. At least eight doctors were present, possibly more. At that meeting it was emphasized that any medical staff should be paid, as it is highly technical work, requiring skill and care, and must be learnt. But it is work which only requires a couple of hours twice a week regularly, and it is of the greatest possible interest.

Those of us who have worked at it for years believe in it; and it is only those who do not wait for results who reject it. In my opinion there are a large number of untouched cases of early tuberculosis who might be entirely saved from disaster by six months' treatment at very little expense and without the patient losing a day's work. Late cases, too, are frequently much benefited, and in any case the expectoration is minimized and so they become converted into comparatively harmless cases.

My object in writing is to say I will give all the help I can to any doctor who is anxious to see or learn at 37, *Jeffreys Road, Clapham Road, S.W.*, every Tuesday and Friday from 9 to 10 a.m.—I am, etc.,

ANNIE McCALL,  
Director, Clapham Maternity.

London, S.W.9, Feb. 28th.

## Obituary.

## GEORGE SIGERSON, M.D., F.R.C.P.I., M.R.I.A.

We regret to announce the death of Dr. George Sigerson, which took place at his residence in Dublin on February 18th. He was born at Strabane, co. Tyrone, some ninety years ago, but the exact date of his birth is not known; a younger fellow student of Dr. Sigerson at Queen's College, Cork, where he greatly distinguished himself, estimated his age in October, 1921, as being between 85 and 90 years, and added that in his early manhood Sigerson, a very keen student of Irish, published a translation of the Munster Gaelic poets. On graduating at the Queen's University, Sigerson visited Dublin and went also to Paris, where he pursued his medical studies, devoting special attention to diseases of the nervous system. He took the degrees of M.D., M.Ch., and at a comparatively early age became professor of botany, and later of biology, in the Catholic University Medical School, Dublin. As a scholar and writer he won golden opinions from all sorts of people, and his personal charm was such that he was beloved by the students, who held him in the greatest respect and reverence. When the Royal University of Ireland was founded Sigerson took his place in it, adding steadily to his reputation both in science and literature. Under his aegis the National Literary Society was established in Dublin, and as its president during a long term of years he conferred dignity and distinction upon its discussions. Some seven or eight years ago the members of the society marked their appreciation of his services by presenting him with a portrait of himself by Sir John Lavery, the eminent Irish artist, and many members secured engravings of the same marked the esteem in which Dr. Sigerson was held in his profession by making him an Honorary Fellow. He presented to the Royal Irish Academy, and published in its *Transactions*. His eminence as a medical man was acknowledged widely, and he was well known as a litterateur and

a man of science. To the end he enjoyed a large and lucrative practice as a neurologist in Dublin. Among Dr. Sigerson's scientific publications were *Microscopic Researches on the Atmosphere*; *Heat as a Factor in (so called) Vital Action*; *Cause of Buoyancy of Bodies of Greater Density than Water*; *Additions to the Flora of the Tenth Botanical District*; *Relationship of the Inferesences*; and a translation, with notes, of Professor Charcot's lectures on diseases of the nervous system. Since its foundation, Dr. Sigerson had been a Senator of the National University of Ireland. He was a corresponding member of several of the leading literary and scientific societies in Paris. He was married, and had one son and three daughters; one of the latter—the late Dora Sigerson Shorter—won some distinction as a writer of verse. In many of his public lectures and addresses Dr. Sigerson referred to his descent from the Norsemen, and seemed to take particular pride in it. His massive figure, flowing locks, and long flaxen beard were picturesque corroborations of his claim. In his writings are many allusions to the settlement of the Norsemen in ancient Ireland, as, for example:

"The Norsemen were no newcomers in the ninth century. Gaelic writers state that the fair race of the Tuatha de Danaus came to him from Norway where they had settled. If we consider them as early Norse—which I think probable—these were in constant touch with the island before and after the coming of the Southern Milesians. The annals of Ireland recall several intermarriages in ancient times. Thus, in the second century, King Tuathal the legitimate married a Norse Princess, King Cormac MacArt in the third century, the first Christian king, was grandson of a Norse woman. There were two Norse ancestresses in the lineage of Ossian, the last great Pagan Bard—whilst Secundinus, the first Irish hymn-writer in Erin, was the son of one of the Leegbards, who are supposed to have then recently left Norway."

Among Dr. Sigerson's attainments it is probable that the majority of his countrymen would give pride of place to his work as an authority on the ancient Gaelic poetry of Ireland. As a young man he was a great friend of the late Dr. Sullivan, President of Queen's College, Cork, and it is more than likely that he met O'Curry, who died in Dublin in 1862. In his explorations in the highways and byways of Gaelic poetry Sigerson brought into play the vast resources of his learning and his intellectual gifts, while his qualities of sympathy and understanding were enlivened by his delicate literary style, which lent a charm to everything he wrote. As a lecturer upon those literary subjects that were so dear to him he inspired his hearers with a feeling, not only of reverence, but of affection. Sigerson surrendered himself entirely to the charm of the music and poetry that captivated the poet Spenser—with this difference, that while the author of the *Faerie Queene* looked upon Elizabethan Ireland as a stranger looks upon a conquered land, and used the Gaelic gems that he picked up for the adornment of English literature, Sigerson looked upon the English colonial element in his country at the present day as destined to be peacefully absorbed in the revival of a Gaelic Ireland. Upon this point he wrote, in his preface to *The Last Independent Parliament of Ireland*:

"Since the first dividing pale there has manifestly been, in Ireland, a great vital fusing force, which irresistibly attracted all later comers into the nation. Age after age, a palisade of rigid laws was set up, like a stockade, hideous with horrid penalties, like spiked skulls; and age after age that great vital Irish fusing force has broken down and swept away every penal pale, and changed foes into friends."

Sigerson delved in neglected literature of a period "where long forgotten peoples lived, loved, and acted," and it was his regret that, unhappily for history, that literature was long buried in neglect—"locked in an archaic language, like some splendid missal clasped in covers of wrought silver, which could not be opened." Of the Irish literature before the Christian era he says that "it is, indeed, one of the highest honours of Irish monasticism that, though ascetic and zealous in the extreme, it had a liberal, large-minded respect for the literature of the ancients, and preserved it." In his introduction to his second edition of *Bards of the Gael and Gaul* he rejoices that Ireland is the sole representative of that great world which lived and thrived outside the classic camp. The early poems, in which there is no trace of Christian

influence, are quoted as evidence that "when St. Patrick came to Ireland he came, as St. Paul to Athens, before a highly cultured audience."

**RICHARD WILLIAMS, J.P., M.R.C.S., L.R.C.P.Ed.,**  
Consulting Surgeon, Eye and Ear Infirmary, Liverpool.

It is with regret we have to announce the death from influenza, on February 20th, of Mr. Richard Williams, in his 80th year. He was born in Anglesey and began the study of medicine in Glasgow; he took the diplomas of L.R.C.P.Ed. and L.R.F.P.S. in 1870, and that of M.R.C.S. in 1871. After a period of general practice he devoted special attention to diseases of the eye, and spent some time in London and in Paris. He was appointed assistant surgeon to the Liverpool Eye and Ear Infirmary, and afterwards became full surgeon, a post he held for thirty-seven years. He was also ophthalmic and oral surgeon to the Royal Albert Edward Infirmary, Wigan. To the Liverpool Medical Institution he made several important communications on various diseases of the eye. Being a skilful operator and with plenty of initiative he introduced new methods of treatment—for example, the actual cautery in conical cornea, a method of muscle advancement by a single circular stitch, usually done in seven to eight minutes under cocaine with excellent results. In plastic operations on the lids and conjunctiva Mr. Williams showed great skill and ingenuity. Much of this work was known only to his colleagues, as he was diffident in publishing his methods and averse to any appearance of self-advertisement. He was a vice-president of the Liverpool Medical Institution and also vice-president of the Ophthalmological Society. Mr. Williams was the first ophthalmic surgeon to conduct the eye department of the Royal Southern Hospital. He was made a justice of the peace of the city of Liverpool. In 1910 he retired from practice in Liverpool, owing to reasons of health, and resided in Bangor, where he continued to practise his specialty till the end of last year. His professional ability was recognized by his being made a President of the North Wales Branch of the British Medical Association, and his services were frequently claimed by the Carnarvonshire and Anglesey Infirmary in Bangor.

Mr. Richard Williams was a man of strong convictions, sincere and courageous. Passionately fond of his native country, he was a great advocate of nationalism, and a strong individualist. He possessed humour, albeit at times a little sensitive when made at his expence. He was fond of languages and well acquainted with French and Spanish. His breezy, emphatic personality will be missed by many friends. The loss of his elder son, while flying in the war, was a great blow to him. Mr. Williams was buried in Glanadda in the presence of friends and former colleagues. He leaves a widow, who tended him devotedly, and one son; to them we desire to tender our sympathy.

**E. MACDOWEL COSGRAVE, M.D.,**

Formerly President of the Royal College of Physicians of Ireland.

Dr. E. MACDOWEL COSGRAVE, who died at his residence in Dublin on February 17th, was in his 78th year, and was a prominent figure in the professional and social life of Dublin. His educational and professional attainments gained him many distinctions, while his charming personality and his generous disposition won him many friends. He was the son of William Alexander Cosgrave, clerk of the peace for County Longford, and Anna Maria, daughter of Surgeon Ephraim MacDowel, of the Richmond Hospital. He received his earlier education at Kingstown School, and later entered Trinity College, Dublin. He studied at the House of Industry and the Rotunda Hospital, and took the degrees of B.Ch. and M.Ch. (*stipendiis condonatis*) in 1870 and that of M.D. in 1878. He became a Fellow of the Royal College of Physicians of Ireland in 1880, and was President in 1914. Dr. Cosgrave was physician to Simpson's Hospital, Drumcondra Hospital, and Cork Street Fever Hospital, and during the great war was physician to the Dublin Castle Red Cross Hospital. He

was also physician-in-ordinary to the Lord Lieutenant of Ireland. He was professor of biology in the Royal College of Surgeons, a member of the British Medical Association, and honorary member of the Dublin Council of the Biological and Experimental Science Association. He was also a knight and honorary associate of the Order of St. John of Jerusalem. Dr. Cosgrave was the author of many books, including *The Student's Botany* (1885), and several contributions to journals, chiefly relating to hygiene. He was lecturer in zoology and botany in the Royal College of Surgeons in Ireland. He was the author of the official handbook of the St. John Ambulance Association—a book of which more than four hundred thousand copies have been sold. Apart from his professional attainments, Dr. Cosgrave was a well known antiquary and archaeologist, and was widely recognized as an authority on the history of Dublin and its institutions. He knew his native city as it was given to few to know it. He was one of the principal founders of the Georgian Society, to which body he acted as honorary secretary. He was also a member of the Royal Society of Antiquaries, and his writings on antiquarian subjects were many and well informed. He was the author of *The Illustrated Dictionary of Dublin* (1895, second edition 1906), of a catalogue of engravings of Dublin from the earliest times to 1900, and of *Dublin and County Dublin in the Twentieth Century*, all of which are standard works. In addition to such activities, Dr. Cosgrave found time to devote to photography and chess, which were among his favourite recreations. He was president of the Amateur Photographic Society and was an expert with the camera, some of his photographs being works of art. He was also president of the Irish Chess Club, and was the first to play the game with living men as pieces. In these pursuits Dr. Cosgrave's genial personality won him friends in all directions.

**THE LATE SIR CLIFFORD ALLBUTT.**

We are indebted to Sir CHARLES SCOTT SHERRINGTON, G.B.E., M.D., President of the Royal Society, for the following appreciation:

The invitation to offer my brief tribute to the memory of Sir Clifford Allbutt brings home the difficulty, despite the knowledge of his advanced age, in realizing that he is no longer among us; his vitality overflowed like an influence on all about him. Few, of whatever career, can have combined attainments and a distinction of personality and of person such as met in him. Of many and wide interests, some of them seemingly little compatible, such as scholarship and public professional service, these were in him united into the one harmonious outstanding figure admired of us all. The force unifying him was surely pre-eminently the love of his profession—a love which as exemplified in him implied devotion to its highest causes, the upholding of its learning, the cultivation of its best tradition, the organizing of its power for beneficence. Literary expression was among his gifts. The wide audience which his medical writings reached knows this well. And his letters on public matters appearing from time to time were to a yet larger audience always welcome, and not only for their matter but for their manner as well. Moreover, personal letters from him, written much as he would have spoken, had a characteristic charm and freshness and point, humour and picturesqueness, streaming in swift profusion through them from outset to end. One pauses at the sadness that there can be no more of them to come.

THE FINANCIAL SECRETARY of the British Medical Association writes to supplement our record in last week's issue of Sir Clifford Allbutt's many services to the Association. In the seventies Dr. Allbutt (as he then was) held an official position upon the old Committee of Council; he was one of the elected twenty members for a seat on the 1875-76 Council, and attended for the first time the Committee of Council held on August 1st, 1876, at Sheffield under the presidency of Dr. Wilbraham Falconer, another of the old pillars of the Association, who was contemporary with the founder, Sir Charles Hastings, and who held the offices of President of Council and Treasurer from 1870 to 1878.

Dr. NAUNTON WINGFIELD DAVIES of Creigiau, Cardiff, died on February 13th. He was born at Newport, Mon., in 1852, the eldest son of Dr. David William Davies of Llantrisant, whose mother was a lineal descendant of Sir Robert Naunton of Lethringham Abbey, near Wickham Market, Secretary of State to James I. He was educated for the medical profession at the Royal College of Surgeons in Ireland and at Edinburgh; he took the diplomas of L.R.C.P.Ed. in 1876 and F.R.C.S.Ed. in 1891, and was gold and silver medallist. In 1881 he commenced practice at Bridgend, where he continued his professional work till 1897, in which year he forsook medicine for literature. He was the author of *A Day with Hounds and What Came of It*, which had a large sale. In 1898 he wrote *The Secret of a Hollow Tree* and *Chester Cresswell*, both of which received high commendation. He also contributed articles on professional subjects to various journals, and some on hunting and fishing to *Land and Water*. He subsequently took up the practice of medicine again, and in 1902 wrote *The King's Guide*, which was considered his most successful romance. He is survived by three sons and a daughter. His widow contracted pneumonia on the day after his death and died on the following day.

Dr. REGINALD ARTHUR MORRELL died suddenly, on February 19th, at the age of 42, while examining some x-ray plates at the Sheffield Royal Hospital. He received his medical education at St. Thomas's Hospital Medical School, and took the English Conjoint Board diplomas in 1908. He was honorary radiologist to the Sheffield Royal Hospital, the City of Sheffield King Edward VII Memorial Hospital, and to the Chesterfield and North Derbyshire Royal Hospital, as well as lecturer in radiology in the University of Sheffield. He was a Fellow of the Royal Society of Medicine, a member of the Oxford Ophthalmological Congress, and of the Sheffield Division of the British Medical Association. During the war Dr. Morrell had served with the rank of captain in the R.A.M.C., and was radiologist to the 3rd Southern General Hospital. After the war he became radiologist to the Headington Orthopaedic Hospital under the Ministry of Pensions, and, later, clinical assistant in the x-ray department at the Radcliffe Infirmary, Oxford. He was the author of a paper on the after-effects of certain industrial injuries and their treatment by x rays, published in our columns in 1923.

Dr. FRANK D. M. BEATON died at his residence in Leeds on February 2nd. He was a native of Glasgow and went to the High School there, and began the study of medicine at Edinburgh University in 1914. Soon after the outbreak of war he joined the Argyll and Sutherland Highlanders, from which regiment he transferred to the Special Branch of the Royal Engineers, and saw active service in France for over three years. After the armistice he resumed his medical studies, and graduated in July, 1922. In the following year he was appointed resident medical officer to the Edinburgh City Hospital, and took the D.P.H. He had been in practice in Leeds for twelve months, where his skill and kindness of heart had endeared him to colleagues and patients alike. A promising career has been tragically ended by a sudden onset of septicaemia following tonsillitis.

Dr. WILBERFORCE J. J. ARNOLD, colonial surgeon and acting Governor of St. Helena, died on that island on January 29th. He was educated at Belfast, where he graduated B.A. with honours in 1887, and M.B., Ch.B., and B.A.O. in 1894; he took the D.P.H. Oxford in 1913. He served as a civil surgeon in South Africa and in St. Helena during the South African war, 1900-02, and in 1903 was appointed colonial surgeon at St. Helena. He was a member of the executive council, and had twice previously acted as Governor. The late Governor, Colonel Peel, died at St. Helena in August last, while Mr. C. H. Harper, C.M.G., who was appointed to be Governor in December, has not yet arrived. In the meantime the officer commanding the garrison has been appointed to act as Governor. So the colony will have had four Governors in half a year.

We regret to announce the death, in his 58th year, of Dr. GEORGE PETERKIN of Forfar, which took place at a nursing home on January 28th. An Englishman by birth, he went as a boy to reside with his parents in the North of Scotland, where his father was an extensive breeder of shorthorn cattle at Dungleigh, Ross-shire. He was educated at the University of Edinburgh and the Royal College of Surgeons, Edinburgh, and graduated M.B., C.M.Ed. in 1892 and M.D. in 1900; he took the D.P.H. of the Conjoint Board in Scotland in 1897. After acting as an assistant at Hawick, he went, about thirty years ago, to Forfar, where he succeeded Dr. Hunter. He subsequently became M.O.H. for the burgh of Forfar, medical officer to the Forfar Parish Council, surgeon to the Forfar Infirmary and to the police, and certifying factory surgeon. He was an ex-president of the Forfarshire Medical Society and of the Dundee Branch of the British Medical Association. Dr. Peterkin is survived by a daughter and two sons.

Dr. GEORGE SYMERS MILL of Ossett, who died on January 30th, aged 59, was a native of Scotland, and received his medical education at the University and Royal College of Surgeons of Edinburgh. He graduated M.B., C.M. in 1889, and took the M.D. in 1897. He went to Ossett over thirty years ago as assistant to Dr. J. G. Wiseman, and on the latter's retirement succeeded to the practice. He was for twenty-six years one of the honorary surgeons on the staff of the Dewsbury and District General Infirmary, and also held the appointments of certifying factory surgeon and medical officer to the post office. Last month he resigned the post of medical inspector of school children at Ossett. He took great interest in ambulance work and for many years conducted classes in connexion with the local branch of the St. John Ambulance Association. On the outbreak of war in 1914 he, as a major of the R.A.M.C.(T.), was sent to France, where he remained till November, 1915, when he was invalided home; he subsequently did duty at the Military Hospital at Dewsbury. Dr. Mill, who was a member of the Dewsbury Division of the British Medical Association, is survived by an only daughter.

Dr. JEAN CROCO, professor of psychiatry at Ghent, and founder of the *Journal de Neurologie* and of the Belgian Société de Neurologie, has recently died at the age of 56.

Dr. MAURICE DEMENITROUX, the distinguished pupil of M. and Mme Curie, has recently died of progressive anaemia. Shortly before his death he was engaged in the preparation of the salts of thorium.

## The Services.

### DEATHS IN THE SERVICES.

Colonel Robert Isaac Dalby Hackett, C.B.E., Army Medical Staff (ret.), died at Cheltenham on February 15th. He was born on March 31st, 1857, and educated at the Carmichael School in Dublin and at Queen's College, Galway, where he graduated B.A. with first class honours and gold medal in 1877, and M.A., M.D. with honours, and M.Ch. of the Royal University, Ireland, in 1880. He entered the army as surgeon on July 30th, 1881; he reached the rank of full colonel in 1911, and retired in the following year. He served in the Sudan campaign of 1885 at Suakin, and also in the action at Hakin and advance on Tamai, receiving the medal with a clasp and the Khedive's bronze star. He served also in operations in Zululand in 1888. In the South African war of 1900-2 he was principal medical officer of a general hospital, and took part in the relief of Ladysmith, and in operations in Natal and in Cape Colony, gaining the Queen's medal with one clasp and the King's medal with two clasps. He was employed during the recent war and received the C.B.E.

Lieut.-Colonel John Martin, R.A.M.C.(ret.), died at Southsea on January 28th, aged 77. He was born at Cork and educated at Queen's College there. He took the L.A.H. Dubl. in 1870, and the L.R.C.S.Ed. in 1872. He entered the army as surgeon in March, 1874, reached the rank of brigade surgeon lieutenant-colonel in 1897, and retired on June 26th, 1902. After his retirement he was employed for some time at Londonderry. He served abroad in Egypt, India, and Burma for seventeen years, and after his return home was for three years in charge of the Cambridge Hospital at Aldershot. He served in the Egyptian war of 1882, when he was present at the battle of Tel-el-Kebir, and received

the Egyptian medal and the Khedive's bronze star; in the campaign in Burma in 1886-87 he was personal assistant to the surgeon-general, and gained the frontier medal with a clasp. He had a literary bent throughout his career. Twice he gained the Alexander Memorial gold medal, in 1879 and 1885; and he was also the author of two volumes entitled *Contributions to the History of Medicine*; he also won the Howard medal of the Royal Statistical Society of London. After his retirement he published a volume of poetry in blank verse, *A Legend of the Scorn*, an *Idyll of Ancient Britain*. He was also interested in Freemasonry, and took a prominent part in the foundation of a lodge in Burma, of which he was the first worshipful master. He was twice married, and leaves a widow, a daughter, and two sons, both in the medical profession.

## Universities and Colleges.

UNIVERSITY OF CAMBRIDGE.  
At a congregation held on February 28th the following medical degrees were conferred:

M.D.—J. H. Burn.  
M.B.—A. C. Mowle.  
Drs. G. Forssell and R. Knox have been approved for the diploma in medical radiology and electrology.

UNIVERSITY OF LONDON.  
Dr. J. H. Dible has been appointed, as from April 1st, 1925, to the University Chair of Pathology at the London School of Medicine for Women.  
The title of Emeritus Professor of Medicine at University College has been conferred upon Sir John Rose Bradford, K.C.M.G., C.B., J.B.E., F.R.S., who occupied at University College the Chair of Materia Medica, Pharmacology, and Therapeutics from 1895 to 1903 and the Chair of Medicine and Clinical Medicine from 1899 to 1907.

Professor H. R. Kenwood, C.M.G., who held the Chadwick Chair of Hygiene at University College from 1904 to 1924, has been appointed Emeritus Professor of Hygiene in the University.  
The School of Pharmacy of the Pharmaceutical Society of Great Britain has been admitted, for pharmacy only, as a school of the University in the Faculty of Medicine for five years from January 1st, 1925.

The degree of D.Sc. in Biochemistry has been conferred upon Mr. R. Robison, an internal student of the Lister Institute of Preventive Medicine, for a thesis on hexosephosphoric esters and their physiological functions.  
Dr. E. Barclay-Smith, Professor of Anatomy at King's College Hospital, have been appointed Fellows of King's College.  
A course of lectures on medical hydrology, arranged by the University Extension Board in co-operation with the Committee for the Study of Medical Hydrology, will be given at the central buildings of the University from April 27th to May 2nd, 1925. The lectures will be supplemented by demonstrations and clinical lectures at a British spa.

*Matriculation.*  
At the January matriculation examination of the University of London 100 candidates passed in the first division and 758 in the second division, while 60 took the supplementary certificate in Latin.

## UNIVERSITY COLLEGE.

### Annual Report.

During the session 1923-24 the total number of students enrolled was 2,835. Of these 2,285 were taking day courses, 329 evening courses, and 158 vacation courses. The day course students included 513 post-graduate and research workers. Of the total, 2,317 students came from homes in the United Kingdom; 214, including 74 post-graduate and research, came from various parts of the Empire. From European countries there were 177 students: Switzerland 35, France 27, Holland and Russia each 22, Denmark and Germany each 9, Norway and Sweden each 6; 43 students came from the United States of America (17 undergraduates, 24 research and 2 vacation course). From other countries the largest number—36—came from Japan; of these 8 were doing research work. There were 1,696 registered internal students in various stages of degree courses. Of these, 305 passed examinations leading to honours; 59 higher degrees (215 bachelor degrees, 154 with honours); 274 obtained degrees (40 masters, 10 Ph.D. and 9 doctors). The financial statement shows on the maintenance account a total expenditure of £176,594 and income of £168,943, leaving a deficit of £8,051, mainly accounted for by the very heavy expenses incurred in the number of the new buildings and in rates on fluctuation takes place from time to time, according to the financial position prevailing in the country. Steps are being taken to prevent a recurrence of the deficit, and hope is expressed that the University Grants Committee may be able to increase its grant in view of the large donations received by the college through the Rockefeller Trust and other bodies for the erection and equipment of the new buildings.  
The two halls of residence for the college have been full throughout the session, and it is clear that at an early date an extension of accommodation for resident students will become essential.

## Medical News.

THE Fellowship of Medicine announces that there will be a discussion on post-graduate teaching in London at No. 1, Wimpole Street, on March 18th, at 6 p.m. Sir Arbuthnot Lane will preside, and members of the medical profession are invited to be present and give criticisms of the existing Fellowship arrangements and suggestions for their improvement. On March 11th Mr. Oswald Addison will lecture on cleft palate at No. 1, Wimpole Street, at 5.30 p.m. From March 9th to April 4th there will be an afternoon course in ophthalmology at the Central London Ophthalmic Hospital. At the Chelsea Hospital for Women a two weeks' course in gynaecology is to be held from March 16th to 27th, and during the same period a course in chest diseases will be conducted at the Brompton Hospital, including demonstrations of cases, x-ray work, and protein tests. The Royal Northern Hospital, in conjunction with the Royal Chest Hospital, will give an intensive course in medicine, surgery, and the special departments, from March 16th to April 4th. The lectures and demonstrations at 4.30 p.m. each day are free to the medical profession. During April there will be courses in diseases of children at the Queen's Hospital, in proctology at St. Mark's Hospital, and an intensive course in the Hampstead General Hospital. A special course in anaesthetics will be arranged for an entry of four post-graduates, and early application is requested. The syllabus of these courses can be obtained from the Secretary to the Fellowship, No. 1, Wimpole Street, W.1.

THE seventeenth international post-graduate course at Vienna from June 15th to 27th will deal with modern therapeutics, including hydrotherapy, diathermy, serum therapy, and various specialties. The course will be followed by practical and clinical work in various hospitals from June 30th to July 4th. Tickets for the course may be obtained from Professor Dr. Richard Wasicky, Bureau der Wiener Ärzte, Kurse, Schlüsselgasse, 22, Wien VIII. Presentation of these tickets at the Austrian Legation in Belgrave Square, London, will enable a reduction of 50 per cent. on the visa (6s.) to be obtained, and also a tariff of the various Vienna pensions, hotels, and restaurants.

WE published on February 21st (p. 391) a note about hexyl resorcinol, and in the *Epitome* this week (para. 240) an abstract appears of Dr. Yeader Leonard's paper in the *Journal of Urology*, December, 1924. We are now informed by the British Drug Houses, Ltd., that they have prepared some hexyl resorcinol in their laboratories, and, while feeling it premature to offer it for sale without further evidence as to its clinical value, they are willing to supply limited quantities to any medical practitioner who would care to make trial of this preparation in the treatment of infections of the genito-urinary tract.

DR. J. A. HARRIS on his resignation of the post of medical officer of health for Chorley has been presented by the members and officials of the Rural District Council with his portrait painted in oils by Mr. F. E. Jackson. In making the presentation Colonel W. Ince Anderton referred to the tact and courtesy displayed by Dr. Harris during the forty-nine years he had served as medical officer.

At the annual dinner of the Hospital Saturday Fund on February 28th it was announced that the total income from all sources for the past year had reached £107,386, showing an increase of £6,143 over the previous year; the management expenses were 8 per cent.

THE Minister of Health announces (Circular 567, dated February 27th, 1925) that the review of civil service bonus on March 1st, 1925, is based on an average cost of living figure of 80—that is, on the same basis as obtained on March 1st, 1924.

DR. DAVID A. VOLUME has been appointed by the King to be an official member of the Executive Council of the Presidency of the Virgin Islands.

THE late Mr. James M. G. Propit of Glenluce, Wigtownshire, and London, left estate of the gross value of £219,793, with net personalty £213,735. The residue of his property he left to his sister for life, and at her death the residuary estate is to be made a trust fund, of which one-half is to be applied for inquiry into the nature, cause, prevention, treatment, and cure of tuberculosis, and one-half for a similar inquiry regarding cancer as a board of special trustees, which is to include the President of the Royal College of Surgeons of England, shall decide. The trustees may apply the funds of the trust in financing persons or institutions conducting such research, the equipment and endowment of institutions or laboratories for this purpose, and the publication of the results of such researches. After payment of duties it is anticipated that the value of the bequest will be about £160,000 net.

DR. JOHN FRASER, surgeon to the Royal Hospital for Sick Children, Edinburgh, and assistant surgeon to the Royal Infirmary, has been appointed Regius Professor of Clinical Surgery in the University of Edinburgh, in succession to Sir Harold Stiles.

THE committee of the Athenaeum, under Rule II (which empowers the annual election of certain persons of distinguished eminence in science, literature, arts, or for public service), has elected into the club Lieutenant-General Sir W. B. Leishman, K.C.B., K.C.M.G., F.R.S., Director-General Army Medical Service.

A DENTAL travelling scholarship of the value of £250 will be awarded by the treasurer of Guy's Hospital Dental School, upon the recommendation of the Dental Council, next July. Applications must be received by July 1st. Candidates must have been educated at Guy's Hospital Dental School, and will be required to engage in at least six months' practical work at an approved colonial or foreign dental school or college. Further particulars will be found in our advertisement columns.

DR. PAUL DELBET, whose death we announced in the JOURNAL of January 31st, was stated to be surgeon to the Necker Hospital. This was an error; his cousin Pierre holds that position.

THE annual general meeting of the National Baby Week Council was held at 117, Piccadilly, on March 4th, with Sir Arthur Newsholme in the chair. After the chairman's address the certificates of merit won in connexion with the Astor Challenge Shield competition, 1924, were presented. The report of the Executive Committee was adopted on the motion of its chairman, Dr. Eric Pritchard. After the transaction of other business an address on "The formation of character, a problem of child psychology" was given by Dr. J. A. Hadfield, lecturer in psychology, King's College, London.

IN the *Bulletin* for 1924 of the Ophthalmological Society of Egypt a detailed account is given of the annual meeting of the society held in March, 1924, including a paper on glaucoma contributed by Professor E. Fuchs of Vienna. The laboratory at Giza, Cairo, has now been completed and placed under the joint control of the Egyptian Government and the British Commissioner in Egypt. Research work is proposed in connexion with trachoma and other forms of ophthalmia in Egypt, and in our issue of February 21st applications were invited for the posts of director and pathologist. It is hoped that one of the main features of the laboratory will be its use as a centre of ophthalmological teaching in Egypt.

## Letters, Notes, and Answers.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—not necessarily for publication.

Communications intended for the current issue should be posted so as to arrive by the first post on Monday or at latest be received not later than Tuesday morning.

The telephone number of the British Medical Association and the British Medical Journal is Gerrard 2630 (Internal Exchange).

The telegraphic addresses are:

EDITOR of the British Medical Journal, Aitology Westrand, London.

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), Articulate Westrand, London.

MEDICAL SECRETARY, Mediscera Westrand, London.

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Brit-Med, Dublin*; telephone: 4737 Dublin), and of the Scottish Office, 6 Rutland Square, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 4361 Central).

### QUERIES AND ANSWERS.

"H. F.," a medical man suffering from tuberculosis (very slight case), desires to be admitted to a sanatorium, and would be willing to do some professional work as a return.

"CREWEN," who is contemplating turning a room into an operating theatre, asks for suggestions for the best treatment of walls and floor (an ordinary board floor). He asks for details of special floor materials.

### THE TREATMENT OF ASTHMA.

"H. C." writes: I should be glad of suggestions for treating a bad case of asthma in a man aged 49, who resists all the usual forms of treatment, including protein therapy. The attacks, but on an average he is on adrenaline every twenty-four hours and

### INCOME TAX.

"C. G. H. C.," who is on seven months' leave from an appointment outside the United Kingdom, asks how his liability to income tax will be affected by spending a portion of that time outside the kingdom.

Briefly the position is that he is liable to tax in this country in respect of income arising here, but as regards income arising abroad and remitted to him he is not liable provided that he "is in the United Kingdom for some temporary purpose only and not with the intent of establishing his residence therein and has not actually resided in the United Kingdom at one time or several times for a period equal in the whole to six months in any year of assessment" (No. 2 of the Miscellaneous Rules applicable to Schedule D, Income Tax Act, 1918). In applying this rule it should be borne in mind that the "year of assessment" runs to April 5th. Dublin would be outside the United Kingdom for this purpose.

### LETTERS, NOTES, ETC.

#### PYLORIC STENOSIS IN INFANTS.

DR. HUGH T. ASHBY and Mr. A. H. SOUTHAM (Manchester) write: Since the publication of our paper on pyloric stenosis in infants (*BRITISH MEDICAL JOURNAL*, February 28th 1925), we find that the Rammstedt operation was first performed at the Royal Manchester Children's Hospital in May, 1914, with a successful result, and subsequently in succeeding years. Our statement, therefore, that the operation was first taken up in this country in 1918, though true in a general sense, requires some modification in view of the above fact.

DR. N. R. DHARMAVIR (M.O.H. Padliham) writes: I have carefully read (in your issue of February 28th) the article by Dr. Ashby and Mr. Southam on the above subject. During my experience of twenty-five years as a general practitioner and ten years as medical officer to the local maternity and child welfare centre, I have not yet come across a true case of pyloric stenosis. I have, however, over and over again seen cases with signs and symptoms (with the exception of the tumour, on which the writers themselves "lay little stress, as it is often an exceedingly difficult matter to feel the pylorus") as described for the purpose of early diagnosis, and have always ascribed them to injudicious and improper feeding. These cases are easily amenable to careful and intelligent feeding. Peculiar forceful vomiting, constipation, greediness for food, wasting, etc., are such common symptoms among ill-fed infants, and so easily cured, that these must (as the doctors hint) be cases of pyloric spasms and not of atresia. Then what are the crucial signs or symptoms of stenosis calling for an abdominal operation at such a tender age?

#### MOTOR CAR PARKS.

THE Automobile Association, since the war, has been in negotiation with the authorities throughout the country for the allocation of the necessary spaces for parking cars. As a result, 111 large towns and cities now have motor vehicle parking arrangements, and 44 towns have erected signs supplied by the A.A. bearing the words "Motors park here." In Liverpool there are 54 of these signs and in Edinburgh 33. It should be noted that cars must not be parked for unreasonable periods; only for the duration of short calls.

#### A NEW MOSQUITO BREEDING PLACE.

DR. W. E. HAWORTH, late acting director of the laboratory at Dar-es-Salaam, in the *Transactions of the Royal Society of Tropical Medicine and Hygiene*, October, 1924 (p. 162), adduces evidence that mosquitos breed in the crowns of coco-nut palms, where pools of water occur, probably as the result of dew. He urges that no antimosquito campaign can be thorough unless this source of infection is dealt with. His investigations go to show that mosquito breeding continues throughout the year in these pools, even during times of comparative drought, when collections of storm water have disappeared. Within the township areas, such as Dar-es-Salaam and Tanga, the majority of the mosquito larvae detected in these pools were of the biting kind, proved disease carriers predominating at all stations.

#### INDEX CARD CLIPS.

THE "M. H. S." clip has been designed for the use of medical practitioners and business men in hospitals and public institutions for uniting index cards in book formation, so that the cards will fold flat against each other and occupy a minimal space in the file cabinet. The clips are transparent and can be quickly attached to the card, thus uniting those relating to the same case or subject. They may be obtained from Messrs. Bridge and Co., 92, Chancery Lane, W.C.2.

#### VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 35, 38, 39, 42, and 43 of our advertisement columns, and advertisements as to partnerships, assistantships, and locum tenencies at pages 40 and 41.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 95.

# REMARKS ON THE SURGICAL TREATMENT OF GASTRO-DUODENAL ULCERATION.\*

BY  
CHARLES A. PANNETT, M.D., F.R.C.S.,  
PROFESSOR OF SURGERY, UNIVERSITY OF LONDON; SURGEON TO  
ST. MARY'S HOSPITAL.

THE evolution of a gastric or duodenal ulcer is a calamity in a man's life. It attacks during the period of greatest vigour and usefulness. Intervals of complete freedom alternate with weeks of invalidism so that the patient's work is seriously interrupted, and with the passage of time the periods of relief become of less and less duration until persistent incapacity turns him into an encumbrance rather than a useful member of society. Physically he suffers from malnutrition, whilst mentally his fortitude is sapped by the ever-present risk of a perforation into the general peritoneal cavity, a catastrophe which exacts a heavy toll. Working in a hospital it is difficult to form an estimate of the frequency of occurrence of gastric ulceration. But although we always have in the wards cases of this disease, I believe it is relatively rare; or perhaps it would be better to say that of all the cases of dyspepsia which consult the practitioner only a small percentage have an ulcer. This small proportion, however, must be recognized, that by treatment such patients may be saved from chronic invalidism.

THE CHOICE BETWEEN MEDICAL AND SURGICAL METHODS. A most unfortunate controversy has been waged over this question of treatment, so that the impartial observer may be forgiven if he gets the impression that there is a real conflict between the early stages of the malady presents himself, the necessity of choosing between medical or surgical treatment of dietetic measures never arises. Without exception, medical treatment will prove refractory. Amongst these a very large proportion will be definitely cured by some operation. Critics sometimes point to the failures of surgery in this disease, and try to argue that patients would often be as well off without the ministrations of the surgeon. Let us not forget, however, that surgery is only practised properly where medicine has failed, and that amongst such patients the number restored to complete health forms a very creditable percentage.

## DETECTION OF CASES WHERE MEDICAL MEANS ALONE ARE LIKELY TO PROVE INEFFECTIVE.

Why are some ulcers resistant to the best medical treatment? The answer is bound up in part with the imperfectly understood question of the etiology, but also is concerned with the pathology of long-existing ulceration. Herein lies the secret of the possibility of curing gastric ulcers by surgical means. It is helpful to consider the elementary facts of the alimentary canal. They only occur in those parts of the alimentary canal where active gastric juice has access, and even in this area there are selective sites for the ulcerative process. This is more pronounced in the stomach than in the duodenum. The pathologists tell us that histologically these ulcers show characters of their own, and there is no doubt that they are the result of a true digestive process occurring in a part of the stomach wall damaged in some other way. Normal stomach wall is resistant to gastric digestion, and recent researches have shown that this property is possessed by such other normal tissues as have been subjected to experiment. People have attempted to show that in gastric ulcer there is a lowering of the antipeptic power of the stomach mucosa. This is not true, at least at the time when operation is usually performed. Wounds of the stomach heal quite readily. I have seen a

\* Given before the Plymouth Medical Society, December 15th, 1923.

resection of the stomach post mortem nine days after operation, in which the naked eye complete healing had taken place. We do not often get a chance of inspecting our cases so soon after operation, but we have no reason to doubt that the ordinary gastric ulcer heals as quickly. If this were not so, operating upon the stomach would be quite a futile procedure, for we should only substitute a much larger ulcer for the one we had removed. In the evolution of gastric ulcer there probably is a temporary loss of digestive-resisting power in the gastric mucosa, but some other factor is present which prevents the ulcer from healing when the resistance of the tissues to peptic assault returns once more to normal. There would seem to be two reasons why a gastric ulcer refuses to heal. One is infection, the other is the presence of extensive surrounding fibrosis, set up by the extremely irritating gastric juice. Rosenow believes that all gastric ulcers are blood stream streptococcal infections which have their primary origin in diseased teeth, tonsils, or some other focus; whilst the Leeds school think that infection arrives by way of the lymph channels from the right iliac fossa. In the only three cases where I made an attempt, I obtained streptococci from within the tissues forming the margins of gastric ulcers. Infection undoubtedly plays its part in delaying or preventing healing, but it has by no means been proved to be the cause of the primary lesion. The spread of fibrosis around a gastric ulcer extends into neighbouring structures—the liver, pancreas, lesser omentum—cannot contract down. At this stage the ulcer is as incapable of healing as is a callous leg ulcer adherent to the tibia or a cavity in bone itself. The hindrance here is a mechanical one. When the disease is not of recent origin is it possible to pick out those ulcers in which it is worth while to try medical treatment and those in which such treatment is certain to meet with failure? Sometimes this can be done with certainty by x-ray examination. The number of positive diagnoses of gastric ulcer which can be made by radiographic examination increases much with the skill and experience of the investigator. (Figs. 1 and 2.) But allowing

FIG. 1. Ulcer of lesser curvature, showing Haudek's diverticulum, spasm opposite the ulcer, and how the opaque material remains in the ulcer crater as the stomach empties.

FIG. 2.

for this, there are still some cases where an ulcer may be present and remain undetected. Assuming that the ulcer crater can be visualized, we are able to come to a pretty accurate conclusion as to whether surgery is called for or not. Only the smallest craters which have a spiked extremity and penetrate no further than the mucosa will heal over. I think it must be conceded from x-ray observations before and after medical treatment that a few ulcers with demonstrable craters will disappear. The chance of this happening is not a great one. When, however, the crater is of a certain size, and when the ulcer is adherent posteriorly, as can sometimes be demonstrated by the stomach shadow remaining fixed at this point on altering the posture of the patient, we can be certain that so much fibrosis has taken place around the ulcer that spontaneous healing is no longer possible. We shall not commit many errors if we make it a rule to operate upon every gastric ulcer in which a blunt-ended Haudek's diverticulum is demonstrable.

FIG. 3.

FIG. 4.

FIG. 5.—Two ulcers of duodenum; distortion of cap.

FIG. 6.

FIG. 7.

FIG. 8.

FIG. 9.

FIG. 3.—Normal duodenum, showing filled cap and opaque material passing through second part.

FIG. 4.—Ulcer of anterior wall of duodenum; large penetrating ulcer on posterior wall; flattening of left border of cap and ulcer crater.

FIG. 6.—Ulcer of anterior wall and one on posterior wall of duodenum; distortion of cap. This patient also had a persistent fleck.

FIG. 7.—Ulcer of anterior wall and penetrating ulcer of posterior wall of duodenum; distortion of cap.

FIG. 8.—Ulcer of upper border of duodenum, showing fleck remaining in ulcer crater after first part of the duodenum had contracted.

FIG. 9.—Penetrating ulcer of duodenum which was drawn out into a diverticulum by fibrosis.

A most important question is this: Shall we decide against operative treatment whenever the x rays fail to reveal an ulcer in a suspected case? This is most difficult to answer. In some clinics abroad over 90 per cent. correct x-ray diagnoses are claimed, but my experience is that we in this country cannot reach such perfection—at least in hospital practice, where repeated re-examinations and serial methods are precluded by pecuniary reasons or want of time. Often, though the actual ulcer cannot be seen, because perhaps the crater, being plugged with mucus or food, admits no opaque material, collateral indirect evidence of an organic stomach lesion is obtained by x-ray examination—such, for example, as spasm of the pylorus or greater curvature. In such cases we are influenced above all by the clinical history, which may be so characteristic that no doubt can remain that we are dealing with an actual organic lesion.

#### THE PROBLEM IN DUODENAL ULCERATION.

The general pathology of duodenal ulcer is similar in every way to that of gastric ulcer, except that cancer never seems to be grafted into an ulcer in this situation. It occurs, of course, almost solely in the beginning of the duodenum, which physiologically may be regarded almost as part of the stomach. Nevertheless, there are special features about duodenal ulcers which render our attitude towards them a little different. On the whole they are of a smaller average size than the gastric ulcer, and they are much more often multiple. Indeed, observations made during resection of the duodenum indicate that it is the rule for two ulcers to be present. Just as in the case of the stomach, although small they are attended by very extensive fibrosis, which frequently surrounds the common bile duct and cuts into the pancreas.

I have gained the impression, though it does not amount to a certainty, that ulcers of the duodenum can be more readily induced to heal than ulcers of the stomach. Perhaps this is due to the fact that they are of smaller size. I am not sure that it is wise to bank upon this impression, for we know how many of them resist treatment, and if they are allowed to enlarge and burrow into the pancreas removal by operation always becomes a formidable procedure and sometimes proves to be impossible, whilst the walls of the ulcer may have become so rigid that indirect surgical measures, such as gastro-jejunostomy, may be ineffective.

The radiographer's diagnosis of duodenal ulcer is less certain than that of gastric ulcer and the classical symptoms are not always present. Whilst hyperchlorhydria without duodenal ulcer may simulate the disease very strongly. It

therefore comes about that sometimes we open the abdomen only to find no trace of the expected ulcer. In some of these patients I feel sure that a posterior ulcer is present and overlooked. This is extremely easy to do. On several occasions I have only first become aware of the presence of a second duodenal ulcer behind when a resection operation has been begun and the viscera has been in process of separation. I have also seen *post mortem* an ulcer which could not be detected by the pathologist until the intestine had been actually opened. If an ulcer on the anterior wall of the duodenum is so small as to give no visual or tactile evidence of its presence from the outside, the prospect of cure occurring subsequently is likely to be fairly good; little harm, therefore, will probably arise from closing the abdomen without proceeding further. On the other hand, the ulcer may persist. One of my patients had been explored by a surgeon for duodenal ulcer eight years previously to admission. None could be found and his abdomen was closed. The symptoms had persisted. Operation revealed the presence of anterior and posterior ulcers, which were removed by excision of the duodenum. This case is a warning against operating too early after symptoms of duodenal ulceration have appeared. At this early stage an ulcer destined to persist and become callous may be quite undetectable from the outside.

As I have said, the radiographic diagnosis of duodenal ulcer is difficult. Visualization of the first part of the duodenum is not certain for two reasons: it may be hidden by the shadow of the stomach; the exposure may be made whilst the duodenal cap is contracted after expelling its contents, which it does every two or three minutes. Sometimes it will not fill very readily. There are ways of circumventing these difficulties, but it cannot invariably be done. The niche of the ulcer is less prominent and the notch not so distinctive. Going back over my cases with the radiographs, the striking thing is that there always appears to be some deviation from the normal picture whenever good visualization of the duodenal cap has been obtained. There is a spasmodic indrawing, a flattening of the left border, an asymmetrical pyloric canal, a niche, a persistent fleck remaining when the cap has contracted, an irregularity of outline of the cap which often defies precise classification, sometimes only evidence of obstruction to the outflow of chyme from the pylorus, on other occasions distinct hurry in the passage of food into the duodenum. I have made outline drawings of some of these appearances. (Figs. 3 to 9.) If before operation any reliance is to be placed upon irregularity of the duodenal shadow as a sign of duodenal

ulcer, it must be proved that the deformity is a real one, persisting in several films, and not a false shadow owing to imperfect filling. It is worth a surgeon's while to screen his own patients in collaboration with the radiographer. In this way he will obtain a better grasp of the value of radiographic diagnosis of duodenal ulcer.

#### THE VALUE OF TEST MEALS IN DIAGNOSIS.

It is important to consider of what use test meals are in the management of gastric ulcer. From the point of view of diagnosis very little help is to be obtained, but for the medical treatment they are of use. It enables the physician to carry out a rational régime varying in accordance with the quality of the gastric secretion. With this aspect I am not concerned here. Test meals are valuable, but rather as an aid to treatment than diagnosis.

#### CHOICE OF OPERATIVE PROCEDURE WHEN SURGICAL TREATMENT FOR GASTRIC ULCER HAS BEEN DECIDED UPON.

When patients requiring operative treatment have been selected, the path to be followed is even then not quite easy to choose. There are a bewildering number of methods and advocates of them all. Moreover, the inevitable statistics are quoted, and because they are not arrived at by the same methods of compilation they add to the confusion. When one observer, for instance, claims over 90 per cent. good results from gastro-jejunostomy for duodenal ulcer, whilst another, using an apparently identical technique, can scarcely attain to 60 per cent. success, there is obviously some radical difference in their manner of evaluation. Sleeve resection of the stomach is extolled by one surgeon and condemned by another. For the serious student of operative measures for gastric and duodenal ulcer there is only one course to follow: he must select those methods which appear to be based on sound knowledge, and, after trial, endeavour to form his own conclusions as to their relative worth and applicability. Gradually, with experience, and if we remain unbiased, conviction comes that this or that recourse is indicated in any given circumstances. To do this requires unremitting alertness to escape making false deductions. It is more useful to remember the failures or partial failures than the successes. From time to time it is well to read over again the cases which have come under observation. Treatment is best considered under headings.

#### \*A. Ulcer of the Lesser Curvature.

1. *Gastro-jejunostomy* (Fig. 10) alone is being discarded by nearly all operators. It cannot be denied that some patients have been cured by this operation, but it seems proved that the proportion cured is much too small for the operation to be retained as a method of choice. I have records of patients who have got no benefit from it, and when the abdomen was opened after several years the ulcer still persisted.

FIG. 10.—Gastro-jejunostomy.

FIG. 11.—Moynihan's operation for ulcer of lesser curvature.

2. *Resection of the pyloric segment of the stomach, including the sphincter, with implantation of the cut end of stomach into the jejunum.* This operation is often referred to as the Polya operation, but the method of Moynihan is by far the best. (Fig. 11.) It is being performed very extensively just now, and the reports of the results are, on the whole, very satisfactory. It is in most cases a fairly simple operation to do, though in certain circumstances there may be great difficulties to overcome. On several

occasions, when examining the portion of alimentary canal removed, I have received rather a shock in realizing what a physiologically destructive operation had been performed for the size of the pathological lesion. Moreover, to short-circuit all the chyme directly into the jejunum without any of it passing through the duodenum would seem to be a procedure very disturbing to digestion. I have therefore given up this operation except in exceptional circumstances.

3. *Wedge resection of the lesser curvature* (Fig. 12). This operation is usually combined with gastro-jejunostomy, and very good results are claimed by certain surgeons. It is not very widely practised. There are strong objections on experimental grounds, for it has been found in animals to be very upsetting to the normal motility of the stomach.

FIG. 12.—V-resection for lesser curvature ulcer.

FIG. 13.—Sleeve resection for lesser curvature ulcer.

4. *Sleeve resection of the stomach* (Fig. 13). A ring-shaped segment of the stomach is removed which includes the ulcer. End-to-end anastomosis of the stomach is then performed. When the ulcer is some distance from the pylorus this operation has given me very good results. Some surgeons have condemned the procedure. Extended experience may lead me to change my opinion on this matter, but I have not up to the present had a failure of which I know. The operation is sound on physiological grounds, and motility is not interfered with as after wedge-shaped resection. I believe it is the method of choice for such ulcers.

5. *Resection of the ulcer-bearing area of the stomach, including the pyloric sphincter, with axial anastomosis of the stomach to the duodenum.* This procedure goes under the name of the Billroth I method, as it was practised by that surgeon, though it was abandoned by him owing to its high mortality from peritonitis due to leakage. (Figs. 14 and 15.) It is particularly adapted to cases of ulcer on the lesser curvature near the pyloric end. The duodenum is cut across close to the pyloric sphincter and the stomach proximal to the ulcer. An axial junction is made, the open end of the stomach being partially sutured to reduce its size to that of the duodenum. The Billroth I operation was given up because of leakage at the dangerous angle, and only recently has it been tried again. I have performed it more than twenty times and had no trouble following. I believe such immunity depends solely upon care in suturing, and perhaps care in ensuring that the

FIG. 14.

FIG. 15.

FIGS. 14 AND 15.—Resection of ulcer near pylorus by the Billroth I method.

blood supply of the cut edges to be anastomosed is free. It is an operation which appeals strongly on physiological grounds, for, when completed, the appearance of the stomach passing into the duodenum approaches very nearly the normal. Subsequent x-ray examination in my patients has shown good motor function to be present. I believe it to be the method of choice in gastric ulcers on the lesser curvature near the pylorus.

**B. Pyloric Ulcers.**

There is a choice between two methods—the indirect one of gastro-jejunostomy, and the direct method of excision by the Billroth I procedure. It is here especially that good results have followed gastro-jejunostomy in the treatment of gastric ulcer, and there is much to be said for the performance of such a simple procedure, especially as, when the ulcer is surrounded by much fibrosis, pylorotomy may become technically very difficult. When the risk is not too great, however, better results are to be expected from the Billroth I method, as being much less disturbing to normal physiology and eliminating the possibility of gastro-jejunal ulceration. Bland-Sutton in a Hunterian Lecture recommended this course, and it is a policy which I have adopted for the last two years.

**C. The Treatment of Duodenal Ulcers.**

This problem has not been so satisfactorily solved. There is a difference of opinion as to the value of indirect measures, and the technique necessary to employ direct methods is rather difficult to carry out. The authorities of weight in this country, and some in America, claim very satisfactory results from gastro-jejunostomy in a high percentage of patients, and in this they differ strongly from the majority of Continental surgeons. It is always so very difficult to make accurate deductions from medical statistics, where many significant factors are too variable and uncontrollable for scientific exactitude. The divergence of opinion is undoubtedly related to these irremediable facts. I do not think it possible to dogmatize on the operative treatment of duodenal ulcer in the present state of knowledge. It must be admitted, without reserve, that simple gastro-jejunostomy has cured many patients, yet, the pathology of such ulcers being so similar to that of gastric ulcers, which are acknowledged to be exceedingly resistant to indirect measures, the assertion that the proportion of failures is of moderate size cannot be thrust on one side without further consideration. Future experience must settle this question, and for this it is necessary to give direct measures a fair trial. This is being done in the Surgical Unit of St. Mary's Hospital, where we are making it a routine to resect the duodenum in every case where it seems practicable without undue risk. During 1923 and 1924 down to the date of writing this, 28 duodenal ulcers have been operated upon. This is not a large number, but regard has to be had for the teaching of general surgery, and it is undesirable that the number of cases of any particular disease at one time in the wards should be too great. Of these 28 cases, 10 had simple gastro-jejunostomy performed, sometimes with infolding of the ulcer, once with perforation of the ulcer base with a cautery; 18 cases have had duodenectomy carried out. The immediate results of the latter procedure have been uniformly successful in all but one patient, who died on the eleventh day, when the post-mortem examination revealed astonishing healing of the operation site but cardiac muscle degeneration. It is much too small a series as yet from which to make deductions, and time alone will demonstrate whether the results are lasting. The operation is one of the most tedious in surgery, and requires great care to avoid damage to the pancreas and its duct or the common bile duct. After resection of the affected part of the duodenum the stomach is nearly always joined axially to the duodenum so that physiological relations are more nearly restored. A striking fact has emerged from these 18 cases: it is that in a very large proportion there are two ulcers, and the second has several times been discovered only when the stomach has been cut across and access has been obtained to the posterior aspect of the duodenum.

**CONCLUSIONS.**

1. The primary treatment of gastric and duodenal ulceration is always medical.
2. Surgery is indicated when medical treatment has failed, or in recent cases when a large ulcer crater is demonstrable by x rays.
3. It is probably true to say that medical measures can be continued with advantage longer in the case of duodenal than gastric ulceration.

4. For ulcer of the lesser curvature away from the pylorus, sleeve resection is the operation of choice.

5. For ulcers of the lesser curvature close to the pylorus or ulcers at the pylorus, excision of the affected portion of the stomach, including the sphincter, followed by axial union, is best.

6. For cicatrized pylorus following a healed ulcer, pylorotomy is preferable, but gastro-jejunostomy gives very good results.

7. For ulcer of the duodenum it is not decided yet whether resection of the duodenum with its attending increased risks gives results so much better than gastro-jejunostomy that it should replace the short-circuit operation.

## THE TREATMENT OF INFANTILE PARALYSIS;

WITH

A PLEA FOR THE REORGANIZATION OF OUR HOSPITAL SYSTEM.\*

BY

ERNEST W. HEY GROVES, M.S., F.R.C.S.,  
PROFESSOR OF SURGERY, UNIVERSITY OF BRISTOL.

THE subject of poliomyelitis is of much scientific and practical importance, for it is one which should bring pathologist, neurologist, and surgeon into close touch with the general practitioner. Further, it is a good example of one of many administrative problems the consideration of which may serve to shock the spirit of complacent satisfaction with our present hospital system.

**PATHOLOGY.**

Until recently, poliomyelitis had only occurred in the form of scattered sporadic cases, and any information as to the essential nature of the disease was derived from autopsies on late cases. Such information simply pointed to the destruction of motor cells in the anterior horns of the spinal cord, and it was assumed, therefore, that there was an essential destructive process affecting these structures alone. But the occurrence of the disease in an epidemic form both in Scandinavia and in America has given the opportunity for more accurate investigation; not only of human cases, fatal in the early stages of the disease, but also by means of animal experiment. Certain species of monkeys can be inoculated with the disease, and in these animals it often runs a fatal course. It has been abundantly established that the disease is a definite myelitis of patchy distribution. Vascular engorgement followed by round-celled infiltration of the cord is the primary lesion, and it is probable that the destruction of the nerve cells is only a secondary consequence of the inflammation.

That the disease is not confined to the anterior horns is shown clinically by the fact that in the early stages of the disease there is marked hypersensitiveness of the skin, pointing to affection of the nerve roots and their ganglia. The conception of the disease as one of diffuse inflammation has much more than a theoretical interest, because it affords a rational basis for the treatment by absolute rest in its early period.

**CLINICAL STAGES OF THE DISEASE.**

It is easy to distinguish three well marked stages in the disease. The first or active stage corresponds to the period of inflammatory infection of the cord. It is marked by general malaise, a febrile temperature, and paralysis with hyperaesthesia of wide distribution. This lasts for a period varying from a few days to a few weeks. The second or quiescent stage is one of convalescence from the constitutional illness. The temperature is normal and the tenderness and hyperaesthesia have passed away. The paralysis, which was extensive in the stage of onset, gradually disappears in the majority of muscles originally affected, but this recovery of motor function will depend

\* An address given to the Dorset Medical Society, January 16th, 1925.

largely upon the care with which the case is treated, especially in regard to rest and avoidance of meddling attempts to force exercises too early. In a severe case the second stage of quiescence and recovery lasts for one or two years or even longer. The third or final stationary stage is the condition in which the patient is left when all possible recovery of motor power has taken place. Certain muscles or muscle groups are permanently affected with paralysis and wasting of a lower neurone type. If the disease has affected a child in early life, and if a limb is extensively involved, then the growth of the bones in the affected member will be inhibited to a marked extent.

#### TREATMENT IN THE EARLY STAGES.

In the early stages of the disease rest will be instinctively demanded by the patient, whose flaccid limbs and tender skin forbid anything else. Two mistakes may easily be made: first, that in this country, where so far the cases have only been sporadic, the nature of the illness may be overlooked; and secondly, if and when a correct diagnosis has been made, the rest is neither efficient nor secured for a long enough time. When all the limbs and the trunk are affected nothing short of fixation of the whole body on a suitable frame or a plaster bed is satisfactory. The arms must be abducted at the shoulders, the forearms pronated, and the elbows flexed. The legs must be abducted with a very little flexion of the hips and knees, and a full dorsiflexion of the feet. The completeness of this early fixation not only affords the greatest comfort to the patient, but it serves to limit the ultimate extent of the paralysis.

It is in the second or quiescent stage of the disease, when pain and fever have passed and the patient feels capable of moving many muscles, that it is most necessary to insist on the continuation of the fixation. The object now will be to prevent contractures of the joints and to nurse back to useful function the partly paralysed muscles. The fixation should not be so absolute as at first. Each limb will in turn be released from the splint and the joints gently moved. The patient is turned over at least once a week and the back washed.

Dr. Lovett,<sup>1</sup> whose unique experience in the Vernon epidemic gave him unrivalled authority on this subject, collected a large number of observations on the value of various remedial agencies. I am indebted to his writings for the greater part of what I say in this connexion.

It is very doubtful whether massage or electrical treatment has any value, and this applies more particularly to the earlier phases of the disease. The one potent active remedial reagent is muscle re-education. This, reduced to its simplest term, consists in allowing the patient to move his own muscles, aided in such a way that at first each movement shall have to lift the minimum load. Thus the quadriceps may be able to straighten the flexed knee when the patient lies on his side, but it would be incapable of doing this when the leg hangs over the edge of the bed. If the paralysed muscle is asked to do too much or to do it too often, the exercise will do harm and not good, and a recovering muscle may become completely and permanently paralysed. Although a fair idea of strength and function may be gained by carefully aided movements, yet a much more accurate measurement ought to be made by means of a spring balance. It is only in this way, by recording the actual strength of each muscle, that any just appreciation can be gained as to the rate of progress and the effect of remedial measures.

Some may be disposed to think that the picture I have drawn of the treatment of a bad case of poliomyelitis in its early period is fantastic and impossible, implying as it does elaborate splinting and daily exercises of many muscles done with meticulous accuracy, and I am fain to admit that

I have hitherto been speaking of the work of others and not of my own. But I have seen the treatment carried out and can testify to its practical efficiency.

#### TREATMENT OF THE FINAL STAGE OF THE DISEASE.

If all this has been done in the early stage of the disease, then, when the extent and distribution of the paralysis have become fixed and definite, we ought to have no contractures or deformities requiring correction, and the treatment will resolve itself into the provision of appliances, the fixation of flail joints, and the transplantation of tendons. But unfortunately efficient treatment in the early stages of the disease is quite exceptional in this country, partly because the nature of the disease has not been recognized early, partly because practitioners and physicians are not alive to the urgency of preventive surgery, and chiefly because we are so ill provided with suitable institutions where the necessary treatment can be carried out for prolonged periods. In actual practice, therefore, the cases are usually brought to the surgeon in the final stage of the disease with the paralysis complicated by contractions and deformities. The surgery of infantile paralysis consists then in correcting deformities which ought not to have arisen before attempting any reconstruction methods.

I will give an account of two recent cases in illustration of this.

A strong and intelligent boy was brought to me in October, 1922. He was wheeled in, and when lifted from the chair he collapsed on the ground, his legs being doubled up under him. He was able to crawl along the ground and to lift himself up on to a chair by the intelligent use of his arms, which were powerfully developed. Both legs were completely paralysed except for the hamstrings of the right leg. The hips and knees were acutely flexed and fixed by contractions; the feet were flail. He had become paralysed in infancy, and when 18 months old had been taken to one of the city hospitals, where he had been treated by electricity and had had extension applied to his legs. He had been sent home without any provision for after-care, and had remained without treatment for fourteen years under the impression that nothing further could be done. He was admitted to the General Hospital, and within twelve months had undergone arthrodesis of one knee and ankle, tendon transplantation for one knee, and tenotomies for both hips. He is now able to walk with crutches and callipers, and I hope eventually he will be able to discard the former.

The other case was even more striking, because the patient had reached the age of 23 before any serious attempt at treatment was made.

A woman, aged 23, when 2 years old had whooping-cough, followed by a further illness, and she was never able to walk afterwards. Between the ages of 4 and 6 she attended a hospital as an out-patient and had electrical treatment; she was dismissed as incurable. When she came to me in April, 1924, she was paralysed in both legs, which she kept doubled up under her. She had acquired a remarkable mode of progression: she grasped the dorsum of each foot with one hand and then, by lifting each in succession, was able to crawl along with some celerity (Fig. 1). After four operations both knees and hips were straightened out, one knee being fixed by arthrodesis. She is now able to walk with crutches.

In both these cases many years had been wasted—fourteen in one instance and seventeen in the other—and it is almost certain that if treatment had been continued from the time of the occurrence of the paralysis, not only would the degree of paralysis have been much less, but all the operations would have been avoided. Perhaps if these two patients were seen for the first time to-day it would be remarked that after all they are still cripples on crutches, but even this is an immense advance over their condition before treatment, when they were mere helpless crawling creatures unable to move outside their own doors and having to be carried upstairs.

#### THE DISTRIBUTION OF PARALYSIS.

The ultimate distribution of paralysis, as observed by Lovett, has many points of great interest. Paralysis is much more severe and more frequent in the lower limbs than in the upper. The upper limbs recover more frequently than the lower. In the upper limb the severity of the

FIG. 1.—Showing method of walking with the arms.

paralysis is more marked in the proximal than in the distal muscles. The deltoid, biceps, and triceps suffer in this order, whilst paralysis of the forearm muscles is rare. In the lower limb the distal muscles suffer more severely than the proximal. The muscle groups of the leg which are most frequently involved are the glutei, the quadriceps, and the gastrocnemius—that is to say, the muscles associated with the maintenance of the erect position. The tibials and peronei are often affected alone or with the gastrocnemius.

Many of these points in the distribution of paralysis may be associated with the strain put upon the muscles either by gravity or by too early and ill advised attempts at active exercise. Thus the arm is naturally kept at rest or is subjected to no strain, whilst the leg is strained by attempts to walk. The upper arm muscles have to support the weight of the limb and so suffer more than those of the forearm. The lower leg muscles are subject to greater strain in proportion to their size than the upper when attempts are made to walk; and lastly, every effort at standing even with crutches will strain the glutei, quadriceps, and calf muscles, and these are the ones which suffer most. This all emphasizes the fact that the final permanent paralysis is largely determined by failure to rest the damaged structures in the early stages of the disease.

#### TENDON TRANSPLANTATION.

Tendon transplantation is, of course, the most rational and the least mutilating of any of the operations for paralysis. But unfortunately the scope of this method is very limited, as there must be a strong and healthy muscle to take the place of one which is paralysed. It is therefore only of use in cases of limited disease. The results of tendon transplantation in the foot and leg are not to be compared with those which follow the operation in the forearm done for musculo-spiral paralysis. This is due to the greater strength required of the new muscle in the lower limb and to the long and careful preparatory and after treatment. In the foot, there are two movements of the ankle lost by partial paralysis which may be restored by tendon transplantation; these are the movements of flexion and of version. The former is the more difficult problem. Thus, if the gastrocnemius is paralysed, it may be reinforced by taking the tibialis anticus and the peroneus longus and fixing these into the medial and lateral sides of the tendo Achillis, but they can seldom be strong enough to replace the calf muscle. If the dorsiflexors are paralysed the gastrocnemius cannot be sacrificed, nor can it be split, and it is better to use the tendons of the anterior tibial and the long peroneus as a sling by cutting each a hole bored in the tibia, the foot being strongly dorsiflexed. As regards version of the foot, the tibialis anticus and the peroneus longus may be interchanged in cases of paralytic varus or valgus. But whilst all these artificial exchanges of muscle sound so simple and attractive, success can only be achieved by great care and patience. In the first place, it is absolutely necessary to correct all deformity before transplanting the tendon. Thus, in a case of varus with paralysis of the peronei, the inversion must be corrected by wrenching and plaster until the

deformity is overcorrected and the foot lies in a valgoid position. Then, and not till then, can the anterior tibial muscle be brought across and fixed to the peronei or to the cuboid bone. It is useless to employ a transplanted muscle under tension to correct a deformity.

After the transplantation the foot is again put up in an overcorrected position, and after healing has occurred—that is, in about a month—muscle training is begun, but no weight can be put on the foot for four or six months, and a year's after-treatment should be provided for in every case. The operation is only one incident in the treatment, of which preliminary correction of deformity and subsequent muscle re-education are also essential parts.

The other muscle transplantation for paralysis of the lower limb concerns the restoration of the quadriceps. If

all the hamstring muscles are healthy, then the biceps may be taken from the outer side of the leg and the gracilis and semitendinosus from the inner side; these may be sewn to the quadriceps just above the patella, or, better still, passed through a tunnel from side to side in that bone. If the knee flexors are paralysed or weak, then recourse may be had to the tensor fasciae femoris, using the fascia lata as its tendon of insertion into the patella.

#### THE CORRECTION OF DEFORMITIES.

In neglected cases, the common condition is for the hip and knee to be strongly flexed and for the ankle to be flail. But there may be any type of contracture of the ankle-joint—equinus, calcaneus, varus, or valgus, according to the type of paralysis.

In dealing with each of these deformities it is necessary to plan out a method of treatment which can be carried out step by step. Thus, if a flail-foot is the main lesion, it is worth while to do some fixation operation; but if it is part of a general paralysis of the leg which will require the wearing of apparatus, then the foot can usually be fixed by the latter. Generally speaking, it is wise to correct deformities little by

little, and by wrenching or division of tendons and ligaments, rather than by big operations, and especially operations upon the bones and joints. The limbs are ill nourished and repair is both slow and feeble, and extreme correction of deformity done by great force is very liable to be followed by gangrene.

#### The Foot.

The very many operations which have been devised for paralytic talipes is an indication of the difficulty of the problem. Apart from tendon transplantation, the main object of the operation must be to produce stability and a plantigrade position of the foot in walking. Such operations consist in removal of the astragalus, so as to lessen both height and the length of the foot; arthrodesis of the ankle-joint and the subastragaloid joint; or excision of the scaphoid and cuboid, in order to shorten and fix the foot. I have found it to be very effective to perform astragalectomy through an anterior incision, to remove all the cartilage from the astragalus, tibia, fibula, os calcis, and scaphoid, and then to replace the astragalus and to nail the bones together by a long bone nail passed through the sole of the foot (Fig. 2).

FIG. 2.—A method of fixing a flail-ankle. The astragalus has been taken out, all the cartilage taken out and its bed, then replaced and the foot fixed with a long bone nail, driven up from below.

It frequently happens that the quadriceps and gastrocnemius are paralysed and the patient cannot stand. He will often attempt to do so by holding the knee with his hand to prevent it flexing. In such a case, if the foot cannot be prevented from dorsiflexion, then the knee will become automatically locked—that is to say, if the foot is placed on the ground the knee cannot be bent forward without dorsiflexing the foot; hence the suggestion has been made by Putti of placing a bony block in front of the ankle so that dorsiflexion is prevented. This is done by taking a piece from the shaft of the tibia and nailing it into the upper surface of the astragalus so as to stop the ankle-joint from dorsiflexion.

#### *The Knee.*

The contraction of the knee is best corrected by weight extension or by successive plasters rather than by any open operation, and this applies especially to growing children. If, however, the patient has finished growing, an arthrodesis may be done. The knee-joint is opened by cutting the quadriceps above the patella, turning the latter down, and then removing all the cartilage from those surfaces of the femur and tibia which are in contact in a position of straight knee. The cartilage is also removed from the patella and front of the femur after placing the joint in the fully extended position. The patella with its ligament thus acts as a brace, maintaining extension.

#### *The Hip.*

If the hip is much contracted it is difficult to get it down by traction or manipulation, because of the mobility of the pelvis and lumbar spine. It is therefore better to make an angled incision over the front of the iliac crest and upper part of the sartorius (the Smith-Peterson incision) and to strip all the muscles from the anterior superior spine and outer surface of the ilium. It is very seldom necessary to cut either the psoas tendon or the capsule of the joint. This will allow the hip to be put up in full extension, where it is fixed by a plaster sp.

#### *The Inequalities of the Legs.*

If one leg is sound and one extensively paralysed, the latter is usually two or three inches shorter than its fellow, and this will demand special treatment. That which is usually adopted consists in the provision of a high boot for the paralysed and shortened leg. This may suffice for the growing period, but when adolescence is reached something better is available. Various ingenious devices have been suggested for lengthening the short leg. But these are not satisfactory: first, because not more than one or one and a half inches can be gained; and, secondly, because the operation must be done on a weak atrophic bone, the firm union of which will be doubtful. The femur is divided by a Z-shaped osteotomy and then traction is put on the limb.

I think it is very much better to shorten the sound leg, and this may be done by an osteotomy of the femur at the junction of the shaft with the condyles. The shaft is then given a pointed shape, whilst the condylar portion is hollowed out and the former is then driven into the latter, so that an impaction of one inch may be secured easily. Greater shortening may be obtained by cutting off a portion of the shaft before performing the impaction.

#### *The Restoration of Walking.*

To enable the patient to stand and walk with or without crutches and apparatus is the ultimate aim of the whole treatment. The foot can always be stabilized and made plantigrade, the knee can always be fixed or controlled by tendon transplantation, and the hip brought down to full extension, whilst the two legs are made the same length by building up the short or cutting down the long leg. Then the critical question will arise as to the function of the glutei muscles. If these are sound, then the patient should be able to walk without crutch support. But if they are paralysed it is almost impossible to replace their action by any spring or stay, and the patient must be dependent upon crutches. But even walking thus he is usually a cheerful and contented person, instead of being a more or less helpless derelict.

#### THE HOSPITAL PROBLEM.

This brief summary of the nature, course, and treatment of infantile paralysis will serve to prove the urgent necessity for the provision of special institutional care for these cases. A similar claim might also be made for other groups of surgical cases, such as tuberculous disease of bones and joints, and many cases of deformity—for example, club-foot, congenital dislocation of the hip, and septic arthritis. All these diseases have this in common—they are curable, but they require years for their treatment. They need to be treated by a team of men—physician, surgeon, mechanic, and physiotherapist—as well as by specially trained nurses, who shall do nothing else and shall not be taken away just as soon as they know their work. Further, fresh air and open-air hospitals with the maximum of sunshine are necessary for most, whilst from an economic point of view education must be provided during the prolonged treatment. Such open-air school hospitals have been springing up all over the country, chiefly as the result of individual philanthropy and enterprise. But very much more requires to be done in a national and systematic method, if the problem is to be efficiently dealt with. Every large city and every county has now many agencies which provide hospital treatment for the sick, but these have arisen in a haphazard fashion, and for the most part without co-ordination one with another.

Unfortunately the general public of this country have been brought up to think that our voluntary hospital system is fundamentally good and that it should be preserved at all costs; and yet we, as medical men, know that it has failed. The evidence of its failure is only too evident to all who have eyes to see. The majority of voluntary hospitals, crippled by financial stress and governed by committees with a narrow and parochial outlook, fall very far short of the best Continental, Dominion, and American hospitals.

In the original meaning of the term there are very few voluntary hospitals left, for all are forced to ask for payments from their patients. The original idea of voluntary subscriptions has been overshadowed by a levy upon the patients themselves, by systematic collections from work-people or householders which almost amount to a tax, and by recourse to various lotteries and other gambling transactions, which can only be sanctioned by the doubtful morality, that the end justifies the means. But the most striking evidence of the failure of the voluntary system is found in the fact that every year a larger proportion of the sick have to be handed over to the Poor Law authorities. It is certainly an understatement of the case to say that more than half those who require hospital treatment cannot be taken by our voluntary hospitals, but have to find asylum in the Poor Law infirmaries. It is quite true that many of the latter institutions are good, modern, well equipped, well built hospitals. But they are understaffed as regards medical men, and especially as regards those of consultant rank. And quite apart from any comparison between voluntary hospital and the Poor Law hospital, the fact remains that we, as a community, are obliged to send half our sick to a State or municipal institution, and therefore it is fair to say that the voluntary system has failed. It is usual to pretend that the hospital difficulty is chiefly one of finance, and yet at the present moment we are told that a sum of no less than thirty millions has accumulated under the National Insurance Act and now awaits distribution. I suppose it is no use casting longing eyes upon this golden hoard, although it is tempting to suggest that it might be made the basis of a national fund for reorganization of our hospital system. I only refer to the matter to show that by a simple insurance system money can be had for all our hospital needs. It is not the want of money, but the want of willing co-operation between those who govern hospitals, that is the root of the difficulty.

At the present moment these cases of chronic illness, of which I have been describing one example, are the subject of many philanthropic societies and medical institutions, and yet as a whole they are treated very badly. In every large city there are "voluntary" hospitals, children's hospitals, a Poor Law infirmary, a city health committee,

and also perhaps an orthopaedic hospital and a crippled children's society; and yet in a great many there is no adequate system for treating cases of chronic illness requiring an open-air school hospital. A patient is operated upon in one hospital and then returns home to relapse; he is then taken to another hospital as an out-patient, where he attends until the expiration of his note; he drifts into the Poor Law infirmary, where he stays for a few years; he is befriended by the cripples' society, which sends him away into the country for a few months; or he comes to the health committee, which sends him away to a distant county, because this seems easier at the moment than the provision of efficient treatment at home.

It would seem so obvious that all those who are responsible for the treatment of the sick ought to co-operate instead of competing with one another. But this is apparently impossible because their independence would be threatened if each ventured to join hands with the others, even for the common good.

The Ministry of Health, one would have thought, would be the ideal agency to invoke to bring about hospital reform. But a Ministry will never take action until popular feeling is aroused, and the only way to arouse popular feeling is for the members of the medical profession, who know the facts, to explain them to the public.

It would seem to me that the essential needs of our long overdue hospital reform are as follows:

1. All hospitals should be controlled by a single committee of management in each county or administrative district. Each hospital would still require its house committee, but in matters of policy the interests of each institution would be subordinated to those of the community at large.

2. The financial basis of our national hospital scheme should be made worthy of this great and rich country, and the present jumble of municipal rate aid, State aid, haphazard philanthropy, and importunate begging or gambling should cease. National insurance should be the basis of hospital finance.

3. The treatment of all cases of chronic illness should be conducted in open-air school hospitals in the country.

At present only one political party, and that the socialists, have ever thought it worth while to formulate a hospital policy; and the socialists' policy is so identified with the idea of whole-time State service as to make it repugnant to the medical profession. But the essential ideals of hospital reform in no way necessitate this State service, and it is our duty to aim for these ideals in every way in our power, both in season and out of season.

## SOME FEATURES OF THE RHEUMATIC INFECTION.

BY

MARY BERTRAM, M.B., CH.M.

(From the Medical Department, Royal Hospital for Sick Children, Glasgow.)

The following investigation was undertaken in order to gain information regarding (1) the life-history of the rheumatic infection in childhood, and (2) the effect of different methods of treatment of the first rheumatic manifestation. The analysis was made from the records of 141 cases of rheumatic infection which had been admitted to the Royal Hospital for Sick Children, Glasgow, between the years 1916 and 1921 inclusive. In 1923 the cases were traced, those available were examined, and their histories subsequent to dismissal from hospital obtained.

The period between the onset of the first rheumatic manifestation and the final examination varied from one to eleven years; in 20 cases the period was under three years, in 93 between three and seven years, and in 23 cases between seven and eleven years. Since their dismissal from hospital the majority of the children had been leading ordinary home lives and receiving no special care or treatment.

### Manifestations of the Rheumatic Infection.

The following lesions have been considered as indicating rheumatic infection: (1) arthritis, (2) chorea, (3) carditis, (4) subcutaneous nodules, (5) tonsillitis, (6) cutaneous lesions—namely, psoriasis, erythema nodosum, erythema multiforme, purpura, and urticaria (these are only included when developing in cases with some other rheumatic manifestation).

### First Rheumatic Manifestation.

The relative frequency of the different manifestations during the first definite rheumatic attack is shown in the following table. As it is impossible, except from physical examination, to gain exact information regarding the presence of carditis, it cannot be said how often this was present as a first manifestation, and hence in the table cases of carditis associated with any other rheumatic manifestation have been omitted.

TABLE I.—Relative Frequency of Various Rheumatic Manifestations during First Attack.

Rheumatic Manifestation.	Cases.	Percentage.
Arthritis . . . . .	79	56.0
Chorea . . . . .	35	25.0
Carditis without other lesion . . . . .	10	7.0
Tonsillitis . . . . .	7	5.0
Arthritis + chorea . . . . .	5	3.5
Arthritis + tonsillitis . . . . .	5	3.5

### ARTHRITIS.

Though in the whole series of cases cardiac mischief occurred slightly more frequently as a manifestation of the rheumatic infection than did implication of the joints, arthritis will be considered in the first instance, not only because it occurred much more frequently as the first manifestation, but also because it is usually looked upon as the most characteristic of the various lesions. Arthritis occurred at some stage of the disease in 103 cases—that is, 73 per cent. of the total 141 patients. In 89 cases it was the first manifestation, but followed chorea in 10 cases and tonsillitis in 4 cases. It showed in addition a strong tendency to recur, 41 per cent. of the 103 cases having had four or more attacks, 6 per cent. three attacks, and 20 per cent. two attacks. In only 33 per cent. of the cases was there no recurrence.

**Age of Onset and Sex Incidence.**—No case of arthritis was recorded during infancy. One occurred during the second year, two during the third, and two during the fourth; 10 cases (10 per cent.) were under 5 years of age, 63 cases (61 per cent.) were from 5 to 10 years, and 30 cases (29 per cent.) were over 10 years of age at the onset of the first attack; 62 of the patients (60 per cent.) were girls and 41 (40 per cent.) boys, giving a ratio of 1.5:1.

**Seasonal Incidence.**—Although developing at all periods of the year, arthritis showed a definitely greater prevalence during the autumn and winter months. October and November were responsible for the onset in 32 per cent. of the total cases, while only

10 per cent. commenced during June and July (see chart). In Nordgren's series of cases for Stockholm the greatest number likewise occurred in October and November. In London, on the other hand, rheumatic arthritis would appear to be most common in September and October,<sup>2</sup> or May and November,<sup>3</sup> while

American figures<sup>2,4</sup> reveal the greatest prevalence during the first four or five months of the year.

**Associated Lesions.**—Arthritis was seldom the only manifestation of the infection. Only 6 cases gave no history, either previously or subsequently, of any other manifestation. The frequency with which other rheumatic lesions were associated with arthritis was as follows: with carditis 87 cases (84 per cent.); chorea 45 (44 per cent.); tonsillitis 32 (31 per cent.); nodules 10 (10 per cent.); and skin lesions 6 (6 per cent.).

#### CHOREA.

Authors differ in their opinion regarding the relative frequency of rheumatic and non-rheumatic chorea. For the purpose of the present investigation I selected all the cases of chorea from the hospital records, and in the series of 67 cases 50, or 75 per cent., presented at the time of the first observation, or gave a history of, some other manifestation indicative of the rheumatic infection. These 50 cases had all been classed "rheumatic" chorea, whereas the remaining 17 had been provisionally diagnosed "non-rheumatic" chorea. When, however, the latter group of 17 cases was reinvestigated in 1923, at periods varying between one and a half and six years after their dismissal from hospital, it was found that 9, or 53 per cent., of them had developed some manifestation definitely justifying their inclusion in the rheumatic series. Carditis had developed in 6 cases (35 per cent.), arthritis in 5 cases (29 per cent.), tonsillitis in 3 cases (18 per cent.), and skin lesions in 3 cases (18 per cent.).

Since the freedom from some subsequent rheumatic manifestation in the remaining 8 cases would seem to be due to the method of treatment adopted, rather than to any other factor (as will be revealed later when discussing the question of therapy), and since the vast majority of the children gave a history indicative of rheumatism, one feels, with Thomson,<sup>6</sup> "that it is well to regard every choreic patient as probably rheumatic and to be ready to treat him accordingly."

**Chorea as a First and Subsequent Manifestation.**—It is remarkable that when chorea did occur it most frequently developed as the first rheumatic manifestation. In 40 of the 67 cases it occurred as a first rheumatic manifestation; in 19 cases it followed arthritis and carditis, in 4 arthritis and tonsillitis, in 3 tonsillitis, and in 1 pericarditis. Noteworthy, too, is the fact that recurrences were not infrequent: 35 per cent. of the children had suffered from four or more attacks, 10 per cent. from three attacks, and 21 per cent. from two attacks. It is interesting to note the increase in the incidence of the various rheumatic manifestations in the total series of cases of chorea between the time of their coming first under observation and that of the final examination in 1923. During this period the percentage of cases presenting a cardiac lesion had risen from 54 to 70; arthritis from 57 to 64; tonsillitis from 25 to 30; and skin lesions from 1.5 to 6. There did not occur, however, any increased incidence of subcutaneous nodules, which still remained at 7 per cent. This is probably accounted for by the fact that by the time nodules appear the patient has usually passed through the whole gamut of rheumatic lesions.

**Age of Onset and Sex Incidence.**—No example of chorea was recorded under 3 years of age. In three cases it developed during the fourth year, in three during the fifth year, and in six during the sixth year of life; 18 per cent. of the patients were under 6 years of age; 55 per cent. were between 6 and 10 years; and 27 per cent. were over 10 years when they first suffered from chorea. This age incidence accords with that described by previous workers. Fifty-one of the cases were girls and 16 were boys, giving a ratio of 3:1.

**Seasonal Incidence.**—The seasonal incidence of chorea was remarkably similar to that of arthritis. November and February were the months showing the greatest prevalence, together accounting for 32 per cent. of the cases, while May and June were responsible for only 7 per cent. (See chart.)

**Lesions Associated with Chorea.**—Chorea was associated with other rheumatic manifestations in 59 cases, the most frequent from personal observation being carditis. Though chorea has been described by other writers as running concurrently with arthritis, such has not been noted in our cases. True, in the histories of some of the patients this had been recorded as having happened previous to their admission to hospital, but the association of chorea and arthritis was never observed while the patients were under our direct observation. We have seen one case, however, in which arthritis developed immediately after the cessation of chorea.

#### CARDITIS.

All cases of organic heart disease are considered under this heading, whether the pericardium, the myocardium, or the

endocardium was specially involved. Of the total 141 cases 107 (76 per cent.) had a cardiac lesion of some nature.

**Carditis as a Primary Rheumatic Manifestation.**—As many of the patients were not under observation during the first attack of rheumatism, it is impossible to determine accurately how frequently there had been cardiac involvement from the beginning. The fact, however, that 58 per cent. of 83 cases admitted to hospital during the primary attack did present a cardiac lesion would seem to indicate that the heart is often affected early in the course of the disease.

**Carditis as a Subsequent Manifestation.**—We had, however, frequent opportunities of observing the development of carditis subsequently to some previous rheumatic affection. For example, 46 cases either observed with arthritis or chorea, or giving a history of arthritis and chorea, were dismissed from hospital after their first period of residence without any evidence of cardiac implication, but at the time of the final review in 1923, 12—that is, 26 per cent. of these so-called "potential cardiac cases"—were found to have developed some heart lesion. The details regarding the above-mentioned cases are summarized in Table II.

TABLE II.—Subsequent History of Three Groups of "Potential Heart Cases."

Rheumatic Manifestation.	No. of Cases Without Carditis on Dismissal by time of (916-21).	No. of those who had Developed Carditis on Final Examination in 1923.
A. Arthritis ... ..	15	1 = 7 %
B. Arthritis and chorea ... ..	14	6 = 43 %
C. Chorea ... ..	17	5 = 29 %
		12 = 26 %

Although in the total series of cases (141) studied carditis was more frequently associated with arthritis than it was with chorea, the after-history of these potential cardiac patients shows (see Table II) that carditis had more frequently developed in those who had been in hospital on account of chorea than in those who had been treated for arthritis—for example, 7 per cent. of the latter as against 35 per cent. of the former. This apparently paradoxical finding we are in the meantime inclined to explain on the ground of the varying methods adopted in treating the examples of chorea. Without exception, all examples of arthritis were treated with salicylates, whereas in only a proportion of the cases of chorea was this line of treatment adopted, and, as will be shown later (p. 499), the incidence of subsequent cardiac disease in chorea was least in those who had been submitted to a course of salicylates. St. Lawrence,<sup>6</sup> in a recent study of his clinical material, also elicited the fact that cardiac disease is more frequent after chorea than after arthritis. In no case of arthritis did he find later affection of the heart, whereas in 39 per cent. of his patients suffering from chorea subsequent examination revealed a cardiac flaw. St. Lawrence, however, gives no details regarding the method of treatment adopted in the cases of chorea, and it is therefore not improbable that the high incidence of cardiac disease, which he also found following chorea, may be due, as in our series, to the neglect of specific antirheumatic therapy.

**Age of Onset and Sex Incidence.**—Because, as previously mentioned, many of the cases when first seen already presented evidence of a cardiac lesion, it was seldom possible to have any but an approximate idea of the age at which carditis developed. The youngest case observed with a definite cardiac lesion was aged  $\frac{3}{4}$  years; 14 per cent. of the children were under 6 years; 61 per cent. were between 6 and 10 years; and 25 per cent. were over 10 years of age when the cardiac mischief was first observed. Sixty-three of the cardiac cases were girls and 44 boys, giving a ratio of 1.4:1, which is practically the same ratio as obtained in the series of cases of arthritis.

**Lesions Associated with Carditis.**—Of the 107 cases with carditis 100—that is, 93.5 per cent.—presented, or had suffered from, some other rheumatic manifestation. In only 7 cases had there been no other evidence of the rheumatic infection, but not one of these gave a history of any other disease—for example, scarlet fever, diphtheria, or influenza—to which the cardiac lesion might be attributed, and we have therefore considered them as most probably rheumatic in nature. The relative frequency with which the other manifestations were associated with carditis was as

follows: with arthritis, 87 (81 per cent.); with chorea, 41 (44 per cent.); with tonsillitis, 25 (23 per cent.); with nodules, 10 (9 per cent.); and with skin lesions, 5 (5 per cent.).

*Frequency of Various Cardiac Lesions present.*—The following table (No. III) shows the relative frequency of the various lesions or combination of cardiac lesions and the frequency with which the different structures were affected.

TABLE III.—Showing the Relative Frequency of Various Lesions or Combinations of Cardiac Lesions Present.

Cardiac Lesion.	Cases.	Percentage.
Mitral incompetence ... ..	43	44
Mitral stenosis and incompetence ... ..	35	32
Pericarditis, mitral stenosis, and incompetence ...	5	5
Aortic incompetence and mitral incompetence ...	5	5
Aortic incompetence, mitral stenosis, and incom-	3	3
petence		
Pericarditis, aortic incompetence, mitral stenosis,	3	3
and incompetence		
Pericarditis, aortic incompetence, and mitral in-	2	2
competence		
Pericarditis and mitral incompetence ... ..	1	1
Mitral, aortic, and tricuspid incompetence ...	1	1
Mitral, aortic, and pulmonic incompetence ...	1	1
Mitral stenosis ... ..	1	1
Pericarditis ... ..	1	1
Hypertrophy and dilatation ... ..	1	1

*Frequency with which Various Structures were Involved.*—Mitral valve, 105 cases (98 per cent.); aortic valve, 15 cases (14 per cent.); pericardium, 12 cases (11 per cent.); tricuspid valve, 1 case (1 per cent.); pulmonic valve, 1 case (1 per cent.).

*Result of Cardiac Involvement.*—The all-important point in carditis is, of course, the degree of disability resulting. It is this which imparts to the rheumatic infection its seriousness and which has aroused the present almost world-wide interest in the subject. Of the 107 cases of carditis 28 had died by the time of the review of the material in 1923, but there were available for investigation and estimation of the resulting disability 79 children. Of these 79 children 9, or 11 per cent., were incapable of following any occupation or attending any other than a special school; 57, or 73 per cent., were leading moderately active lives, but gave a history of precordial pain or dyspnoea after exertion; and 13, or 16 per cent., were entirely free from any symptoms of cardiac disease.

*Nature of Lesion.*—In Table IV the results are summarized and classified according to the nature of the lesion present. As is to be expected, since of all rheumatic cardiac lesions that of the mitral valve is the most frequent, more had died and a greater number were markedly disabled through mitral disease than either aortic or pericardial mischief, but proportionately, aortic disease and pericarditis were much more serious lesions: 67 per cent. of the cases of pericarditis died, 47 per cent. of those with aortic disease, and only 17 per cent. of those with simple mitral disease. One was astonished that comparatively few of the cardiac patients were greatly disabled, the great majority of those living being only slightly inconvenienced. An equal proportion of both the mitral and aortic cases were devoid of any disability, but all the examples of pericarditis presented some symptom of cardiac distress.

TABLE IV.—Result of Cardiac Lesion Classified according to Structure Involved.

Lesion.	Total No of Cases	Died.		Markedly Disabled.		Slightly Disabled.		Not Disabled.	
		No.	Per cent.	No.	Per cent.	No.	Per cent.	No.	Per cent.
Mitral alone	84	14	17	8	9	51	61	11	13
Aortic	15	7	47	—	—	6	40	2	13
Pericarditis	12	8	67	1	8	3	25	—	—

In the following table (No. V) are summarized the results in the cardiac cases which have been grouped according to the age of onset of the first rheumatic attack, and from this

it is seen that on the whole the earlier the age of onset the greater the tendency to a fatal issue or marked disability.

TABLE V.—Prognosis in Relation to Age at First Rheumatic Attack.

Ago at First Attack.	Deaths.	Marked Disability.	Slight Disability.	No Disability.
	Per cent.	Per cent.	Per cent.	Per cent.
3-5 years ... 13 cases ...	22	11	55	11
5-7 " ... 32 " ...	41	9	41	9
7-9 " ... 21 " ...	26	10	52	13
9-11 " ... 25 " ...	12	4	63	15
11-13 " ... 11 " ...	18	9	55	18

Analysis of the fatal cases reveals the fact that death occurred in the great majority of instances comparatively soon after the inception of the infection. Of the 28 patients who died, the fatal issue ensued within three months of the onset of the symptoms in 7=25 per cent.; within one year in 16=57 per cent.; and within two years in 21=75 per cent.

#### SUBCUTANEOUS NODULES.

In marked contrast to their prevalence in some previously published reviews—for example, those of Still<sup>7</sup> and Poynton and Paine<sup>8</sup>—subcutaneous nodules were noted in only 10 (7 per cent.) of our cases. They developed during the first attack of rheumatism in 4 cases, during the second attack in 4 cases, and during the third attack in 2 cases.

*Age of Onset and Sex Incidence.*—One case was under 6 years of age, 3 cases were from 6 to 10 years of age, and 6 were over 10 years when the nodules were first observed. Seven of the patients were girls and three boys.

*Associated Lesions.*—In all the patients some other rheumatic manifestation was present. All 10 cases had carditis, and all had, or had had, arthritis, while 5 also gave a history of chorea and 2 of tonsillitis.

*Prognosis.*—It is generally agreed that this manifestation is of grave significance, indicating the presence of serious and progressive cardiac disease, and pointing to "lowered power on the part of the cells to destroy the infective agent."<sup>9</sup> It proved so in our cases, 60 per cent. of whom died, while the rest presented marked cardiac disability.

#### TONSILLITIS.

The opinion is general that there exists a definite and frequent relationship between tonsillitis and rheumatism, and recent writers from America<sup>9</sup> have stated that tonsillectomy more than any other measure prevents recurrence of arthritis and chorea. In the present series of cases under review, however, a history of sore throat was only obtained in 39=28 per cent. In only 7 cases did tonsillitis precede any rheumatic manifestation. In 5 cases it occurred simultaneously with some other manifestation, while in 13 it followed arthritis, in 10 arthritis and chorea, and in 4 chorea.

#### CUTANEOUS LESIONS.

Psoriasis, urticaria, erythema multiforme, erythema nodosum, and purpuric erythema have all been considered of rheumatic significance by many writers. Recently, however, their association with rheumatism has been questioned, and it seems doubtful whether these cutaneous affections occur with greater frequency among "rheumatic" patients than among those with other infections. In this series cutaneous lesions developed in only 8 cases (7 females and 1 male)—that is, 6 per cent. of the total 141 cases. Psoriasis occurred in 2 cases, erythema multiforme in 2 cases, erythema nodosum in 1 case, and urticaria in 3 cases.

#### EFFECT OF TREATMENT.

Though undoubtedly prophylaxis is the ideal form of treatment, absence of definite knowledge regarding the etiology of rheumatism makes discussion of this aspect of the subject futile. However, when the infection once declares itself there would seem little doubt that heroic and efficient treatment is well worth while. This is well borne out by contrasting the after-results of the cases of arthritis and chorea which were treated during their first attack at home with those treated in hospital. In many cases the home treatment was nil, or rest in bed for varying periods with or without the administration of salicylates. So far

as the cases of arthritis admitted to hospital were concerned, the treatment consisted in routine rest in bed for eight to twelve weeks, and the administration of sodium salicylate in doses of 60 to 180 grains a day. No less attention was paid to the slight cases than to the severe, it being, in fact, considered more important to treat efficiently cases of chorea or arthritis without cardiac involvement than those in which damage to the heart had already occurred. In these groups of cases reference is only made to the treatment of the first rheumatic attack. The results are summarized in Table VI.

TABLE VI.—Results of Home Treatment and Hospital Treatment of Arthritis and Choreia Contrasted.

Predominant Rheumatic Manifestation.	Cases Treated at Home during First Attack.		Cases Treated in Hospital during First Attack.		
	No. of Cases Treated.	No. who Developed Carditis.	No. of Cases Treated.	No. Admitted without Carditis.	No. of latter who Developed Carditis.
Arthritis ...	32	19 = 91 %	33	12	1 = 8 %
Chorea ...	46	34 = 74 %	21	13	5 = 38 %
Total ...	78	63 = 82 %	54	25	6 = 24 %

In contrasting these results it must be admitted, of course, that of the cases treated at home it would only be those in whom some serious rheumatic lesion subsequently developed who would come under further observation, and this naturally would raise the percentage of bad results in the home cases. The contrast, however, between the two groups is so marked that the benefit of thorough treatment in hospital cannot be gainsaid. While of the hospital cases of arthritis only 8 per cent. subsequently developed carditis, 91 per cent. of the home cases, on the other hand, suffered later from heart disease. The same difference, but to a less extent, is observed in the case of chorea, 38 per cent. of the hospital cases as against 74 per cent. of the home cases presenting later a cardiac lesion.

The greater tendency to the development of a cardiac lesion after chorea than after arthritis has already been referred to, and has been remarked upon by other writers. A critical analysis of our material strongly suggests that the tendency or otherwise for chorea to develop carditis depends on the type of treatment which has been adopted. Various are the methods currently recommended for the treatment of chorea, and in the cases under review most of the usual methods had been employed. Salicylates were administered in all cases who had recently suffered from arthritis. In the absence of any such history the patients were treated by arsenic, sedatives, or merely rest in bed without drugs. Rest in bed without drugs was reserved for the very mild cases, while sedatives were given in those examples characterized by violent jerking.

The relative values of the different methods in preventing cardiac disease are shown in Table VII, which details the

TABLE VII.—Relative Values of Different Methods of Hospital Treatment of Choreia.

Treatment.	No. of Cases Dismissed without Carditis.	No. who Subsequently Developed Carditis.
Arsenic alone ...	5	0 = 0 %
Arsenic + sodium salicylate ...	3	1 = 33 %
Arsenic + sedatives ...	1	1 = 100 %
Arsenic + sedatives + sodium salicylate ...	1	0 = 0 %
Sodium salicylate alone ...	4	0 = 0 %
Sodium salicylate + sedatives ...	1	0 = 0 %
Sedatives ...	3	2 = 67 %
Rest alone ...	5	3 = 60 %
Totals ...	23	7 = 30 %

subsequent cardiac history of all the cases of chorea treated in hospital and dismissed without any cardiac lesion. The cases of chorea who came under observation with carditis or developed carditis during the course of the illness have been purposely omitted from this analysis as being outside the point under discussion. Cases dismissed irregularly are also excluded.

The results appear more striking when summarized thus and render further comment unnecessary:

Of non-cardiac cases—

9 received salicylates and 11% subsequently developed carditis.
10 " arsenic " 20% " " "
6 " sedatives " 50% " " "
5 " rest only " 60% " " "

It might, of course, be argued that as sedatives were given in the cases with the most violent choreiform movements they had been employed in the most severe examples of the infection, but a review of all the cases of chorea did not disclose any relationship between the severity of the movements and the incidence of cardiac involvement. Another possible fallacy in the above results seemed to be the use of rest alone in the very mild cases. It might be suggested that the milder examples of chorea came under observation at a later stage of the disease, and thus there had been greater opportunities for the development of cardiac complications, but from a careful scrutiny of the histories it did not appear that the mild cases had been admitted to hospital any later in the course of the disease than those severely affected.

One feels justified, therefore, in concluding that it was the difference in the methods of treatment adopted that was responsible for the variation in the above results. Other drugs may be equally or even more effective in temporarily checking the choreiform movements and in overcoming the emotional disturbances; but if we regard every case of Sydenham's chorea as a manifestation of "the rheumatic infection," and thus a potential cardiac case, treatment by any other method than by the administration of salicylates seems wholly unjustifiable.

SUMMARY.

1. The records of 141 cases of rheumatic infection are analysed.
2. The patients were examined one to eleven years after the first attack.
3. No case occurred during infancy; 60 per cent. were from 6 to 10 years of age at the onset of rheumatism.
4. Girls were affected more frequently than boys. The disproportion was most marked in the case of chorea (3:1).
5. Arthritis was most prevalent in October and November (32 per cent.), chorea in February and November (32 per cent.).
6. As regards the lesions considered in this paper, 76 per cent. had carditis, 73 per cent. arthritis, 47 per cent. chorea, 28 per cent. tonsillitis, 7 per cent. subcutaneous nodules, 6 per cent. skin lesions.
7. With regard to cardiac involvement—6 per cent. had marked cardiac disability, 41 per cent. slight disability, 9 per cent. carditis without disability, 24 per cent. had no cardiac involvement.
8. Of the total cases 20 per cent. died; 25 per cent. of the fatalities were within three months, 57 per cent. within one year, 75 per cent. within two years from the onset of rheumatism.
9. Pericarditis and subcutaneous nodules were the lesions indicating most severe infection.
10. Early hospital treatment diminished the incidence and severity of carditis.
11. Treatment was more effective in preventing carditis in arthritis than in chorea.
12. Cases of chorea treated by sodium salicylate had a lower incidence of subsequent carditis than cases treated by arsenic, sedatives, or rest without drugs.

In concluding I have pleasure in expressing my thanks to Dr. Leonard Findlay for placing the material for this work at my disposal, and for his helpful criticism and encouragement.

## OVARIAN TUMOURS COMPLICATING PREGNANCY, LABOUR, AND THE PUERPERIUM.

(Additional Cases.)

BY

HERBERT R. SPENCER, M.D., B.S., F.R.C.P.,  
OBSTETRIC PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL.

In the Lettsomian Lectures<sup>1</sup> delivered before the Medical Society of London in 1920 I published the whole of my experience of ovarian tumours complicating pregnancy, labour, and the puerperium. The following cases have occurred since, and I now publish them in order to complete the series up to date.

The first series of cases, 55 in number, was attended by the death of one mother (from intestinal obstruction); the present series, 8 in number, was also attended by one death (from pulmonary embolism on the twenty-fourth day). The mortality for the 63 ovariectomies was 3.1 per cent.

## CASE 56.

Mrs. M., aged 27, pregnant for the first time (married on August 27th, 1919), was sent to me by Dr. Fenis on February 7th, 1920. She had been last "unwell" three weeks previously, when she only had a pink discharge. She had never gone over her time. The pelvis was large (iliac spines 11 in., iliac crests 11½ in., external conjugate 8½ in.). The breasts resembled those of pregnancy. The uterus could be felt

at a height of 3 inches above the pubes. A tumour larger than a hen's egg could be felt behind and to the left of the cervix, which had the characteristic consistence of pregnancy. On March 19th the uterus had increased to the size of the organ at the fourth month, reaching up 4½ inches above the pubes. On May 19th the pelvic tumour had increased in size, being nearly as large as an orange, add was deep in Douglas's pouch; it felt hard like a fibroid and could not be pushed up.

On August 11th, 1920, I performed Caesarean section through an incision to the right of the middle line. The placenta was in front. The child (a boy weighing 7½ lb.) was delivered by the feet, and cried at once. The uterine wound was sewn up with silk sutures. The tumour was found to be a parovarian cyst of the right side. It measured 4 by 3 by 2½ inches and was removed (without the ovary and tube) by enucleation, after carefully tying all the vessels running in the cut peritoneum with fine silk, as also the small sheaf of vessels running towards its base, and then closing the peritoneum with fine silk. The cyst contained clear fluid of lower specific gravity than 1000, no solid growth or papilloma.

The patient made a simple recovery for a fortnight after the operation, when thrombosis of the right femoral vein occurred, which kept her in bed for a month. She made a good final recovery, and with her child was quite well three years later.

## CASE 57.

E. D., aged 33, mother of seven children, was admitted to University College Hospital on December 6th, 1920, complaining of increase in the size of the abdomen since her last childbirth three and a half months before, when the tumour was present but caused no difficulty; she felt a dragging pain in the tumour, and suffered from a winter cough with expectoration in which no tubercle bacilli were found. A multilocular ovarian tumour was felt in the abdomen reaching up to a height of 4½ inches above the pubes. It was removed through a median abdominal incision on December 11th, 1920. The tumour weighed 6 lb. and measured 5 by 6 by

4½ inches. Under the microscope it was a pseudo-mucinous cyst - apillae, and some of the smaller cysts were the epithelium of which was lowhera ation lasted twenty-eight minutes. The bronchitis was aggravated by the operation; the temperature reached 102° on the third day. The patient left the hospital well on January 8th, 1921.

## CASE 58.

M. M., aged 34, who had had three children (no miscarriage), was admitted to University College Hospital on February 13th, 1922, complaining of pain in the right side of the abdomen since a week before her last child was born (two years and four months before). She was in the ninth week of pregnancy, having last menstruated on December 20th, 1921. A small cyst could be felt on the right side of the lower abdomen, and manually the uterus, nine weeks pregnant, could be felt, pushed over to the left side.

On February 18th, 1922, the tumour was removed through a Pfannenstiel incision. The wound healed by first intention and the recovery was simple, the highest temperature being 99.4° on the second day. The patient was delivered naturally of a living boy, after two hours' labour, on September 26th, 1922. In January, 1925, the abdominal wall was strong and the scar scarcely visible. The tumour measured 2½ by 2½ by 2½ inches; it was a lutein cyst of the right ovary.

## CASE 59.

N. A., aged 18, a primigravida, was admitted to University College Hospital on May 15th, 1922, as she had been found (on her previous admission in April) to have a dermoid tumour in the pelvis which could not be pushed up. The pelvic measurements were: iliac spines 10 in., iliac crests 11½ in., external conjugate 8½ in., diagonal conjugate 4½ in.; the outlet was contracted.

Caesarean section was performed on May 20th, 1922, two days before term. The child was delivered in fifty-three seconds; it weighed 7 lb. 6 oz., and cried at once. The ovarian tumour (of the right side) was then removed and the pedicle tied with silk, the tube being left behind. The operation lasted fifty-eight minutes. The patient made a good recovery, the highest temperature being 100° on the seventh day, afterwards normal. The tumour was a dermoid weighing 6½ oz., and measured 4 by 2-3/5 by 2 in. It contained cartilage, fat, muscle, spaces lined with epithelium, sebaceous glands, and hair follicles, and was lined with a thin squamous epithelium.

## CASE 60.

R. B., aged 34, mother of seven children (no miscarriage), was admitted to University College Hospital on May 25th, 1922. Her doctor had found a tumour in the abdomen during her last pregnancy, and while she was being prepared for admission to the hospital labour came on and she was delivered of a living child, which presented by the breech, on January 29th, 1921. She had steadily increased in size, and was again about five and a half months pregnant, having last menstruated on November 22nd. There was very extensive pigmentation of the arms and face. The uterus reached up to the umbilicus, and above it was a flaccid cyst extending up to the ensiform cartilage.

Ovariectomy was performed on May 27th, and a multilocular cyst of the right ovary containing blood-stained fluid was removed.

It was mainly unilocular with a few daughter cysts, and contained no solid growth except one or two small masses of papilloma showing under the microscope no tendency to malignancy. After the operation the pigmentation became less intense. A good recovery ensued; the highest temperature was 99.4°. She left the hospital on June 6th. The pregnancy continued, and the patient was delivered of a living girl on September 12th, 1922, and of a living boy in October, 1923.

CASE 63.—A=Operation. B=Deep stitches removed. C=Superficial stitches removed. D=Vomited. E=Death from pulmonary embolism, 7 p.m.

temperature during her stay in hospital was 99.4°. She left the hospital on June 6th. The pregnancy continued, and the patient was delivered of a living girl on September 12th, 1922, and of a living boy in October, 1923.

## CASE 61.

L. T., aged 30, mother of two children, was admitted on June 2nd, 1922, complaining of dragging pain in the left iliac fossa and of a yellow discharge since her last confinement five months before. She had had a flooding nine weeks before admission and had "seen nothing" since. The uterus was felt at a height of 2½ inches above the pubes, of the size, shape, and consistence of the pregnant organ at the ninth week. Behind the uterus could be felt a cystic swelling larger than a hen's egg; it could be moved but not easily pushed out of the pelvis.

Ovariectomy was performed by a median abdominal incision on June 4th, 1922. A good recovery was made; the highest temperature was 100° on the seventh day. The tumour consisted of a cyst measuring 2½ by 2½ in., with two small cysts in its wall, and of a more solid part containing a few small cysts and a corpus luteum of pregnancy. The patient went to term and was delivered of a living boy at the end of January, 1923.

## CASE 62.

M. K., aged 33, who had had two children and one miscarriage, was admitted on July 29th, 1922, complaining of flooding for nine days. The patient was two months pregnant. An ovarian tumour was found reaching up to within 1½ inches of the umbilicus. Next day the temperature reached 102.2°, and the patient passed a two-months ovum; the temperature then fell to normal. On August 1st the uterus was felt at a height of

OVARIOTOMY FOR TUMOURS COMPLICATING PREGNANCY, LABOUR, AND THE PUERPERIUM (EIGHT ADDITIONAL CASES).

No.	Initial.	Age.	Children.	Abortion.	Time of Discovery of Tumour.	Seat of Tumour.	Nature of Tumour.	Result of Labour to—		Growth of Tumour during Pregnancy.	Date of Ovariectomy.	Adhesions.	Result.

63	L.A.	31	0	0	During this pregnancy	R. parovarium	Unilocular cyst—3½ by 3½ by 2½ in.	Died	Died (Caesarean section after mother's death)	No	May 19, 1923 (at 31st week of pregnancy)	No	Died.*

\* Pulmonary embolism June 12th, twenty-four days after operation.

3 inches above the pubes; it was pushed forwards by a tumour, as big as a child's head, which was thought to be probably a dermoid. Ovariectomy was performed on August 5th. During the separation of an adhesion the tumour burst. It was removed and the pedicle tied with silk. The operation lasted forty-three minutes. The tumour was a multilocular pseudo-mucinous cyst containing unbranched papilloma; one more solid portion contained a loculus filled with branched papilloma. The patient made a good recovery (highest temperature 99.8°), and left the hospital at her own request on August 21st.

## CASE 63.

L. A., aged 31, married two years, applied when thirty-one weeks pregnant for a confinement "letter" at University College Hospital. She had suffered a good deal from vomiting in the morning and from headaches during the last few weeks. She had a feeling of weight on walking and was very breathless on exertion. The heart apex beat was in the fifth space 4 inches from the middle line, and, on auscultation, a systolic and a presystolic murmur were heard. The urine, specific gravity 1020, was free from albumin, sugar, or blood. The pelvic measurements were: iliac spines 9½ in., iliac crests 10½ in., external conjugate 7½ in. On May 18th the uterus reached up for 8 inches above the pubes. The child presented by the head. On vaginal examination a firm rounded tumour as big as a flattened orange could be felt in the retrouterine pouch. It was diagnosed as a dermoid.

Ovariectomy was performed on May 19th, 1923. The uterus was withdrawn from the abdomen through a ten-inch incision and the tumour brought up. It was a parovarian cyst, on the right side, measuring 3½ by 3½ by 2½ inches. The pedicle was tied with silk (without enucleating the cyst) and the raw edges sewn over with fine silk. The ovary was not removed. The operation lasted fifty minutes, under ether anaesthesia. The wound healed by first intention. The cyst was unilocular, contained clear watery fluid, no albumin, and no papilloma; it was lined by cubical epithelium. The patient made a normal recovery, the temperature never rising above 99.2° till the fifteenth and sixteenth days, when it rose to 100°, but fell to normal afterwards. On those two days the patient complained of sharp pain in the chest, but no physical signs could be detected, and the pulse was but slightly affected and the respiration not at all. On the twenty-first day the patient got up and lay on a couch, and on the twenty-second and twenty-third days she sat in a chair. On the twenty-fourth day she walked about the ward at intervals for half an hour; but on returning to bed she suddenly collapsed and rapidly lost consciousness and the breathing became stertorous. The pulse at first was full and bounding, then rapid and weak. There was considerable cyanosis and dyspnoea, and the right leg was found to be slightly swollen. The patient died in ten minutes from the onset of the attack. Caesarean section was performed by the obstetric registrar within three minutes after the death of the mother, but though the foetal heart was beating slowly the child never breathed, in spite of prolonged attempts at artificial respiration.

At the post-mortem examination the heart weighed 10½ oz.; there was slight excess of pericardial fluid. The right ventricle and conus were distended. The pulmonary artery and its two main branches were completely blocked by a cylindrical embolus 14 inches long. The embolus was coiled up in itself and extended through the pulmonary orifice for a short distance into the right ventricle; at one end it measured three-eighths of an inch in thickness and gradually tapered off towards the other end; it had a considerable branch from 2 to 3 inches from its thick end. The edge of the mitral valve was thickened; there was no fusion of the flaps and no shortening or thickening of the chordae. The stenosis was slight.

The lungs were congested and oedematous.

The pelvis and calyces of the kidneys and the ureters were moderately dilated. There was no pyelitis. In the cortex of both kidneys were scattered nodules of caseous material.

The inferior vena cava, the external and internal iliac veins, and the uterine and ovarian veins were normal and free from clot. Unfortunately the femoral veins were not slit up.

Of the eight cases now recorded one (Case 58) was operated on through a Pfannenstiel incision, the wound being closed with silk for the fascia and silkworm gut for the skin; the remaining seven cases were operated on through a longitudinal incision, and the wound was closed by through-and-through stitches of silkworm gut (tied over gauze), silk (continuous for the peritoneum and interrupted for the fascia), and silkworm gut for the skin. All the eight wounds healed by first intention.

In three of the cases there was a departure from the rules given in my Lettsomian Lectures.<sup>1</sup> Thus in Cases 56 and 59 Caesarean section was performed before the tumour was removed, and in Case 63 the tumour (a parovarian cyst) was removed at the thirty-first week of gestation. An improved technique in closing the uterine wound with silk, by which the formation of adhesions of any importance is avoided, inclines me to think that it may be employed more frequently in these cases than was formerly thought advisable. On the other hand, the tragic death of Case 63 causes me to regret having departed from the rule not to operate in the latter half of pregnancy until near term, or during or after labour.

*Parovarian Cysts Complicating Pregnancy, etc.*

Cases 56 and 63 were small parovarian cysts, in the pelvis. Of the former series, Cases 2, 46, 47, 48, 50, and 51 were also parovarian cysts; of these, Cases 48 and 50 were in the pelvis, and were delivered with difficulty by forceps, one child (Case 50) being born dead.

The recorded cases of parovarian cysts complicating pregnancy, etc., are few in number. Thus, in McKerron's classical work,<sup>2</sup> out of 1,290 cases only 9 were parovarian cysts; of these, six were removed in the third month and the patients went to term; two were removed in the fourth month and one (at least) went to term, although the pedicle was twisted; the ninth of McKerron's collected cases was removed in the sixth month and the patient was delivered prematurely. In Dsirne's<sup>3</sup> collection of cases there were only four parovarian cysts, and the tumours were removed in the fifth, third, fifth, and second months; three of the patients went to term, and one was delivered prematurely at the seventh month. Three out of his four cases had a pelvic abscess in the puerperium.

Of my own eight cases of parovarian cyst only four were seen during pregnancy. Of these, Case 2 was delivered of a living child by forceps, and the cyst was removed eight weeks later. Case 47 had a parovarian cyst of the size of an emu's egg; the pedicle had undergone torsion. It was removed two hours after the occurrence of the torsion at the thirteenth week of pregnancy, together with the ovary, which was infiltrated with blood. The patient aborted twelve days later, but has since had four children (two boys and two girls). This was the only case in which the ovary was removed. In Case 56 the cyst was removed immediately after Caesarean section at term, and thrombosis of the femoral vein occurred. In Case 63 the cyst was removed at the thirty-first week, and death occurred from pulmonary embolism on the twenty-fourth day.

A consideration of McKerron's (9), Dsirne's (4), and my own (8) cases leads to the conclusion that parovarian cysts, intrinsically so benign, have special dangers as a complication of pregnancy. From such a small number of cases it is impossible to establish rules of treatment, and it is greatly to be desired that those gynaecologists who have had a considerable experience will publish all their cases.

My present feeling is strong against the advisability of operating on these cases in the second half of pregnancy, except at term or during or after labour, and for parovarian cysts in the pelvis Caesarean section may be advisable, though rarely necessary for benign non-adherent ovarian cysts.

## TIME-SAVING METHODS IN DIABETIC URINALYSIS.

BY

FRANCIS TEMPLE GREY, B.A. OXON.,  
M.B. SYDNEY,

CHEMICAL PATHOLOGIST TO THE MINISTRY OF PENSIONS.

For the detection of reducing substances in the urine there exists no better test than Fehling's, provided care is taken to see that the amounts of urine and mixed Fehling solutions are equal and the whole raised just to the boil. The presence of glucose will, of course, in a new case showing a low percentage, be confirmed by fermentation with yeast in the Einhorn saccharimeter.

To determine the daily (twenty-four hours) output of glucose a fairly accurate saccharimetry is required, and if dealing with a large number of specimens it becomes necessary to do this quickly and economically. The following procedure has been found of use in the saccharimetry of some 2,000 specimens.

In the case of urine with from 0.1 to 0.5 per cent. glucose,

take 2 c.cm. 1 in 10 mixed Fehling's solution in a test tube and about 15 drops of Gerrard's reagent; heat, and as the mixture comes to the boil deliver the urine from a Dreyer pipette a drop at a time. (The advantage of the Dreyer pipette is that, held vertically, it drops very consistently—various pipettes differing very little—22 to 24, say 23, drops to the cubic centimetre, enabling the following simple table to be prepared.)

TABLE I.

Drops of Urine.	Glucose per cent.		Drops of Urine.	Glucose per cent.	
	Calc.	Approx.		Calc.	Approx.
5 ...	0.450	0.5	16 ...	0.144	0.1
6 ...	0.384	0.4	17 ...	0.135	0.1
7 ...	0.328	0.3	18 ...	0.127	0.1
8 ...	0.288	0.3	19 ...	0.121	0.1
9 ...	0.256	0.2	20 ...	0.115	0.1
10 ...	0.230	0.2	21 ...	0.109	0.1
11 ...	0.209	0.2	22 ...	0.105	0.1
12 ...	0.191	0.2	23 ...	0.100	0.1
13 ...	0.177	0.2			
14 ...	0.165	0.2			
15 ...	0.154	0.2			

Where less than five drops suffice to decolorize dilute the urine 1 in 5 and read as follows:

TABLE II.

Drops of Urine.	Glucose per cent.		Drops of Urine.	Glucose per cent.	
	Calc.	Approx.		Calc.	Approx.
5 ...	2.30	2.3	15 ...	0.77	0.8
6 ...	1.92	1.9	16 ...	0.72	0.7
7 ...	1.64	1.6	17 ...	0.67	0.7
8 ...	1.44	1.4	18 ...	0.63	0.6
9 ...	1.28	1.3	19 ...	0.60	0.6
10 ...	1.25	1.3	20 ...	0.57	0.6
11 ...	1.04	1.0	21 ...	0.54	0.5
12 ...	0.95	1.0	22 ...	0.52	0.5
13 ...	0.83	0.9	23 ...	0.50	0.5
14 ...	0.82	0.8			

If less than five drops of 1 in 5 urine decolorize, dilute 1 in 10, or (where the specific gravity exceeds, say, 1032) 1 in 20, and read as follows:

TABLE III.

Drops of Urine.	1 in 10 Urine.		Drops of Urine.	1 in 20 Urine.	
	Rough percentage Glucose.			Rough percentage Glucose.	
5 ...	5		5 ...	10	
6 ...	4		6 ...	8½	
7 ...	3½		7 ...	7	
8 ...	3		8 ...	6	
9 ...	3		9 ...	5½	
10 ...	2½		10 ...	5	

At these percentages many will prefer to do a formal titration or to use the polarimeter. (Gerrard's reagent is prepared by decolorizing boiling mixed Fehling's solution by means of a 5 per cent. solution of potassium cyanide delivered from a burette.) The polarimeter will nearly always give a lower reading than titration, owing to laevorotatory substances. If it is desired to express this as haerulose, multiply the difference by 0.284. On more than one occasion I have found dextro- and laevo-rotatory substances present in such proportions (that is, as 28:72) as to give a zero reading in the polarimeter, as against 1 per cent. total reducing substance.

To arrive at the glucose output for the day, look up in Table IV the number of litres corresponding to the number of ounces reported by nurse or patient, and multiply by ten times the glucose percentage. Glucose having been found, ketone bodies are to be looked for. Rothera's test may be done as follows: Make up a batch of 2-gram packets of ammonium sulphate. For the test, empty a packet into a small porcelain dish—say, the bowl of a crucible—add about 2 c.cm. of urine, a few drops of 5 per cent. sodium nitroprusside, and then some strong ammonia. The sodium nitroprusside need not be made up fresh each time; keep in a brown well stoppered dropping bottle, shutting off after use. You will know if the solution goes off by its changing colour—first paling, and then turning green (owing to sulphur compounds in the air).

If Gerhardt's test is positive, the ammonia coefficient ought to be done. Gerhardt's test, it will be remembered, detects relatively considerable quantities of aceto-acetic acid by the cautious addition to the urine of a solution of

iron perchloride, when in a positive case a wine colour, paling considerably on heating (distinction from salicylates, etc.), will develop.

The time-saving method about to be described enables the ammonia coefficient to be determined as a routine if desired. Two data are required—the ammonia percentage and the urea percentage. The ammonia may be determined by Malfatti's method, only slightly modified as below, and the urea by the sodium hypobromite method, using, however, Hinds's modification of the original and unsatisfactory ureameter of Doremus.

In Malfatti's method the reaction of the urine is determined *en passant*, as it is first necessary to neutralize the urine. Proceed as follows: Deliver from a Dreyer pipette into the bowl of a small crucible ten drops of urine, and a drop of phenolphthalein, and from another Dreyer pipette deliver drops of decinormal alkali until the colour appears.

To determine roughly the ammonia for the purposes of the coefficient add now two drops of formalin to the neutralized urine—this will discharge the indicator colour—and proceed to add drops of decinormal alkali as before to reneutralization (when roughly each drop represents 0.02 per cent. ammonia). Table V shows at a glance the ammonia coefficient and will save much laborious calculation. An ammonia coefficient of 10 per cent. or more indicates danger of diabetic coma.

TABLE IV.—Converting Ounces into Litres.

Oz.	Litres.	Oz.	Litres.	Oz.	Litres.	Oz.	Litres.	Oz.	Litres.

## TREATMENT OF DIABETES BY RAW FRESH GLAND (PANCREAS).

BY

THOMAS J. HOLLINS, M.D.,  
CHESTERFIELD.

THERE are many theoretical objections to the use of raw pancreas by the mouth in the treatment of diabetes; the chief are:

1. That the internal secretion of the gland is destroyed and thereby rendered inert by the action of the gastro-intestinal ferments.

2. That the administration of raw gland by the mouth has been tried before in the treatment of diabetes, and has failed in the hands of careful observers.

3. That it is difficult to be certain that the right part of the gland is being administered when given by the mouth.

In spite of these and other objections the use of raw fresh gland has yielded such striking results during the two and a half years I have been using it that I think they are worth recording.

I find that raw gland seems to do all that insulin does in a diabetic case, while it is free from the grave risks attendant on the use of insulin (for example, hypoglycaemia). While so far I have not used it in a sufficient number of cases to claim that it is a complete substitute for insulin, the facts I have collected point in that direction. It renders the urine free from sugar within twenty-four hours of the initial dose; it lowers the blood sugar, and the ketone bodies disappear from the urine. This clearance in twenty-four hours has occurred in all cases in which the raw gland has been used. It has been found that if in the course of routine administration the gland is withheld the sugar constantly reappears in the urine.

The method used in the administration of raw gland is as follows:

The patient is first carefully dieted and kept at rest. If this fails to clear the sugar from the urine he is at once given raw gland and a diet arranged according to his weight and the type of work he has to do. The first essential is that the gland should be perfectly fresh. In this I think lies the explanation of the failure of other observers to obtain any useful results with raw gland. I found repeatedly that after keeping and heating the gland was useless; even if taken in large doses sugar invariably appeared in the urine of the patient. So that it seems probable that the internal secretion of the pancreas is a labile substance easily destroyed and rendered inert by heating and keeping.

In the second place it must be given raw, and is best given finely minced. Cooking in any degree renders it useless. The dose which I have usually given—more or less an experimental one—is one tablespoonful of the raw fresh gland substance daily; in one case I found that a tablespoonful every other day just kept the urine sugar-free, only a faint reaction being given on the "off" days. I am now beginning to try larger doses as I feel sure there is no risk of inducing a condition of hypoglycaemia with raw gland, as there is with insulin. The raw pancreas is obtained from the butcher, and whether it be that of sheep or ox or pig does not seem to affect the result.

The first case in which I tried the oral administration of raw fresh gland was in a panel patient, a man who was suffering from a severe form of diabetes, ketone bodies being present in his urine. This was in the summer of 1922, before the introduction of insulin. I first examined him in the spring of 1922, and after treating him for some time sent him into the local hospital. He was admitted and treated by a variety of diets (Allen and modified Allen, etc.), all of which signally failed to do him any good, and he rapidly became emaciated. He came back to me in June, and as an experiment I suggested to him that he should try a tablespoonful of raw fresh pancreas daily. The result was striking: his urine became rapidly sugar-free and he began to put on weight. After three weeks of gland treatment he felt so well that he returned to work, and has since held a responsible position as foreman engineer in an ironworks. Recently—that is, after a lapse of two and a half years—he visited me again, and I found him well nourished, and discovered that he was still carrying on the gland treatment; he informed me that he had not lost a day's work in the interim. I got his blood sugar tested, and found that it was 0.129 per cent.; his urine was sugar-free, but became loaded with sugar when I got him to stop taking the gland for a day or two.

In a number of other cases (about six in all) treated with raw gland by the mouth the same results were obtained. One case (a woman) is worth referring to, as she was treated with both raw gland and insulin, and a comparison of the results obtained seems to indicate that she did better on the former than on the latter.

This patient commenced gland treatment in the spring of 1924 and did very well. In June of that year I described my gland treatment to one of the honorary physicians on the staff of one of the Sheffield hospitals, and on my suggestion he admitted her to his wards so that gland treatment might be carried out under test conditions. Unfortunately, before she was seen by the physician in question an over-zealous house-physician gave her an injection of insulin, and this treatment she has carried on at home since her discharge from hospital.

Comparing her condition now (on insulin) with what her condition was in the spring of last year (on gland) I find that she has lost weight, does not feel so well, and some sugar is to be found in the urine.

These facts encourage me to think that raw fresh gland by the mouth is a substitute for insulin, and that it is a very much better form of treatment, as it is perfectly safe and free from the grave risks that may attend even a small dose of insulin; furthermore, it is less irksome to the patient and less troublesome to the doctor in charge—for all who have had much experience of insulin will agree, I think, that insulin treatment is both troublesome and irksome and fraught with considerable risk to the patient.

It may be objected that the eating of raw gland is a loathsome thing; but patients on gland treatment inform me that it forms quite a delicious meal, especially when taken with lettuce—reminding us in this respect of phthisical patients on raw or very much underdone meat, who tell us how difficult they find it to return to cooked chops and steak, which seem tasteless to them after being used for so long to the more palatable and tasty fare of raw meat.

## THE PREVENTIVE MEDICINE OF THE EAR.\*

BY

SOMERVILLE HASTINGS, M.S.LOND., F.R.C.S.ENG.,  
SURGEON TO THE EAR, NOSE, AND THROAT DEPARTMENT,  
MIDDLESEX HOSPITAL.

It is stated that a learned lecturer on surgery used to preface his lecture on diseases of the ear somewhat as follows:

"There are two kinds of deafness: One, the curable, due to wax, which we treat ourselves, and the other, the incurable, due to some other cause, which we send on to the specialist."

There is a good deal of truth in this statement, and it is certainly of value to inquire to what extent deafness, not due to obstruction in the external ear, can be influenced by treatment. That acute middle-ear deafness can be cured, sometimes with complete return to normal hearing, is within the experience of everyone; but can any real improvement in hearing result when the deafness is due to the chronic disease of the middle or internal ear?

Let us take the middle-ear cases first. They divide themselves naturally into the suppurative and non-suppurative. Where there is chronic suppuration in the middle ear this can in most cases be cleared up by treatment, but the perforation does not heal and the hearing but rarely improves, and not a few patients do not really thank one for drying up their ear, as they can hear better when it is moist. In middle-ear deafness without perforation of the drum, of the chronic catarrhal type and its many modifications, the outlook is, perhaps, a little more hopeful. In recent cases treatment of a septic focus in the nose, nasopharynx, or pharynx, or catheterization of the Eustachian tubes, may result in benefit to hearing, but the improvement is but rarely marked, while the results of treatment for internal-ear deafness are, I think, even more hopeless.

This does not mean, however, that we can do nothing for the sufferer, for though chronic deafness is very often

a progressive disease, it is also in many cases a disease that can be arrested. If we can induce a suppurating ear to dry up and cease to discharge and remain in this satisfactory condition, although no improvement in hearing may take place, any increase in deafness generally occurs very slowly. In cases of middle-ear deafness, also, without perforation or suppuration, much more can be done to arrest the disease than is frequently thought, though not to cure it. Some authorities are accustomed to label all cases of middle-ear deafness in which other members of the family have suffered in the same way, and where low pitched tuning-forks cannot be heard by air conduction, as oto-sclerosis, and, having made up their minds that oto-sclerosis is a progressive disease uninfluenced by treatment, to do nothing further for the patient. I do not for a moment deny the existence of the pathological changes described by Fraser, Gray, and others in connexion with cases of middle-ear deafness with the above symptoms, but I personally can recall only one case of middle-ear deafness in which the nose, nasopharynx, and ear drums appeared perfectly healthy and in which a clear history of previous trouble in these regions could not be obtained when carefully inquired for. A slowly progressive inflammatory process in the middle ear, started and maintained by some infection from the nose or nasopharynx, may apparently go on for years without giving rise to any appreciable deafness, and only when the region of the ossicular joints or the secondary membranes are involved may deafness come on. I feel, therefore, very strongly that even in cases where considerable deafness exists it is our duty to treat any septic focus that may be found, in the hope, not of appreciably improving the hearing, but of preventing further deterioration. Especially is the removal of nasal obstruction or sepsis likely to be of value in cases in which the hearing varies from day to day, or where immediate improvement in hearing follows the passage of a Eustachian catheter. I know quite well that there are some cases that nothing will touch, and have learned especially to fear patients with atrophic membranes, who hear better in a noise. A large proportion of these cases give a history of earache in childhood, and though, when seen, all infection of the nose and nasopharynx may have disappeared, I believe that a good many of them are the result of inflammatory trouble during the early years of life, and that in these cases, although the causative infection in the nose or nasopharynx has disappeared, the infective process still continues in the ears. If this type of case is excluded, my experience leads me to the conclusion that in a large proportion of cases of slowly advancing middle-ear deafness the disease may be arrested or its progress much retarded by dealing with a neighbouring septic focus. I can recall only one case in which I have had reason to regret operation for nasal obstruction in the case of middle-ear disease, but I can remember many in whom the history of deafness, both before and after operation, has made me wish I had operated sooner. In the much fewer cases of internal-ear deafness, where a cause can be assigned, it should, of course, if possible, be removed. I have thought that the progress of those cases due to sclerotic changes in the vessels has been retarded by the adoption of a purin-free diet and flushing out the system by drinking quantities of hot fluids, but it is difficult to be sure of this.

### THE PREVENTION OF DEAFNESS.

If the foregoing conclusions be accepted it must of necessity follow that since little or nothing can be done by way of treatment for deafness, except to arrest the progress of the disease, the right thing is to get hold of cases early and deal with the sepsis or other condition producing the trouble; or, better still, to deal with the cause even before the effect is produced. So that the whole art of medicine, as far as the ear is concerned, is preventive—by either dealing with the hygienic of the mouth, ear, nose, or throat, before any changes in the ears occur, or, if this is not possible, directly there is the slightest indication of the commencement of mischief in the ear.

It is most important to remember that, with the exception of tumours, practically all diseases of the ear are due to

\* Abridged from a lecture given before the Society of Medical Officers of Health.  
† Dr. Kerr Love states that about 1 per cent. of the school children of Glasgow have chronic suppuration of the ear. (*Diseases of the Ear in School Children, 1919*)

trouble elsewhere, and that in by far the greater number of cases the disease starts in the middle ear. Further, it must not be forgotten that in practically all cases of chronic middle-ear trouble, and in most acute cases, the ear disease is an extension of some chronic sepsis in an adjacent region, and even when acute otitis follows one of the exanthemata, that a septic focus is nearly always present. Hence, in middle-ear suppuration following recovery from the disease. To operate for mastoid disease without searching for a septic focus before discharging the patient is as foolish as to open an appendix abscess without searching for the appendix.

The results of careful attention to general hygiene, and especially to that of the mouth, nose, and throat, in preventing deafness is very striking, and it is noticeable how large a proportion of the working classes over the age of 30, who for the most part have had the misfortune to lack this in the past, have some impairment of hearing. Sir George Newman, in his annual report for 1923 as Chief Medical Officer of the Board of Education, tells us that the percentage of children found on routine inspection in London with defective hearing has during the last ten years been halved, and that in Cambridge and Exeter the results have been even more striking; but he hastens to add that while this satisfactory result has been obtained in connexion with children of school age, the proportion of children going to school for the first time at the age of 5 or thereabouts with ear disease has hardly changed at all. This clearly points, as do many other facts, to the necessity of dealing with the beginnings of disease in children below school age, and that it is imperative that the commencement of the disease should be recognized and the first preventive measures taken in the infant welfare centres or the nursery schools. Mastoid disease calling for operation is by no means rare in babies of less than 12 months, and I am of opinion that otitis media is much more common in infants than is generally supposed. I have seen babies with red inflamed drums apparently quite well and happy and but little disturbed by the condition. When an infant or young child persistently rubs his ear, or frequently rubs the back of his head on his pillow, it should be taken as an indication of some ear disease and a careful examination carried out; if adenoids are present they should be removed. The removal of adenoids even in a baby a few days old is a very simple matter, if the proper sized curette is made use of, and it is remembered that, since it is impossible to insert the finger into the nasopharynx of a babe, the curette must serve for both diagnosis and treatment. No anaesthetic is needed, and most babies are quite prepared to enjoy a meal within a few minutes of the little operation, and appear little, if at all, inconvenienced by it. In children who are old enough to tell us when they have pain, two complaints of earache should be sufficient to determine a careful examination for adenoids,\* and if they are present even in small quantity they should be removed. Whether the tonsils, unless obviously diseased, should be removed at the same time is a moot point, and all I would like to say here is that on several occasions in which I have removed adenoids only, the subsequent history has led me to regret that I did not remove the tonsils at the same time.

But we ought to be able to prevent ear disease without waiting for deafness, pain, or other ear symptoms. Babies who cannot take the breast or bottle properly usually have adenoids. These should be looked for and removed. Every child also with a running nose needs immediate treatment, for not only may this condition directly encourage the growth of adenoids, but also, possibly without the existence of adenoids at all, a chronic infection of the ear may result. In addition to general hygiene and a sufficiency of vitamin-containing food and fats, there are four points especially worth remembering in the prevention and cure of chronic rhinitis and its ear complications in children.

1. In visiting a number of nursery schools last year I was especially struck by the difference between the children in the open-air and indoor schools. Anything from 10 to

\* The examination of the nasopharynx of several hundred boys, aged from 9 to 16, by the mirror, has shown that some quantity of adenoids was present or had been removed in about 80 per cent.

40 per cent. of the children shut in rooms, even though some windows were open, had running noses, whereas in the open-air schools I saw but one or two. It is not always understood that open-air schools need not be very cold even in winter if an efficient system of heating is installed.

2. As soon as children are old enough they must be taught to blow their noses at frequent intervals. They should not pinch the nose with a handkerchief, but should hold the handkerchief a few inches below the nose and blow into this, at the same time blocking one or other nostril by a finger pressed on to the side of the nose. It is wonderful how early a child will learn this if carefully taught.

3. A little ointment composed of 1 to 3 grains of menthol and 2 to 8 minims of oil of eucalyptus to the ounce of vaseline, applied to the interior of the nose at bedtime, is often a very considerable help in keeping the nose clear and preventing discharge.

4. Constant nose-breathing must be insisted upon. It is but little good to operate for tonsils and adenoids for the prevention or treatment of middle-ear deafness unless at the same time the child is taught to breathe constantly through the nose. I have seen cases in which tonsils and adenoids have been completely removed, but in which the habit of mouth-breathing still remained, and in which the nose steadily progressed until this habit was got rid of. To cure children of mouth-breathing deep breathing exercises are very helpful. In these the mouth is kept constantly closed, both during inspiration and expiration, and breathing is carried on entirely through the nose. Children are still taught to breathe in through the nose and out through the mouth by some teachers. This is exceedingly harmful, for the following reasons: In the first place, it is quite clear that no one can breathe in and out through the nose unless the nose is fairly clear—that is, free from excessive secretion—but it is quite easy to breathe in through the nose and out through the mouth with the nose full of mucus, as each inspiration draws this material further back until it reaches the pharynx and is swallowed by the child. Inspiration is followed by expiration, after which there is a very short period of rest. At the conclusion of expiration with the mouth open the child finds itself in a position in which a definite muscular effort (that is, shutting the mouth) is required before starting the next inspiration; if it is to be a correct one. There is a strong tendency for the child to start the new inspiration, as he finished the previous expiration, with the mouth open. It is essential, therefore, that all breathing exercises should be carried out with the mouth closed the whole time. They should be repeated frequently rather than carried out for a longer period at less frequent intervals. At night a piece of 1-inch rubber adhesive plaster about 2 inches long can be placed vertically between the upper and lower lips, or a piece of thin rubber sheeting, such as dentists use, 6 or 8 inches long by 2 or 2½ inches wide, can be placed over the lips and tied tightly at the back of the neck by tapes at the four corners. In many cases, however, the cure of mouth-breathing cannot be carried out except by constant supervision of the child by someone whose business it is to remind him to close his mouth whenever it is seen open.

## PRACTICAL POINTS ON PELVIC PAIN.

BY  
A. E. CHISHOLM, F.R.C.S.Ed.,  
ASSISTANT, OBSTETRICAL AND GYNAECOLOGICAL DEPARTMENT, ROYAL INFIRMARY, DUNDEE.

At the December meeting of the Edinburgh Obstetrical Society Professor Rauken Lyle of Newcastle read a paper on pelvic pain in its relation to neurasthenia, which provoked certain thoughts in me which I here seek to set in order.

I gather that Professor Lyle finds many patients who complain of pelvic pain, and who may or may not be found to have some demonstrable pelvic abnormality—for example, a uterine displacement—but whose symptoms he ascribes to neurasthenia and not to anything abnormal found in the

pelvis on examination, and whom he treats on anti-neurasthenia lines, with favourable effect in a good proportion of cases. The paper raised much discussion and a considerable amount of good-humoured adverse criticism. I do not write this paper with a view to criticism.

I shall attempt no proper definition of the condition called neurasthenia, but perhaps, for the purpose of this paper, a sufficient working definition would be that neurasthenia is a state in which the vital processes (nervous, etc.) are working on a lower grade than their usual and proper standard. Thus a lack of balance is set up between the result required and the means of producing that result. To all appearance the organs may be perfectly healthy.

The question may be asked, Can pain be caused by this upset of balance alone? I think it is reasonable to suppose that such may be the case. We should hardly be aware that we have internal organs—heart, lungs, stomach, and so forth—because they should act so perfectly that no inconvenience is caused. But if the workings are with effort (that is, on the part of the vital processes), then surely it is to be expected that discomfort will be the result, and this, accentuated, may develop into actual pain, the tissues being healthy otherwise. It is just as in the case of a wheel rotating stiffly, or even with squeaking, if the oil has run dry. The wheel and its bearings are all right, but there is a lack of proportion between the rotations taking place and the amount of oil available for efficient running.

No doubt neurasthenia is accountable for much trouble even of an apparently localized sort, but one must not be guilty of making such a diagnosis too easily. It is a tempting diagnosis to make, for the word has an attractive ring about it—it sounds almost scientific—and it pleases the patient's friends and solaces the doctor's diagnostic conscience. But what of the poor sufferer, who all the time may be afflicted with a really painful organic disease?

The first advice I would offer is: Diagnose neurasthenia last of all, after carefully excluding all other possibilities, the doctor not confining himself to gynaecological possibilities. I would suggest two safeguards against the too hasty diagnosis of neurasthenia in cases of pelvic pain.

First safeguard: Examine such patients first of all without an anaesthetic in order to localize the pain and to estimate, as nearly as possible, its severity. In virgins a rectal examination should suffice, along with a careful abdominal examination instead of a vaginal one.

But, one may say, a neurasthenic patient is sure to make a fuss and complain of tenderness whether it is there or not. This may be so far true, but if the site and degree of tenderness are the same on more than one occasion, the circumstantial evidence will be strong in favour of an organic lesion. Also, I think the experienced examiner will seldom be deceived. I should say that a tenderness due solely to a neurasthenic state is not likely to be so intense nor so constant as a tenderness due to an organic lesion. This, however, may be a debatable point.

Having examined in this way and formed an estimate of the presence, site, and degree of tenderness, an examination under a general anaesthetic may then be made, if required.

Second safeguard: Examine for the presence of regional cutaneous hyperaesthesia. This is, in my opinion, of some value if positive for a given area in intelligent patients, but it is of little moment, probably, except as an adjunct to other methods of examination. This test, giving a negative result, may be considered as almost, if not quite, valueless.

The next point I bring forward about pelvic pain in women is that it is, in my experience, very much more common on the left side than on the right. I think this will be readily conceded by gynaecologists. There are certain anatomical conditions which would appear to explain this inequality.

(a) The presence of the pelvic colon on the left side may predispose to pain in three ways:

1. The loaded colon may sag down into the pelvis and lead to pain from dragging on the mesentery.

2. Overdistension of the pelvic colon may lead to colicky pains, especially if the faeces are large and

hard and tend to become impacted in the rectum. On the other hand, colicky pains in themselves are possibly more commonly complained of on the right side in the region of the caecum and appendix.

3. The loaded pelvic colon or rectum may cause direct pressure on the left ovary in a way in which the caecum is very unlikely to do on the right one, especially if the ovary is prolapsed into the pouch of Douglas, as is often the case in conjunction with retroversion or retroflexion of the uterus.

(b) Pelvic varicocoele. I believe this is a condition which is more common than is often supposed. It is not easy to diagnose from examination, as the veins are apt to empty when the patient is lying down. For the same reason it is not usually very marked when the abdomen is opened, especially if the Trendelenburg position is employed. If the condition is suspected from symptoms, it would seem wise to examine the patient per vaginam in the erect attitude, and preferably after she has been going about or standing for some considerable time.

One would expect pelvic varicocoele to be more common on the left side than on the right, since the left ovarian vein passes upwards to enter the left renal vein at right angles, there being no valve at the junction of the two veins. The right ovarian vein enters the inferior vena cava at an acute angle, the flow of blood in the two vessels being almost in the same direction. The orifice where the right ovarian vein joins the inferior vena cava is guarded by a valve. Thus there is more liability for backward pressure to take place on the left side than on the right.

Constipation, as well as anatomy, may be a predisposing factor in this condition of pelvic varicocoele, especially on the left side. An attempt must early be made to overcome constipation in cases of pelvic pain due to conditions (a) and (b).

We are now in a position to take a further step and consider certain lines of treatment which may be adopted. Let us suppose that the condition is something like this: The patient suffers from pelvic pain on one or other side, and this has lasted, in all probability, for several months at least. She has had drug treatment and her bowels have been attended to. Still the pain persists. It may be aggravated by menstruation, but not necessarily so. Examination without an anaesthetic elicits definite tenderness in one or other lateral fornix, the degree and site being unchanged to any marked extent on re-examination. An area of cutaneous hyperaesthesia corresponding to pelvic organs, such as ovaries, may have been mapped out. Such conditions as chronic appendicitis, ureteral stone, etc., have been ruled out. Neurasthenia has been carefully considered but has been excluded; or treatment for neurasthenia may have been unsuccessfully tried. Something must be done, as the patient is obviously suffering genuinely, and yet nothing but localized and persistent tenderness can be made out.

In such a case surely one is justified in recommending an exploratory laparotomy. After all, a bimanual examination is not always very conclusive. It is not a very fine test, and it varies in its acuteness with the skill and experience of the examiner, as well as with the condition of the patient—for example, as to adiposity and muscular resistance. So we open the abdomen and find things fairly normal. If there is some cystic condition of the ovary, such as a small luteal cyst, a partial resection of the ovary may be done, or follicular cysts may be punctured, although it is a question if they cause pain, as they are in so very many cases symptomless, being so common as to be hardly pathological when small. But if nothing at all is found to be abnormal, and yet one feels quite sure that the tenderness was definitely referable to tube or ovary of one side, can nothing be done? Are the alternatives only to close the abdomen and so give no relief to the patient, or to remove an apparently healthy ovary and tube, or ovary alone? I think a middle course may lead to success in at least a certain number of cases. At any rate, it may well be tried.

It seems reasonable to suppose that something of the

nature of neuralgia may at times attack the ovary, an organ well supplied with nerves.<sup>1</sup> If so, it is reasonable to treat such a condition in the same way as neuralgia elsewhere. If drugs have failed, then operate. The injection of alcohol would hardly be recommended for ovarian pain, but the nerve supply, or a considerable part of it, if not all, may be cut off by simply dividing the suspensory ligament of the ovary. This, of course, means division of the ovarian artery and vein too, but the ovary will still have a sufficient blood supply to keep up its nourishment, and, that being so, ovulation and endocrine secretion should not be interfered with, unless the division of its nerve supply should so far impair these functions, which is not likely.

This treatment would particularly apply if there were only one remaining ovary in a patient who had not reached the menopause. The pain must be relieved in some way, and the ovary must be spared if possible. On the left side the division of the ligament may serve to straighten out the pelvic colon and thus help the flow of contents. No claim to originality is made here for the idea of dividing the ovarian nerve supply, but the suggestion seems a practical and reasonable one, and therefore I emphasize it.

I should like, in conclusion, to stress the two points brought forward early in this paper:

1. Diagnose neurasthenia last of all, after excluding all likely causes of pelvic pain.

2. In cases of pelvic pain make it a rule to examine first of all without an anaesthetic, even if such is necessary for a full diagnosis afterwards.

## DIPLOPIA IN ENCEPHALITIS LETHARGICA.

BY

E. R. CHAMBERS, F.R.C.S.Ed., D.O.M.S.,

OPHTHALMIC SURGEON, BRISTOL ROYAL INFIRMARY; ASSISTANT SURGEON,  
BRISTOL EYE HOSPITAL.

THAT diplopia is one of the earliest symptoms of encephalitis lethargica is well known. The diplopia may, of course, be that typical of an involvement of one or more of the extrinsic ocular muscles and may occur with or without a manifest squint, but cases also occur in which the diplopia cannot be attributed to this cause. The patient in the following case is typical of many who, during a recent epidemic of encephalitis lethargica in this city, applied to the ophthalmic clinics for relief of the diplopia.

A girl, aged 19, complained of diplopia. Two evenings before seeing me she had headache and giddiness and felt sick; on the following morning she awoke with diplopia; it was very troublesome when looking at distant objects, but was hardly present at all in near vision. There was no drowsiness. The temperature was 101°. There was no history of any recent illness. Examination of the eyes showed no ptosis, no manifest squint; the pupils were normal in size, equal, and reacted to light and accommodation. The movements of both eyes were normal. Both optic discs and fundi were normal. Examination of the diplopia showed it to be homonymous, with erect images, the unusual feature being that there was no alteration in the relative positions of the two images in any of the six cardinal directions of gaze. The first examination was carried out with the candle at 3 metres from the patient; a second examination at 5 metres showed the two images to be further apart than they were when the examination was performed at 3 metres, but again their relative positions remained the same in the six cardinal directions of gaze. On approximating the candle to 2 feet from the patient the diplopia ceased to exist in any of the six cardinal directions of gaze.

This case could not have been one of paresis of any individual muscle, as there was no increase in the distance between the true and false images in the direction of action of any muscle; nor could spasm of accommodation produce this type of diplopia, as in this case the double vision would have increased as the object was brought nearer the patient and diminished the further it was removed.

The diplopia disappeared in a week from its onset and the patient made an uneventful recovery, for the time being at any rate. No convergent squint ultimately appeared, as has happened with some of the patients under observation.

It is probable that these cases represent a rather rare condition of paralysis of divergence. Dunnington<sup>1</sup> of New York describes in detail three exactly similar cases occurring in an epidemic of encephalitis, and Holden<sup>2</sup> one such case, but these writers would appear to consider the condition to be one of great rarity, whereas in our series of cases this type of diplopia was so common as an early symptom that we began to regard it as pathognomonic of the disease in this particular epidemic. Another interesting fact was that this type of diplopia, with giddiness and rise of temperature, were the only symptoms complained of, and that many of the patients showed no other symptom but made a rapid recovery. That we were dealing with encephalitis lethargica was clearly manifested by the fact that a few of the patients with these symptoms developed the more serious accompaniments of the disease at a later date.

Duane<sup>3</sup> points out that the power of divergence is an active as well as a passive movement, and is brought about by a simultaneous equal contraction of both external recti accompanied by a simultaneous equal relaxation of both internal recti. This complex action is controlled by a definite nervous mechanism, and the loss of power means an innervational disturbance and not a muscular defect. This mechanism is probably controlled by a centre situated close to the sixth nerve nucleus. This would explain the fact that these cases are often followed by convergent strabismus due to a sixth nerve lesion. In making a diagnosis, paralysis of divergence is easily confused with paresis of one of the internal or external recti muscles, but can be differentiated by observing that the diplopia does not increase in the direction of action of these muscles, and that the separation between the true and false images remains unaltered so long as the distance between the eyes and the object is kept constant.

## PAROXYSMAL TACHYCARDIA IN AN INFANT.

BY

J. L. O'FLYN, M.R.C.S., L.R.C.P.,

BARRY, GLAM.

IT will be of interest to record this case of paroxysmal tachycardia on account of the very early age of the patient, and because it is an outstanding example of the vast amount of distress a young child's heart will stand.

The patient was a female child, aged 8 months, and the attack lasted for eight days without cessation. The heart could at no time be counted, but was roughly estimated at somewhere about 200 to 300 beats to the minute. The onset of hepatic pulsation, Cheyne-Stokes breathing, and severe bronchitis during the illness all had apparently no detrimental effects on the recovery. The child is the youngest of a family of three, having been born quite normally and fed on the breast, and the breast alone, up to the time of the illness. She had been examined at the local clinic at about the age of 6 months, and was found to be a perfectly healthy, contented, and exceptionally well nourished baby. The mother and the other children are all quite healthy, and the former undoubtedly makes an ideal mother.

I was called to see the baby on a Thursday afternoon because the mother had become anxious about its condition during the previous night on account of vomiting and restlessness. The child had been ill the whole night, but the mother had concluded that she was tired by a journey into Cardiff and a long day out in the sun the day previous. The mother noticed that the urine had become scanty, the evacuations a trifle loose and green, and that there had been no desire for food; this was most unusual in a child who had been accustomed to be most hearty.

The baby, when I first saw it, was apparently in no serious condition; its cheeks were rosy, its breathing was natural, and it had all the appearances of a child who was in perfect health but who was apparently somewhat restless and irritable as the result possibly of an irritable tooth. The temperature was just 96°, but no pulse could be felt at the wrists. There was nothing to be discovered in its abdomen nor on rectal examination. The chest, as far as the lungs were concerned, was devoid of physical signs. The nervous system was normal, all the reflexes being present and

normal in response, but during the examination the child had one or two convulsive attacks of a very slight degree. On examination of the heart, however, it was found to be beating very forcibly and at such an extraordinary rhythm that it was impossible to count. There was, as far as one was able to make out, no valvular or muscular disease or deficiency.

On this evidence, the green stools, the convulsive attacks, and the extraordinary cardiac rate, I concluded that the child was suffering from intestinal irritation and toxæmia, and advised treatment with castor oil, hot baths, rectal wash-outs, and 1-grain doses of hydrarg. c. creta. The child seemed to improve after the first hot bath, but the heart did not slow down at all. A restless night followed, and when morning came I advised consultation with another practitioner, Dr. Owen Jones, who confirmed the bad prognosis. Dover's powder (1 grain) was given three times a day, and certainly afforded a little more rest that night, but had no effect on the heart, and the following day hypodermic doses of digitalin (1/100 grain) were continued every four hours, with brandy and milk by the mouth. On the evening of Saturday, as the child had not improved and the heart condition showed not the slightest response to digitalin, I further advised a consultation with Dr. Ivor Davies of Cardiff, who saw the child with me that night, but nothing fresh was discovered. Lumbar puncture was performed, and cerebro-spinal fluid, which was under great pressure, was removed to about 3 c.cm. It was clear, and to the naked eye normal. A hypodermic injection of camphor in oil was given and the digitalin was repeated every four hours throughout the night.

The following day, Sunday, there was still no change. The child was put back on to the breast and took the feed quite normally without distress throughout the day. The liver had become enlarged and pulsated, and the heart was a trifle outside the nipple line; the rate remained the same. Digitalin was repeated throughout the Monday, but had no effect on the heart. Doses of atropine sulphate (1/200 grain) were administered without effect. Cheyne-Stokes breathing set in on Monday night, and I concluded that the child could not live until the morning, although its appearance remained good.

On Tuesday the temperature rose to 102° and râles developed at both bases. The heart beat as rapidly as ever. Atropine was again repeated, with no success. A tight abdominal binder in place of a knitted one was applied that night, but it gave rise to such distress in so short a time that it was at once removed. On Wednesday the cough became much more distressing and the symptoms more alarming. A steam tent was fixed up, all stimulants were withdrawn as useless, and the breast feeds with meat extracts only were continued. On Thursday morning, the eighth day of the attack, the heart still continued in its delirium, after a rather more peaceful night, but the bronchitis seemed improved and the child seemed less distressed. About midday the nurse noticed a change in the child. Its pulse was once more to be felt at the wrist; it passed a large quantity of urine, and in every way seemed better. On examining the heart it was found to have regained its normal rate. The liver was once more its normal size, and the breathing was more natural.

In November, 1924, the child had another attack, which lasted only twenty-four hours. The heart had been carefully examined during the interval and found to be perfectly normal. An attempt was made to take an electro-cardiographic tracing, but the age of the patient made it most difficult. In spite of this a normal tracing was produced.

*Note by* IVOR J. DAVIES, M.D., M.R.C.P.

The infant was seen in consultation two days after the onset of the illness, and, although semi-conscious, was but little distressed by the tachycardia, being most comfortable when nursed in an upright position. The colour was good, and respiration, though normal, the pulse could not be felt at the wrist, but was feebly present in the brachial arteries. The temperature was normal. The sounds were best heard in the fifth space just within the nipple line, and were clearly audible for a short distance outside this position, and tic-tac in character. There was no bruit. The rate was very rapid and could not be estimated with any degree of accuracy. The lungs showed a little congestion of the bases. The liver was palpable a fingerbreadth below the costal margin. There was no muscular spasm. The abdominal and tendon reflexes were normal. The lumbar puncture was performed without discomfort and with results as described.

A diagnosis of simple paroxysmal tachycardia was jointly made, because of the abrupt onset following some gastro-intestinal disturbance, the marked tachycardia, which was apparently unaffected by posture or the exertion of crying or by digitalis, and the absence of evidence of any underlying infection. This opinion was subsequently confirmed by a sudden termination with the passage of a considerable amount of pale urine. A guarded prognosis was given because of the signs of early heart failure, but on the whole our view inclined to recovery.

A firm abdominal binder caused discomfort and was discontinued. It was decided to rely mainly upon the small doses of opium and frequent small feeds, which were very well taken.

The occurrence, a few months later, of a second attack, with similar features but of brief duration, makes the diagnosis of paroxysmal tachycardia practically certain. The child appeared to be perfectly healthy and lively a little later when brought up for electro-cardiographic examination. After much difficulty the mother succeeded in keeping the child quiet for a few minutes, and a tracing was successfully taken. The record was normal in all respects.

## Memoranda:

### MEDICAL, SURGICAL, OBSTETRICAL.

#### A CASE OF AVULSION OF THE PARTURIENT UTERUS.

In the spring of 1915 I was asked by my friend, the late Dr. X, to give an anaesthetic for him in a midwifery case he expected to attend in a few weeks. I declined to do this, but offered to help him in any other way if he required more assistance. I heard nothing for some little time, until one morning he asked me to see the woman, who had been confined during the night, as soon as possible. He told me that Dr. Y (now dead) had helped him, and I stipulated that Dr. Y should be told of my visit and asked to be present. The invitation was given, but not acted upon.

Upon arriving at the house Dr. X told me that Dr. Y had delivered the woman with forceps, and that he, Dr. X, had given chloroform. The woman had had several children and had always required help in this form. After the child was born Dr. Y removed the placenta (query, by traction on the cord), and, making a further vaginal examination, said, "There is a large fibroid hanging in the vagina; I think I can pull it out." Then, what Dr. X described as "a frightful struggle" took place, and eventually Dr. Y pulled a large mass out of the vagina, looked at it, and, without saying a word, took it downstairs with him. The patient bled furiously for a short time and became very ill. As soon as she rallied Dr. X went downstairs and found Dr. Y sitting gazing at the supposed fibroid, which was on a dish in front of him. Dr. X asked, "Is that the uterus?" and Dr. Y admitted that it was. They discussed what was to be done, and they decided to burn it, and the uterus was put on the fire and covered up with coal.

After upbraiding Dr. X for allowing the destruction of the specimen, I went upstairs to see his patient. She was very ill. Palpation of the abdomen proved the absence of the uterus, and this was confirmed when I made a vaginal examination to make sure that no intestine was prolapsed into the vagina. There being no complication of that sort, I decided that she had the best chance of recovery by not attempting her removal at that time. The vulva was cleaned up, an antiseptic pad applied, and all douching forbidden. Dr. X asked me to see her daily for a few days, and on the third day we were told that the woman was passing faeces from the vagina. We confirmed this, but made no alteration in the treatment, which consisted only of quiet, feeding, and external cleanliness.

After ten days or so I had her removed to the Southport Infirmary, where she could be better attended to. Some ten days later I had her taken to the theatre, and under a general anaesthetic, and with the assistance of Dr. W. A. Mackay, made a thorough examination. The uterus had gone. The opening into the abdominal cavity had healed up, the tear into the rectum was found high up in the vagina and was large enough to allow all faecal matter to pass through it.

As I had no permission to do any operation the woman was put back to bed and next day I offered to repair the recto-vaginal fistula after doing a preliminary colostomy. The woman declined to submit to this, and after she had regained her strength she was sent home. Dr. X some three or four years later told me that she had been sent to one of the Liverpool institutions for some operation, from the performance of which she did not recover.

Southport.

FRANCIS J. BILDON, M.B., C.M.

#### CONCURRENT HERPES ZOSTER AND VARICELLA.

On January 26th I was called to a man aged 73. I found him suffering from very intense herpes zoster of the right side, running across the right scapula, under the right axilla, and slightly upward on to the right thorax. He was also suffering from well marked generalized and typical varicella, including papules on the scalp. He was not ill. Dr. W. S. H. Briand of this town kindly saw him with me on January 27th and confirmed the double diagnosis. Both eruptions were typical. The herpes zoster came out, on

January 23rd and was painful; the first crop of generalized eruption came on January 25th; it itched, and the patient states that the feeling is quite different.

Within the last three years I have had two distinct cases in which an adult has had herpes zoster and a child contact has developed varicella just over two weeks later—in one case a man and his little niece, in the other a mother and her son and his little friend who was staying in the house at the time of the eruption of the herpes zoster and left a few days after; both children had the eruption at the same time. To my mind these three coincidences establish the relation of the diseases. The age of the patient whose case is described above is also of interest.

Herne Bay.

R. C. T. EVANS, M.B., B.S.

## SEVERE DERMATITIS PRODUCED BY THIAZOLES.

DEHYDROTHIOTOLUIDINE AND CERTAIN MERCAPTAN DERIVATIVES.

In connexion with investigations of the chemistry of the benzothiazoles which are being carried out in this laboratory, it has frequently been necessary to work with quantities of the well known dye intermediate, 4' amino 1 phenyl 5 methyl benzothiazole, or, as it is more commonly termed, dehydrothiotoluidine, and this base and certain related compounds have been found to have a peculiar action on the skin of the face and hands.

Hot solutions of dehydrothiotoluidine in contact with the skin produce an unpleasant form of dermatitis which is worst between the fingers of the experimenter; the irritation is intense during the first few days. The skin rises in practically colourless semi-blisters, which, on being broken, liberate an almost colourless infectious liquid which spreads the trouble.

Observations of this nature have already been made by other workers in the field of thiazole chemistry; thus A. von Hofmann (Berichte 1887, xx, 2251), at the end of one of his papers on amidophenylmercaptan, states that the vapours of this compound have a most detrimental effect on the skin, producing intense irritation and swelling, the affection spreading to all parts of the body which come into contact with the part attacked. I have observed a similar effect with the higher homologue of this compound obtained in the alkali fusion of dehydrothiotoluidine—that is, ortho-amino-parathioresol—which has a similar physiological action in contact with the skin. Baumann (Berichte 1887, xx, 2251), in connexion with his researches on mercapturic acid, states that effects similar to these were so severe that he was obliged to abandon his investigations on a number of occasions.

In my case the blisters, etc., on the first occasion lasted for several days. Bathing the hands with very hot water has the effect of removing the irritation to a certain extent; bathing with a 2 per cent. solution of phenol in water was also found to have a beneficial effect.

## CHLORACETANILIDES.

In connexion with researches on the synthesis of thiazoles it became necessary to investigate the series of changes:

Chloracetanilide → Thiocyanacetanilide →  
Labile ketothiazole → Stable ketothiazole

and hence necessary to work up quantities of the anilido derivatives of monochloroacetic acid which have been found to possess most unpleasant properties.

The arylamino derivatives of chloroacetic acid are highly poisonous substances; they attack the skin in a most disagreeable manner, producing symptoms similar to those of "poison ivy," causing violent irritation.

Chloroacetylparabromanilide is a most violent poison; so unpleasant are its physiological properties that Johnson and Bristol (*Journ. Amer. Chem. Soc.*, 1903, xxv, 484) were compelled to abandon their investigation on the thiohydantoins. This anilide apparently attacks the connective tissue beneath the skin, causing a superficial oedema and albuminuria, the effect lasting over a month. In my case, however, the customary tests for albumin in the urine gave negative results.

R. F. HUNTER, B.Sc., A.R.C.S., F.C.S.

## Reports of Societies.

### FIBROSITIS.

A DISCUSSION on the nature, prevention, and treatment of fibrositis took place at the Royal Society of Medicine on March 4th and 5th. The Sections of Balneology and Climatolgy, Epidemiology and State Medicine, Medicine, and Therapeutics and Pharmacology united for the purpose.

Dr. W. ENGECOMBE of Harrogate, president of the first of these sections, who took the chair, outlined the scope of the proposed discussion. He said that it must be limited to the non-articular forms of so-called rheumatic disorders; to include arthritis, with which anatomically and etiologically fibrositis was bound up, would make the subject too wide. He quoted the report of the Ministry of Health on the incidence of rheumatic diseases, issued early in 1924, to the effect that one-sixth of the industrial invalidity of the country was due to diseases classed as rheumatic; these diseases each year cost the approved societies nearly £2,000,000 in sick benefit, and involved a loss to the nation of three million weeks of work—this among the insured population alone. The interest of the discussion would chiefly centre around pathogenesis. Until recent years the condition was looked upon as of metabolic origin, but lately the importance of infection in the causation of fibrositis, as of arthritis, had been fully realized, and numerous observers had established the overwhelming part which infection played as an etiological factor. To such an extent indeed had infection been stressed that it might be the pendulum had swung a little too far in this direction. An important point for discussion was whether there were forms of fibrositis of purely metabolic origin and wholly independent of infection. It seemed clear that no one organism was responsible for the pains of fibrositis. Granted that infection by micro-organisms was the dominating factor, the soil for the infection had to be considered very carefully also. Many people harboured foci of infection without suffering from rheumatic manifestations until something occurred to break down their resistance. In some cases no source of infection could be found, and these might recover by treatment wholly directed to putting right the metabolic derangement, but it was extremely difficult to prove that there were cases of purely metabolic origin. The disturbances of metabolism with which fibrositis was most commonly associated were the gouty state, hyperglycaemia, and the results of dietetic errors. The frequent association of fibrositis and neuritis with hyperglycaemia lent support to the view that chemical changes alone were competent to give rise to the condition. If the metabolic origin were denied and the bacterial origin were regarded as universal, treatment on any other than antibacterial lines must be of little use. Treatment might be discussed from the aspects of prevention and of cure. Preventive treatment should embrace the better housing and occupational conditions of industrial workers, the avoidance of damp and chill, better ventilation, the provision of baths and drying-rooms at works, and so on, together with attention to the common sources of septic infection, such as the tonsils and teeth. General curative treatment included first of all the detection and removal of any source of septic infection, but it must also be directed to the underlying metabolic derangement. The local treatments were varied and well known. In his experience the results of vaccine treatment, though striking in a few cases, were disappointing in the majority, especially in the chronic forms, if this treatment was used alone without other measures. Spa treatment offered advantages in the management of these cases, and the Ministry of Health might seriously consider whether spa treatment could not be made available to large numbers of the industrial population whose working life was seriously interrupted by this invalidity. If a series of cases of sciatica or lumbago were sent for institutional treatment to one of the spas and were compared with controls in the shape of similar cases receiving the ordinary

domiciliary treatment, he believed it would be evident that spa treatment could effect a great economic saving.

Dr. J. A. GLOVER (Ministry of Health) gave a summary of the investigation conducted by the Ministry in 1922, when forty-nine practitioners undertook to act as observers with regard to the incidence of rheumatic disease among 92,000 insured persons. It was proved that fibrositis was extremely common. Out of 58,000 males of all ages from 16 upwards, there were 1,100 cases of fibrositis. Half of these were cases of lumbago, one-third were cases of muscular rheumatism other than lumbago, and nearly one-sixth were cases of sciatica or brachial neuritis. The figures for females were less dependable because so many women went out of insurance on marriage that it was difficult to get a fair sample. In muscular rheumatism, excluding lumbago, the female attack rate was considerably higher than the male in every age group. In lumbago, however, the male attack rate was far higher than the female at all ages, and in the youngest group (16 to 24) more than double. In the case of brachial neuritis nearly three women were attacked to every two men. The comparative absence of lumbago among women might be partly ascribed to the smaller occupational stress experienced by women on the lumbar muscles, and the same might explain the higher sciatica incidence in the male; but it was difficult to see why women should suffer more from brachial neuritis, unless it was accounted for by the greater openness of their dress. He gave some statistics obtained in Leipzig fifteen years ago, where the attack rate in males from 16 to 24 was nearly four times as great as in this country; this was not due to the inclusion in the Leipzig figures of attacks of lighter character, for the period of absence from work was longer in Leipzig all the way through. With regard to occupation, it was generally found that metal workers were particularly affected with lumbago, due, no doubt, not only to the heavy work, but to the liability to chill. Lead also was an occupational factor of importance; a considerable proportion—13 per cent. according to Goadby—of cases of lead poisoning showed rheumatic manifestations.

Sir WILLIAM WILCOX recalled that, four years ago, in a discussion at the society, when he mentioned the word "fibrositis" a smile went round the room, evidently due to the belief that this was a fictitious disease. Recent work had shown by actual microscopical and histological examination the existence of chronic inflammation in the tissues. The lumps and thickenings felt by a skilled masseur in the parts of the body affected by fibrositis had an actual existence. In France a good deal of attention had been paid to radiographic examination, and he exhibited some x-ray photographs taken by Dr. Gaston, of the St. Louis Hospital, Paris, which showed shadows in the vertebrae caused by a deposit in a severe case of fibrositis. It was well known that fibrositis resulted from a number of specific infections, such as gonorrhoea, bacillary dysentery, Malta fever, pneumococcal infections, the enteric group of diseases, scarlet fever, tuberculosis, and syphilis. The President had asked whether fibrositis was always due to bacterial infection. The speaker was bound to agree that metabolic conditions such as gout and toxic conditions such as lead poisoning were commonly associated with fibrositis, but he was inclined to take the view that in these conditions there was a superadded infection as well. In most cases of gout there was evidence of intestinal toxæmia. Everyone would agree as to the important part played by focal sepsis as a cause of fibrositis. In the appreciation of focal sepsis British medicine was far in advance of Continental. Often very careful search was needed to find the focus of infection. Sometimes a case of advanced arthritis or fibrositis was met with in which there was no obvious focus of infection, though he believed such cases to be comparatively rare. During the last four years he had had at least thirty cases of fibrositis where an x-ray examination had disclosed an opaque antrum, although there were no symptoms of any naso-pharyngeal disease. The antrum proved to be filled with pus, and the treatment of this condition was usually followed by rapid and progressive improvement. It was important to realize that when a focal infection had acted as such for a certain time it

would not be long before secondary infections followed, the colon might be invaded, or the tonsils or teeth, and one had to remember that there was lymphoid tissue not only in the tonsils but scattered through the pharynx and other parts of the body. Thus a secondary infection might go forward without any gross or obvious focus. Fibrositis was a kind of gauge which measured the balance between the infection and the immunity of the patient. Normally a certain amount of absorption of toxins of bacterial origin must be constantly taking place. In health the body fluids were able to neutralize these toxic substances; in fibrositis the toxins were in excess of the protective substances, and it was this excess which determined the degree of the fibrositis. He went on to call attention to two factors not generally realized at the present day. The first was the condition known as sensitization. In many of the cases in which the vaccines failed the reason was that the patient had become sensitized to the infection. Another important factor was the condition known as symbiosis. Here one found a disease caused by the infection of one organism lowering the resistance of the body to the organism causing fibrositis. This was seen excellently in people who had become infected by malaria; these were very susceptible to fibrositis, but if cured of malaria they could put up a fight against the *Streptococcus viridans*, and the cure of the fibrositis followed. The speaker regarded fibrositis, not as a disease, but as a symptom of toxæmia, and evidence of streptococcal toxæmia could be found in most cases on searching. With regard to prevention, what was needed was periodical inspection by those skilled in the search for focal sepsis. If only what was done to some extent in schools could be applied to a larger number of individuals an early development of focal sepsis would be recognized and dealt with, and the health of the community would be enormously improved. No field of public health was more promising. Most of the common disabling diseases which he saw in persons over 40 were due to focal infections. With regard to the treatment, he strongly deprecated the use of vaccines in fibrositis unless the focus of infection had been completely removed. Given this preliminary condition, vaccines were a help in selected cases. Intestinal disinfectants were useful, but not very great reliance could be placed on drugs. Various forms of electrical treatment, poulticing, and the application of heat were of service, and skilled massage in the chronic stage was most valuable. Anaphylactic treatment had been used in fibrositis, but he had not seen any good result from it, and he did not think the method sound scientifically.

Dr. P. HAMILL agreed that a very large proportion of cases were definitely infective in origin. The virulence of the infecting agent was low, but its chronicity was great. The number of organisms that might produce fibrositis was legion. The part played by syphilis was obscure. Some cases of apparently typical fibrositis gave a positive Wassermann reaction, and did remarkably well under anti-syphilitic treatment, but he thought it likely that the resistance of the patient to another infection. Many cases of fibrositis and sciatica were undoubtedly due to colitis and dysentery. The first canon of treatment was to find and eradicate the cause. A careful history was often of great assistance. Cases were met with which gave a history of attacks of lumbago or stiff neck, and in association with throat, or slight aching of the gums. Such points in history gave a clear hint as to the source of infection. In the majority of cases, however, no such clues were forthcoming. He urged the importance of x-ray examination in all cases in which the teeth were suspected to be the cause of the trouble. Tonsils also were a frequent and unsuspected cause. The abdominal viscera were a great potential source of infection, and the appendix was of importance; often cases which improved up to a certain point, and then went no further, cleared up after the appendix was removed. In his experience chronic pelvic inflammation in women was not associated with fibrositis quite as commonly as one might expect. Having removed the primary source if possible, the next step was to combat

the residual infection. Intestinal intoxication could be diminished by securing efficient evacuation of the bowels. The resistance and immunity of the patient must be raised by every means available, such as an ample and varied dietary, fresh air and sunlight, and attention to housing and sanitation. In this connexion the various health resorts could be of considerable value. He believed there was a definite place for spa treatment in these diseases. With regard to non-specific measures, protein shock would commonly produce a remarkable benefit, but not a lasting one, in his experience. It was more likely to be of value in the early cases before the patient's immunity had reached too low a level. With regard to specific measures, the results obtainable by vaccine therapy, if judiciously carried out, were encouraging. In acute cases, especially when arthritis was coexistent, complete rest with splinting was desired. Where there were contractures, splints and extension should be employed, but splinting must be combined with massage and movements in chronic cases. Heat in various forms acted usefully in increasing the blood supply and releasing the spastic muscles; diathermy was the best method. The chief trouble in long-standing cases was the mental supineness of the patients, who wanted everything done for them, and made little effort to assist themselves; they needed cheerful surroundings and constant encouragement.

Dr. R. ACKERLEY (Llandrindod Wells) said that it was not any specific organism which caused fibrositis, but it might be any toxin which invaded the body. He referred to a discussion which took place in the society as long ago as 1913, when he declared that his clinical experience led him to the belief that any toxin, if retained in the body, was sufficient to cause first fibrosis, and then fibrositis, the first being a gradual and painless process. Owing to the habits of civilized life, toxins, whether metabolic or other, tended to accumulate in the body, partly as a result of repeated infections, but far more as a result of defective elimination. The body tended to let these organisms accumulate in the tissues of lowest vitality, and it was due to this gradual accumulation that these fibrous thickenings and enlargements made their appearance. Everyone who had treated discharged soldiers was aware that fibrositis followed every infective disease—dysentery, malaria, Malta fever, and so forth. Very often the toxins were not in a condition to be eliminated through the ordinary eliminative organs. They were imperfectly oxidized. Imperfect oxidation was one of the most characteristic features of modern life. The conditions under which most people lived, spending hours in stagnant, not necessarily impure, air, led to imperfect oxidation, and this it was which caused the increase of these pains in damp weather. Two years' experience in Egypt showed him that there, with overcast skies on some days in winter and the great humidity of the Nile valley, the people complained of such pains very much more than during the winter in England. It was interesting to see how the fibrous tissues tended to swell up under such conditions. This also he put down very largely to defective oxidation. Any treatment must begin with the complete eradication of any focal sepsis, and then must be directed to restoring function and tone to the various tissues and eliminate the toxins already there.

This concluded the first day's discussion.

At the resumed discussion, with Dr. ENGELSMAN again in the chair,

Dr. W. J. MIDELTON (Bournemouth) deprecated the number of labels existing to-day, which were puzzling and misleading; almost the only label wanted was toxæmia, chronic or acute. He had no faith in all that was said about staphylococci and streptococci. In all cases, he believed, the underlying condition was some result of an earlier infection—measles, scarlet fever, typhoid, and so forth—and the staphylococci and streptococci were purely secondary. One of his theories was "once infected, always infected." He gave particulars and showed photographs of treatment introduced by Dr. P. W. Latham for the fibrous lesions, which in his hands had given good results.

Dr. H. A. ELLIS said that one would imagine from the tone of the discussion that there was nothing in fibrositis but a septic condition; that was true to a certain extent

only. Many of the difficulties of the situation would be met by considering the matter from a biochemical aspect as against a purely bacterial aspect. The different incidence between men and women was difficult to understand on a purely bacterial basis. The conclusion he himself had reached was that this was a biochemical condition activated by many causes, of which bacterial invasion was undoubtedly one, but only one. A man could drink port and bring on lumbago, which came under the head of fibrositis; but did anybody think that that was bacterial? Fibrositis fell into two main groups—one in which the activating cause was assimilation errors, and the other in which it was elimination errors. Assimilation errors were those in which there was insufficient food. Cases due to such errors must be treated with acid—phosphoric acid was the best—and the other cases, those of metabolic excess due to elimination errors, had to be treated with alkaline potash—trihasic potassium phosphato he had found most useful.

Mr. J. E. R. McDONAGH said that fibrositis was an inflammation of the supporting tissues of the body, which included the fibrous tissue. It was seldom that the fibrous tissue alone was picked out; hence fibrositis was more often one of the manifestations of the general involvement of the supporting tissue than a clinical entity. Chronic fibrositis might not give rise to clinical symptoms until all the signs of what was understood to be inflammation had vanished, and in those cases one was dealing more with the result of what had been than with an actively progressing condition. Speaking of fibrositis in women of child-bearing age, he said that it was in this class of case that focal infection would appear to play its chief part; it was most apt to lie either in the teeth, the tonsils, or the bowels. In the majority of cases there was a streptococcal invasion. Although theoretically any micro-organism might cause fibrositis, he doubted whether many cases would be seen if the streptococcus and the gonococcus could be banished. A very large number of women had fibrositis at the climacteric, and this deserved to be regarded as a distinct condition, because it was likely to be due to the chemio-physical changes which the blood underwent at this period. The prognosis was good, and in his experience the condition did not progress to acid-arthritis. Gout was not a disease *sui generis*, but merely a clinical manifestation of what might be termed shock taking place in one of the supporting tissues. Chronic fibrositis in elderly people practically never occurred alone; it was merely one of the local manifestations of general fibrosis.

Dr. M. B. RAY said that the general tendency appeared to be to confine the use of the term "fibrositis" to non-articular situations. The huge fibrous envelope which sent prolongations everywhere must of necessity be deeply concerned with all the biological interchanges of fluids which were continually taking place as a result of bodily activity. In ordinary conditions of health and absence of fatigue there was perfect harmony in the interaction between nervous impulse and muscular response. Any obstacle might be due to inefficient removal of the products of muscular activity or changes in the plasma which in some way inhibited the processes of interchange. He did not think that sufficient attention had been paid to the lymph circulation in this condition.

Dr. OLIVER HEATH, as a pathologist, entered a mild protest against the use of the word "toxin" in this connexion. By "toxin" was understood something like that which was produced by the diphtheria bacillus, but with the common organisms which produced sepsis nothing of that kind had been discovered, and he objected to the widening of the term. He gave a description of his own experiences as a sufferer from lumbago. He had tried various simple treatments, including walking, which was sometimes recommended, but which really did not exercise the lumbar muscles at all, and resting, which was equally unavailing for the cure of lumbago. Finally, however, the lumbago disappeared quite rapidly as the result of careful and skilled massage, first applied with a very light touch indeed, in the direction of the lymph flow, until, perhaps within fifteen minutes, it was possible even to knead the part with the knuckles. Later, in an experimental fever produced on himself by the injection of typhoid vaccine into

a vein, intenso lumbago was one of the manifestations, and after a time he succeeded in making it disappear by undertaking steady exercise for an hour or two, involving frequent bending forward of the body as though to pick up an object from the ground, and then straightening. This exercise of the lumbar muscles proved very efficacious.

Dr. C. E. SUNDELL pointed out the subnormal temperature of persons suffering from this condition. Persons with fibrositis also had a skin naturally inactive. When sweating was induced the reaction of the sweat, as tested by litmus paper, was strongly acid, in striking contrast to the neutral or faintly alkaline reaction of the sweat of the normal individual. The acidity of the sweat depended upon the presence of large quantities of lactic acid.

Dr. HUBERT HIGGINS gave some description of French investigations on this subject, and also recalled a case of his own in which the hands were very seriously affected, becoming absolutely useless and extremely painful, the real cause being a block obstructing the lymph circulation. Radiation of various kinds proved unavailing, but the condition yielded to a system of massage, alternate pressure and relaxation, and in four or five days the use of the hands began to return.

Dr. PARKES WEBER said that he agreed in general with the views expressed by Sir William Willcox and Dr. Ellis, but with regard to the French radiograph, which the former had shown—indicating shadows in the vertebrae, which it was urged were significant of fibrositis—he found difficulty in accepting the case as one of that condition; there were other forms of calcification besides fibrositis, and he rather questioned the diagnosis.

Dr. EDGEcombe, from the chair, in summing up the discussion, referred to the cleavage of opinion as to whether any cases of fibrositis were of purely metabolic origin. This must be left an open question. Everybody would agree, however, that in infective cases the commonest organisms were the streptococci, notably of the *viridans* group. The value of vaccine treatment, alone or combined, and the limitations of its use, had been clearly set out. He thought also that it was common ground that in the later and more chronic stages of fibrositis spa treatment had a definite place.

## THE FUNDUS OCULI IN GENERAL MEDICINE.

At a meeting of the Medical Society of London on March 9th, with the President (Dr. E. M. CALLENDER) in the chair, a discussion took place on the fundus oculi in general medicine.

Mr. ERNEST CLARKE said that the advantages of ophthalmoscopy in medicine had been greatly furthered by the advent of the luminous ophthalmoscope, which brought the practice within the range of every medical man. With this instrument a dark room was not indispensable, and the patient could be examined in any position. But it was one thing to see the fundus, and another to interpret what was seen. It was only by constant practice that the observer acquired the capacity for recognizing the abnormal. In this connexion a sequence of picture records was of great value, but until lately such records were not easy to obtain, for an artist had to be specially trained, and, moreover, had to learn to draw to some extent from memory, so as not to worry the patient too much or light up the eyes for too long. In this connexion it was a great advantage that a studio staffed with trained artists should have been opened by Theodoro Hamblin, Ltd., where a patient could have a sitting at any time. It was next to impossible to describe small changes in the fundus, but if a series of pictures were taken by the same artist, or by artists trained in the same technique, it was extremely useful. Mr. Clarke proceeded to show a large number of fundus drawings of exceptional and interesting cases. These included one which illustrated the dire results, as shown in the fundus, of acute veronal poisoning. After taking an overdose of veronal, which was followed by unconsciousness for some days, the fundus in both eyes was found to exhibit a considerable amount of papillitis and haemorrhage. It was suspected that there was a cerebral tumour, and that the veronal poisoning was merely a side issue, but after careful treatment the eye condition completely cleared up within a

month or two. Another case was one of diabetic retinitis, which cleared up under insulin. He urged in conclusion the importance of forming a permanent library of fundus records, the value of which might be disseminated by means of lantern slides.

Dr. F. PARKES WEBER referred to the ophthalmoscopic appearance in death, a subject on which he had already written a note in the BRITISH MEDICAL JOURNAL, (1924, i, p. 497), following upon an article in the JOURNAL by Ernest Bulmer. While he was house-physician he made a practice of examining the fundus immediately after death. He found the columns of blood in the retinal vessels interrupted by small spaces which could be moved backwards and forwards by pressure on the chest as in artificial respiration. In one case in which a spontaneous respiration took place he had found this ophthalmoscopic phenomenon of segmentation already present. In certain cases, however, after death he failed to find any segmentation, although the cornea had not yet become sufficiently clouded to prevent him from seeing the fundus. The absence of such segmentation, therefore, must not be taken as a sign that death had not occurred.

Dr. JAMES COLLIER affirmed the need for ophthalmoscopic investigation in every case of illness whatsoever. It was one of those superficial examinations which could be carried out in a moment, like feeling the pulse. The examination was easy, the technical details could be learned in a few days, the instruments were good, every fundus was interesting, and the beginner could practise on normal subjects. The fault in the teaching of students was that not enough examination of normal subjects was made. In his own sixteen years' practice as physician to the Royal Eye Hospital the frequency with which general medical diseases had been diagnosed for the first time from the examination of the eyes had been remarkable. In diabetes, renal disease, syphilis, tuberculosis, septic conditions of the accessory cavities, the first symptom might be ocular. Even more important than these positive findings were the negative findings—that the fundus oculi was normal in cases in which recurrent headaches, transient blindness, liability to fits, and other manifestations had suggested the possibility of intracranial lesions.

Sir WILLIAM WILLCOX spoke of eye lesions due to toxæmia. Until comparatively recently one was taught that changes in the fundus oculi were due to diabetes, Bright's disease, or high blood pressure; but one knew from experience that it was extremely common nowadays to find haemorrhages and marked changes in the fundus with no increase in blood pressure, no diabetes, and a normal renal function. It was most important to watch every channel of infection—the teeth, the antra, and the various sinuses. If there was a focus of infection and this was removed it was extraordinary how quickly the eye condition cleared up. Certain drugs, of which atoxyl was perhaps the best example, had an affinity for the retinal tissues, and one common drug which affected the retina in certain people was quinine. He recalled the case of an officer in India during the war who, developing a slight fever, was given 10 gr. of quinine by the R.A.M.C. officer, and immediately became deaf and delirious, whereupon the dose was increased to 15 gr., and he became blind. When he (the speaker) saw the case, recognizing the idiosyncrasy of some people to quinine, he stopped this drug, gave the patient a dose of aspirin, and sent him to hospital, where he recovered his sight completely.

Dr. RAYNER BATTEN emphasized the need for collective drawings by different observers, and showed a very beautiful series of cases illustrating changes taking place at the yellow spot. The President, speaking as a general practitioner, remarked upon the extreme usefulness of an atlas of such records as had been shown that evening.

## DIFFERENTIAL DIAGNOSIS OF SOME EXANTHEMATA.

At a meeting of the Medical Officers of Schools Association on March 6th, Dr. L. R. LEMPRIERE presiding, a discussion took place on the differential diagnosis of scarlet fever, measles, rubella, and allied rashes.

Dr. E. W. GOODALL, in opening, said that one mistake frequently made, especially by younger men, was to suppose

that the diagnosis in these cases could be made on one symptom. The diagnosis had nearly always to be made on a combination of symptoms. Except Koplik's spots in measles, there was no one symptom which could be said to be distinctive. Of all these diseases the most difficult to diagnose was scarlet fever. No single symptom was characteristic of scarlet fever—not the rash, nor the faucial lesions, nor the "strawberry tongue" (for an instance of "strawberry tongue" he would go first to the measles ward), nor the peeling. The diagnosis of scarlet fever could only be made on a combination and sequence of signs and symptoms. With regard to measles, he did not think that the anomalous cases were quite so common as in scarlet fever. The rash, however, might be extremely slight, hardly noticeable at all, and there were some cases in which Koplik's spots were not present or were so transient as to be missed. He believed also that rubella might exist without any rash. With regard to fourth disease, or "para-scarlet," he could not say that he had ever seen this disease in epidemic form. It was said to be a scarlatiniform variety of rubella, but of this he had always been rather sceptical. Speaking of rashes which might lead to a mistaken diagnosis, he said that the rash in rubella in the second stage was very like that of scarlet fever, and so was the rash in the later stage of measles. The rashes of chicken-pox and small-pox, and even occasionally of typhus, might be extremely like scarlet fever. Eczema rashes also might be mistaken for scarlet fever or even for measles. The rash of scarlet fever might also be simulated by drug rashes, especially those due to quinine, and another confusing condition was recurrent scarlatiniform erythema. Again, influenza might cause a similar rash to scarlet fever. The most common drug to produce a rash like measles was antitoxie serum. Septic rashes were never scarlatiniform, but frequently morbilliform. He had seen encephalitis twice diagnosed as measles. But all these cases had other symptoms quite incompatible with measles, and it was usually only a matter calling for a little investigation to clear up the diagnosis.

Dr. G. E. FRIEND (Christ's Hospital) gave particulars of a number of epidemics of measles, scarlet fever, rubella, and fourth disease. In fourteen out of twenty-eight epidemics the number of cases in an epidemic was fewer than ten. He described a considerable epidemic in 1916 which began as rubella and went on as scarlet fever. It comprised 204 cases in all, including 11 cases of definite scarlet fever with 1 death, 45 cases of "para-scarlet," or fourth disease, with 1 death, and 148 cases of rubella with no death. He pointed out certain differences in the description of the rash in rubella, as given in the works of Osler, of Allbutt and Rolleston, and in school textbooks, and for his own part declared his belief that there was only one type of rash for any one acute infection. The rose-red papule in rubella was always present at first, though later it tended to become a morbilliform rash. The fact that three types of rash were so commonly described in rubella was good evidence that there was considerable diversity of opinion with regard to that condition. This led him to speak of "para-scarlet," of which condition he had found two varieties, and in both he believed the causal organism to be a haemolytic streptococcus, which had been found in 96 per cent. of the cases swabbed. In 75 per cent. of cases of measles he had found Koplik's spots two days before the appearance of the rash on the body; in 20 per cent. of cases he had found this sign within a shorter interval, though still definitely appearing before the rash; and in the remaining cases the appearance was coincident with the rash. He emphasized the need for basing the diagnosis on a combination of symptoms before a definite opinion was ventured, especially on a first case of scarlet fever.

In a short discussion Dr. GRAHAM FORBES asked whether there could be a definite recurrence of measles, apart from mere relapse, to which Dr. GOODALL replied that he had seen two cases of measles, but only two, with second attacks developing within a few months. Dr. ELWIN NASH said that the rash which was the medical officer's bugbear was that of modern scarlet fever, which was simulated by so many rashes of other kinds. Dr. C. E. SHELLEY attributed the appearance of "para" forms of disease to the different degrees of struggle which the pathogenic organism under-

went in the effort at survival; and to this Dr. GOODALL replied that he believed organisms had two different functions—one, infectivity pure and simple, and the other, what might be called virulence, exerting itself chiefly in damage to the host, and that one or other of these might in different cases be in the ascendant.

## Rubellus.

### LEPROSY.

It is a remarkable thing that since the celebrated Norwegian leprologists, Hansen and Looft, published their treatise about 1895, no authoritative and comprehensive work on leprosy has been issued until the recent appearance of the volume with the title *Leprosy*,<sup>1</sup> which we owe to Sir LEONARD ROGERS and Dr. ERNEST MUIR. This is the more noteworthy when we consider that leprosy takes rank with tuberculosis and syphilis as one of the major ills by which humanity is afflicted. It is true that many papers on leprosy have appeared during the last generation; for a short time there was a journal, *Leprosy*, exclusively devoted to the study of the disease; and about two years ago Dr. Muir wrote a short book mainly dealing with the newer methods of treatment, which we owe principally to the genius of Sir Leonard Rogers; but that is all. These new methods have changed the entire aspect of the leprosy problem, both from the point of view of the victims, to whom they have brought hope for the first time in history, and from the point of view of public health authorities, especially in the tropics, who can now envisage the prospect of controlling the spread of the disease, of reducing the numbers of the leprosy, of even, if they are given the necessary help and encouragement by their Governments, making leprosy as rare in the tropics and other endemic areas as it is now in our own country. It is, therefore, fitting that Sir Leonard Rogers, to whom we owe this wonderful advance, and Dr. Muir, at whose hands the new methods have been put to the proof, should unite in producing the present work, which deals with leprosy in detail from every aspect, and which will, no doubt, long remain the authoritative handbook of the subject.

It is now, of course, thoroughly established that leprosy is a contagious disease due to infection with the specific bacillus discovered by Hansen in 1871; but such is the length and uncertainty of the incubation period that for many years the theory that the disease was always contracted by heredity was strongly supported, and this erroneous hypothesis received unfortunately fresh vigour from the report of the Royal College of Physicians in 1865, which concluded that leprosy was "not contagious or communicable to healthy persons by proximity or contact with the diseased." On the strength of this report the Colonial Secretary issued orders to cease enforcing and to repeal all laws affecting the personal liberty of lepers; the result was an immediate but gradual increase of leprosy in all directions affected. We need not here detail the overwhelming case for the contagiousness of leprosy, but it is interesting to note that even now the exact portal of incubation is not absolutely established, though there is a good deal of evidence that in the majority of cases the infection is due to direct inoculation through the skin or nasal membranes—through the skin in hot climates where clothes are scanty, through the nasal mucosa in colder climates where more clothes are worn—although bed bugs may not be entirely guiltless of the charge of acting as carriers. There is a vast difference among lepers as to their potential danger as sources of infection. Those who are in the first stage, when the bacilli are few and the lesions are not yet ulcerated, and those who are in the third stage, in whom the disease has worn itself out and may be regarded as cured, even although the patient has been reduced to a mutilated caricature of humanity, are comparatively innocuous; it is in the second stage, when the bacilli are

<sup>1</sup> *Leprosy*. By Sir Leonard Rogers, C.I.E., F.R.S., etc., and Ernest Muir, M.D., F.R.C.S. Edin. Bristol: J. Wright and Sons, Ltd.; London: Simpkin, Marshall, Hamilton, Kent, and Co., Ltd. 1925. (Demy 8vo, pp. xii + 301; 32 plates, 55 figures. Paper cover, 10s. 6d.; cloth, 12s. 6d. net.)

numerous and are being shed in large numbers from the skin and in the secretions, that they are most infectious.

A considerable section of the book is occupied with an account of the pathology of the disease and a description of the clinical lesions. This section is, of course, very important to those who will have to deal with leprosy clinically, but what will interest most readers much more is the section on treatment. The treatment of leprosy may be divided into two parts. Leprosy, like tuberculosis, is a disease of poverty and squalor, and lepers, when removed from their unhealthy environment, improve in health without any further aid, just as tuberculous patients improve in a sanatorium. The first necessity, therefore, in the treatment of lepers is the improvement of their hygienic conditions and the removal of any exciting cause—for example, the treatment of any intercurrent disease, such as syphilis, malaria, or kala-azar. But, as a rule, more than this is required, and it is in the specific treatment that the important advances have been made. The story is analogous to the story of the treatment of malaria by quinine and the treatment of dysentery by emetine. In those cases the traditional popular remedies—cinchona bark and ipecacuanha—were studied scientifically, their active principles were isolated, and their utility enhanced. In leprosy much the same thing has been done by Sir Leonard Rogers as he did for amoebic dysentery. Starting from the fact that chaulmoogra oil has long been known as the only real remedy for leprosy, he has striven to overcome the great disadvantages and limitations of the crude drug, and to a large extent has succeeded. He has substituted for the administration of this nauseating substance by the mouth the intramuscular and subcutaneous injection of its derivatives. Moreover, he has examined oils derived from plants of allied species and has discovered amongst them bodies which are found to be even more powerfully antileprosy. Chaulmoogra oil is derived from the seeds of a tree, *Taraktogenos kurzii*, but *hydnoearpus* oil, derived from the allied genus *Hydnoearpus*, appears to be better, and has the additional advantage that the parent tree is grown in gardens and accessible places all over Southern India, whereas *Taraktogenos* is found only in out-of-the-way places, and it is not easy to get fresh seeds. As to the details of preparation of the various active bodies and the method of administration, the reader must consult the original work; but it may be said that considerable judgement and experience are required to obtain the best results, and this is no doubt one reason why some observers have not obtained such favourable results as others.

The best prognosis seems to be in cases in which the disease is either in the first or third stage; in the second, when the bacilli are present in great numbers all over the body, the reactionary effects of the drugs, which are important, may be so severe as to cause anxiety. On the other hand, the successful treatment of leprosy is almost always associated with reaction. It must be remembered that leprosy, unlike its sister plague tuberculosis, attacks for the most part non-vital organs, and that therefore a degree of reaction, which in a tuberculous lung would entail dangerous consequences, plays a beneficial part in the treatment of leprosy, though it must not be allowed to exceed certain limits. The success which has attended the use of the newer methods of treatment is well illustrated by the series of photographs of patients before and after treatment. But their success has had, and is now having in greater degree, still more important results. Encouraged by the cures which they have heard of or seen lepers are now beginning to come forward voluntarily for treatment instead of concealing themselves for fear of forcible segregation, or at least of the social ostracism which is associated with the disease. Some are being treated in leper colonies and settlements, but many more as outpatients at the hospitals. The result is that in India and elsewhere their numbers are now beginning to diminish, and at last there is hope that the leper problem may be solved. We recommend this book unreservedly, not only to those who are actively interested in dealing with leprosy, to whom indeed it will be indispensable, but also to all who are concerned with the problems of public health, especially in the tropics.

## THE EXAMINATION OF WATERS.

The treatise by Drs. THRESH and BEALE on *The Examination of Waters and Water Supplies* has reached a third edition<sup>2</sup>; since the second edition was published much new and important knowledge has been gained on the subject of water supplies. Very fortunately that knowledge in its practical applications makes both for extension of safe sources of supply and for economy in the methods of treatment of waters to render them suitable for public use. In the past rivers liable to pollution by populous places have been avoided or regarded with suspicion, notwithstanding the very striking case of London and its dependence mainly on the Thames. Now, however, rivers—not, of course, open ditches receiving heavy discharges from large manufacturing towns—can be resorted to without hesitation if proper measures are taken for the protection of the public. These means include two inexpensive alternative processes of chemical purification—by chlorination and by excess of lime—both of them achieving a large measure of bacterial purification, even, in the case of lime, “almost complete sterilization.” Though the value of chlorination had been discovered before the war—Lincoln adopted the method in 1905, and Reading in 1910—yet it was the army's resort to it during the war, as well as the Metropolitan Water Board's adoption of it in the war period, that aroused general interest in the new system. And now, as the authors of the work under notice point out, Sir Alexander Houston has recently proved the remarkable value of treatment by excess of lime. All this is set forth by the authors of the work under notice, and, following the chapters on purification of water by storage, and by sand filtration, the two outstanding chemical methods are fully described and discussed. A mere list of the titles of the thirty-three chapters which compose the volume would indicate that no problem of any importance has been left out.

The bacteriology of the subject in relation both to the examination of water and to the interpretation of results is dealt with in the later part of the treatise. Here the authors wisely pass by a great mass of investigation and exposition belonging to the early days, remarking that now “the sum total of the information available, bearing upon the interpretation of results, is comparatively small.” At one time “the estimation of the number of organisms present was held to be of the highest importance,” and when that idea was exploded the number of different kinds of organisms came into prominence, “but latterly this view has received less support, and now it is deemed absolutely necessary to examine a water for certain definite bacteria, the number of other organisms present being considered of comparatively trifling importance.” Organisms of the intestinal type are, of course, those on which attention is specially concentrated—(1) the *Bacillus coli*, (2) the *Bacillus enteritidis sporogenes* of Klein (now often called the *Bacillus welchii*), and (3) streptococci. These are dealt with at length, whilst the cholera spirillum and the *Bacillus pyocyaneus* are discussed briefly. The authors have found recently the last named in two samples of water, to which outbreaks of diarrhoea were attributed.

The volume, which is illustrated by an excellent series of plates of the microscopic flora and fauna of waters, will be of the greatest value to all who have serious administrative responsibilities for the provision and control of water supplies; indeed, in this country it is difficult to see how any educated water specialist can avoid finding a place for it on his shelves.

## SEROLOGICAL STUDIES OF HUMAN RED CORPUSCLES.

The subject of isohaemagglutination, which is of particular interest from the point of view of blood transfusion, has been carefully studied by Dr. SIXTEN HESSER in a monograph entitled *Serological Studies of Human Red Corpuscles*.<sup>3</sup> It forms one of the *Acta Medica Scandinavica*,

*ers and Water Supplies*. By John C. Thresh, M.Camb., and John F. Beale, M.A.Cantab., D.P.H.Oxon. Third edition. London: J. and B., pp. xiii + 590; 26 plates, 21 figures.

<sup>3</sup> *Serological Studies of Human Red Corpuscles*. By Sixten Hesser. *Acta Medica Scandinavica*, Supplementum IX. Stockholm: P. A. Norstedt and Söner. 1924. (Med. 8vo, pp. 94.)

which includes articles on internal medicine, published in English, French, or German; according to the decision of the author. In this case the author has selected the English language, with which he has taken comparatively few liberties.

The main conclusions to which Dr. Hesser's researches have led him are that the distribution of the four blood groups among Swedes agrees with the distribution of these groups among other European races, especially among Danes and Norwegians and Scandinavians resident in the United States. The tests were made on patients who showed a negative Wassermann reaction, but he has been able to show that the group distribution is the same in individuals who show a positive reaction to the Wassermann test. He prepared in rabbits immune serums against each of the four groups of human erythrocytes, and found that they were to some extent specific in type, and that by absorption experiments it was possible to obtain specific serums which qualitatively resembled human serums. The absorption experiments have persuaded him to the opinion, suspected by many in this country and America, that the present methods of grouping are not adequate and that in all probability more than four groups exist. A comparison of the properties of serums prepared against human and sheep erythrocytes tended to show that human corpuscles are relatively easily agglutinated and relatively difficult to haemolyse.

Experiments carried out with red blood corpuscles which had been kept for a few days enabled Dr. Hesser to compare the phenomena of isagglutination and isohaemolysis of human corpuscles, and he believes that isohaemolysins as well as isagglutinins are physiological constituents of the serum, and that those haemolysins only should be regarded as pathological which haemolyse either corpuscles belonging to the same individual or to the same group. He finds also that serum from different individuals belonging to the same group varies in agglutinating power, and that corpuscles from different individuals belonging to the same group may vary in the ease with which they are agglutinated. Such are the main conclusions of this critical study.

#### AN X-RAY ATLAS.

IN the preface to their book entitled *An X-Ray Atlas of the Normal and Abnormal Structures of the Body*,<sup>1</sup> Drs. McKENDRICK and WHITTAKER state that in it "an attempt has been made to provide a series of radiograms illustrating the normal and abnormal structures of the body, and also the more common injuries and diseases." In the first part of the book thirty-seven pages are allotted to reproductions of seventy-two radiographs of various joints, and numerous diagrams are used to aid in interpretation. While they are interesting in their way, it is rather difficult to see the utility of reproducing groups of radiographs of the normal joints taken in a fixed position with the x-ray tube at what is termed (but not described) the "normal focus point," and then moving the tube four inches internally, four inches externally, four inches above, and four inches below. Little attempt is made to explain either the reason for this method of illustration or indeed its usefulness from the diagnostic standpoint, although here and there a suggestion is made that in one or other tube displacement a certain bone or portion of a bone appears to advantage. The radiographs which illustrate this portion of the book are, on the whole, satisfactory.

Following this is a series of some three hundred radiographic illustrations of various conditions, under the headings of (1) injuries and diseases of the limbs; (2) the head, neck, thorax, and spine; and (3) the abdomen. In this part, again, the descriptions of the plates are not quite adequate. It is not enough to reproduce a radiograph of a morbid condition and merely attach to it a statement that it is an example of whatever the authors consider the diagnosis to be; this method of exhibiting x-ray appearances seems to us to be of little, if any,

educational value. Other criticisms which suggest themselves are that the general arrangement does not appear to follow any consecutive plan, that too many of the radiographs are hardly up to the standard of modern radiography, and that while many common and rare conditions are illustrated and referred to, the omissions are very numerous; further, there are, as we think, some mistakes in description.

The book is very well got up and is printed on most excellent paper. There is an appendix and an index.

#### DEATH IN THE POT.

*The Science and Art of Living*,<sup>2</sup> by Dr. LEONARD WILLIAMS, is a popular explanation of the functions of the body and an exposition of the practical lessons to be learnt, especially in relation to digestion and dietetics. Epigrams, alliterations, trenchant tirades, and other extravagances scintillate through its pages. The habits of civilized man, especially his habit of eating cooked food and too much of it, are attacked, and we are told that the major malady of modern civilization is chronic constipation. Some people bow to a magpie, others salute the chimney-sweeper, and Thomas Carlyle took off his hat whenever he met a perfectly healthy-looking man. He might walk the streets of London to-day for a week, says Dr. Williams, without being moved to do so, for he would meet with nothing but muddy complexions, oily skins, and malodorous emanations, proclaiming the hidden cesspool to those who know. In other words, we are all suffering from the major malady. It is, however, the cooking pot that is to blame. Like the sons of the prophets Dr. Williams cries out that there is death in the pot, and tells us that one of the most deadly of inventions is the cooking stove; it destroys the vitamins, and it is the lack of these that is the cause of the all-prevailing constipation. Meats, sugars, and starches should be replaced, to the relief of the cookless housewife, by fresh fruits, raw vegetables, and unsterilized dairy produce. Afternoon tea—a stodgy assemblage of saccharine and starchy horrors—is severely pilloried. Bacteriology, the author says, has led to the habit of sterilizing everything, and the causes of cancer must be sought, not in the laboratory, but in the kitchen. Rickets, adenoids, and appendicitis were unknown before the microbe; the kettle and the crucible came to constitute a creed; and germicides have created diseases which had no existence before their advent. These, in the main, are the kind of messages which Dr. Williams delivers in his book to his "meat eating and sugar sucking," civilized but constipated compatriots. He is less iconoclastic when writing about alcohol. In fact, the lover of wines and spirits will get consolation and encouragement from him, for we are told that virile and vigorous nations have always been alcoholic, and that widespread cessation of drunkenness has always been followed by national degeneracy. The book ends with an injunction to the reader to remember that man's place in the scheme of things is among the animals, not among the angels. There is a certain amount of wise counsel in the book, and some amusement for those who do not take it too seriously.

#### NOTES ON BOOKS.

*Clinical Laboratory Methods*, by Dr. R. L. HADEN, gives a full description, supplemented by a large number of excellent illustrations, of all the standard methods in common use in clinical laboratories. The first edition appeared in 1923 (BRITISH MEDICAL JOURNAL, May 12th, 1923, p. 814), and the time since its appearance has been too short to necessitate any considerable changes in the textbook. The author has, however, brought it up to date, and the new edition<sup>3</sup> gives accounts of methods published as recently as last year. The most important change is the adoption of the Kolmer technique for the Wassermann reaction. Other new methods described

<sup>1</sup> *An X-Ray Atlas of the Normal and Abnormal Structures of the Body*. By Archibald McKendrick, F.R.C.S.Ed., D.P.H., and Charles R. Whittaker, F.R.C.S.Ed. Edinburgh: E. and S. Livingstone. 1925. (Demy 4to, pp. xvi + 222; 388 figures, 104 plates. 25s. net.)

<sup>2</sup> *The Science and Art of Living*. By Leonard Williams, M.D. London: Hodder and Stoughton, Ltd. 1924. (Cr. 8vo, pp. 240, 5s. net.)

<sup>3</sup> *Clinical Laboratory Methods*. By R. L. Haden, M.A., M.D. Second edition. London: Henry Kimpton. 1924. (Med. 8vo, pp. 310; 69 figures, 4 plates. 18s. net.)

for the first time are the Kramer and Tisdall method for estimating the calcium content of blood, and the van den Bergh test for bile pigments in the blood. The book is especially noteworthy for the full practical details it gives of the methods described; for example, five pages are devoted to methods of counting red blood corpuscles, and there are descriptions and illustrations of some very useful pieces of apparatus for shaking and cleaning blood pipettes. Details such as these are of great value to the laboratory worker, as they tend to lighten the drudgery of routine work.

The nineteenth edition of *Chavasse's Advice to a Mother* has been revised by Dr. G. T. WRENCH, past assistant master of the Rotunda Hospital, Dublin, who has brought the various subjects up to date. The chapters on infant feeding have been rewritten. As a guide to the management of children and the nursing required in accidents and illnesses the book fully maintains the high standard of previous editions; the style is simple and the advice practical. The reviser's advice to a mother to read through the book and not merely to use it as a reference in emergency is to be commended. Another praiseworthy feature is that no attempt is made to substitute written instructions for the personal supervision of a medical practitioner, as is too often the case in books of this nature.

The Minutes of the General Medical Council and of its Various Committees for the year 1924 have been published in a bound volume with eleven appendices. A detailed report is given of the two sessions of the General Medical Council and of the meetings of its various committees, together with those of the English, Scottish, and Irish Branch Councils. The presidential addresses of Sir Donald MacAllister at each of these sessions, which were published in our columns when delivered, are also printed here. Copies of the correspondence dealing with the regulations permitting foreign medical practitioners to practise in Italy are included, and the revised regulations for medical degrees in the University of Bombay are detailed. The General Index to the Minutes of the General Medical Council, and of its Executive and Dental Committees, and of its three Branch Councils from 1903 to 1924 has also been published. It relates to Volumes xl to lxi of the Minutes. The plan of the previous index has been followed closely, and each subject is indexed fully, the references being arranged chronologically; in many cases special subheadings have been inserted. This Index is a valuable book of reference to the proceedings of the General Medical Council and of its committees. Vol. iii of the Minutes of the Dental Board of the United Kingdom for 1924, which has also been received, has sixteen appendices containing the reports of various committees, tables of accounts for the year 1923, and rules for the conduct of elections under the Dentists Act, 1921. Warnings are given in one appendix as to covering, advertising to procure patients, and the use of titles and descriptions.

Three further numbers of *Ambulance Competition Tests* have been prepared by Dr. N. C. FLETCHER, dealing respectively with certain errors in treatment, the history of com-

The information is arranged as to be easily portable, and the series will be found of value by those responsible for devising competitions and examinations in ambulance work. A considerable amount of practical detail is set out in such a way as to encourage ingenuity in application. The first three of the series issued in 1923 dealt with the training of competition teams, the conduct of these teams in a competition room, and some common errors in competitions. The series forms a valuable adjunct to ambulance training of all kinds.

In a pamphlet recently published in Zürich<sup>19</sup> F. BRUPBACHER discusses the question of how far a medical practitioner contravenes the law by the practice of abortion, which is a criminal offence in Switzerland and elsewhere. He argues that, as the doctor's duty is to check disease processes and save the life of his patient, and as pregnancy has a harmful influence in cases of latent as well as active tuberculosis, cardiac and renal disease, anaemia and deafness, a pregnant woman who is suffering from any of these ailments should be relieved of her unborn child within three months of the beginning of pregnancy at latest. He produces from a considerable wide literature statistics and other facts in support of his contentions. Another aspect of his case is the need of saving the woman from the practice of abortion by

unqualified practitioners and quacks. In his opinion the qualified practitioner should be at liberty under the law to procure abortion whenever by doing so he can benefit the woman, but where eugenic considerations arise he favours sterilization of the mother. The pamphlet appears to be instigated to some extent by the strict laws on the subject in Prussia, where the object, according to Brupbacher, is to produce what he calls "revenge children" without regard to the life of the mother. The mother he considers to be of more importance than the three months old foetus, and the doctor is not carrying out his duty if he does not relieve her of what may exacerbate fatally or otherwise any disease from which she may be suffering.

In *The Quisto-Box*<sup>21</sup> the author has hit upon an ingenious idea for a novel. Professor Quist has succeeded in inventing a pocket instrument enabling its possessor to read the thoughts of anyone with whom he happens to be in conversation. At the moment when he has brought the machine to perfection he dies, and the story traces the efficacy of the box in the hands of the adventurous and attractive young woman who gets hold of it, and subsequently the terrible results that occur when the invention is commercialized and becomes available to all—results which culminate in the destruction of civilization. Incidentally the readers become spectators of a political crisis in a state of post-war creation which is to be understood to bear some relation to Palestine before the mandate was granted. This part of the book, really a digression, contains good descriptive writing. As regards the central idea of the Quisto thought-reading box, who will venture to declare in these days that there may not be "something in it"?

<sup>19</sup> *The Quisto-Box*. By Horace B. Samuel. London: A. M. Philpot, Ltd. 1925. (Cr. 8vo, pp. 234. 7s. 6d. net.)

## PREPARATIONS AND APPLIANCES.

### *Metallic Bismuth for Intramuscular Injection.*

The use of bismuth as a spirillicide in the treatment of syphilis is engaging a considerable measure of attention. The first compound of bismuth brought to our notice in this connexion was a salt having the chemical structure of tartar emetic, in which the antimony was replaced by bismuth. Our attention has now been directed to a suspension of metallic bismuth supplied for intramuscular injection. It is not a colloidal solution; it is merely a powder of the metal sufficiently fine to pass through a hypodermic needle yet so coarse as to recall the appearance of reduced iron. The metal is suspended in water containing 5 per cent. of glucose. It is prepared by the Boots Drug Company, Ltd. (Nottingham), and is supplied in rubber-capped phials containing five doses each. We have examined the preparation analytically and are satisfied as to its chemical purity. If bismuth should prove to be well tolerated in this form, it is not unreasonable to expect that the coarse suspension may provide for the presence of an inactive excess of the metal, presenting through its surface a continuous but moderated activity towards the blood stream.

### *An Aseptic Combined Dissecting and Artery Forceps.*

Dr. FRANCIS S. PITT-TAYLOR (Blackpool) writes: The forceps here illustrated is of two kinds, each having an externally rounded small end-of-egg-shaped jaw to permit a ligature to slip over the jaw on to the vessel easily, even when the forceps has been applied to a bleeding point at the bottom of a cavity or pocket as in abdominal operations; owing to this jaw shape the forceps when applied stands up on a slant instead of falling down flat, an advantage when the surgeon is working without a colleague in the application of the ligature, which can thus be rapidly and immediately applied to secure the bleeding vessel.

The bite of the serrated edge is of two kinds. One, the wider, B, is of the bull-dog type for larger vessels; its other extremity is rounded.

The other, the narrower, T, of the ferrier forceps type for smaller vessels, has a pointed opposite end so that when closed either forceps can be distinguished by their distinctive external shape.

The spring has been given a large head to permit of the easy removal of the forceps, whilst its attachment to the inner surface of one blade proximal to the jaw has a heel shape to permit of easy cleaning. The screw head usually visible on the outside of artery forceps has been dispensed with, no sign of its presence remaining in the completed instrument. Either forceps can be used as a dissecting forceps when required by grasping its sides above the position of the spring head, where pressure will not cause the spring to lock the forceps. Messrs. Mayer and Phelps, London, are the makers.

SATURDAY, MARCH 14TH, 1925.

## HEREDITY AND TUBERCULOSIS.

WHETHER an hereditary predisposition to fall a victim to clinically manifest tuberculosis is an etiological factor of importance has long been a vexed question. In recent times Professor Karl Pearson and his collaborators have been the chief exponents of the opinion that such a predisposition is both heritable and of importance. Put briefly, these workers have shown that the incidence of overt tuberculosis upon the ascendants of persons themselves diseased is greater than upon the ancestors of the same degree of kinship of normal persons. Upon certain assumptions it was possible to measure the intensity of the association between the liability to disease of the paired relations, and the resulting numerical value was of the same order of magnitude as that obtaining with respect to characters, such as stature, the statistical treatment of which was easier. It was objected to these researches that the resemblance between parent and child brought out might be interpreted as a measure, not of the force of inheritance, but of the force of familial infection. In rebuttal of this, it was shown that the numerical measure of association between husband and wife, with respect to the having or not having manifest tuberculosis, was much smaller than that connecting parent and child, although the opportunities for infection were as great or greater. To this it was retorted that the age factor in infection was so great that a study of husbands and wives did not really amount to a valid control.

There the matter has stood in this country, the parties to the dispute remaining (as usual) of their original opinions. The greater facilities offered by America for the compilation of some kinds of statistics have been exploited to obtain further evidence. Two recent statistical contributions from America, reaching wholly different conclusions, may be noted. The first is Dr. Raymond Pearl's study of constitution and tuberculosis, originally contributed to a symposium but forming a chapter of his new book *Studies in Human Biology*.<sup>1</sup> The other is a paper by Mr. Godias J. Drolet, entitled "The inheritance factor in tuberculosis," published in the *American Review of Tuberculosis* for November, 1924 (vol. x, p. 280).

Dr. Pearl is engaged in a large-scale investigation which is not yet complete, and is very careful to abstain from positive statements; but an illustration of his method may be given. "Suppose," he asks, "we stopped the first man or woman we chanced to meet on the street and ascertained by appropriate methods whether that person was or was not tuberculous, and at the same time made detailed inquiries as to his or her blood relatives. Should we be justified in laying a wager, if the individual proves to be tuberculous, that a larger percentage of his relatives will be also tuberculous than if he himself were non-tuberculous, and what, if any, odds could we give in

such a wager?" To get a first approximation to the answer Dr. Pearl studied 57 persons—38 tuberculous, 19 not tuberculous—the family histories of whom, covering 5,000 blood relatives, had been traced. He tabulated the proportions of the relatives in each generation who were or were not tuberculous. For instance, the parental generation (parents, uncles, aunts) of the non-tuberculous subjects included 763 individuals, of whom 14 (1.8 per cent.) were tuberculous; the parental generation of the tuberculous persons included 472 individuals, of whom 42 (8.9 per cent.) were tuberculous. Taking all generations together, 7 per cent. of the blood relatives of the tuberculous and 1.2 per cent. of the blood relatives of the non-tuberculous were themselves affected. Dr. Pearl then considered the opportunities of infection, dividing his data into (a) those known to have been in close contact with another case before developing the disease, (b) those not so known. He remarks: "As the amount of tuberculosis in the direct ancestry increases, the amount of tuberculosis in the offspring increases also, but the disturbing fact is that the rate of close contact with open cases increases enormously more rapidly than does the rate of incidence. In short, we find that where one or both parents are actively tuberculous, practically all the offspring who subsequently develop tuberculosis have been in close, intimate contact with another active case, usually, of course, that of the parent or parents. Instantly those who oppose the view that constitution plays any part in the etiology of disease, and particularly of tuberculosis, will assert that this explains the whole matter—that if the children had not been in contact with the open, active cases, they would not have broken down with the disease. Just possibly they may be right. The case, however, is not simple. Our figures equally show that where one or both of the parents were actually tuberculous, *virtually three-fourths of the non-tuberculous offspring have been in just as close contact with active open cases as their brothers and sisters who unfortunately developed the disease.* [Italics in original.] And it must not be supposed that this high contact percentage can be explained by asserting that the non-tuberculous children are all young children who will subsequently all develop the disease. This is not true. Their average age is significantly the same as that of the tuberculous offspring." He strongly emphasizes the need for multiplication of such data, and abstains from drawing conclusions, going no further than to suggest that the data are congruent with the view that familial infection is a real factor but does not wholly explain the increased incidence of tuberculosis in the direct ascending line of the tuberculous.

Dr. Pearl's paper is, we think, a good example of serious statistical field research. We are afraid this cannot be said without qualification of Mr. Drolet's essay. Mr. Drolet suffers from the weakness of the legendary sailor's parrot: he talks too much, as his first sentences sufficiently demonstrate. "The theory that tuberculosis is inheritable dies hard. As the original protagonists of that idea have been driven, because of lack of evidence, from a belief in the actual transmission of the disease from mother to child, they have retreated into the position that, if the disease itself be not inherited, then at least a predisposition to it is transmitted." The position which the "original protagonists" "have retreated into" is the grave, which one of them has occupied for more than a thousand years. But it is to be hoped that Mr. Drolet's friends will persuade him to eschew eloquence, and temporarily abstain from speculating on "Nature's powers of

<sup>1</sup> Baltimore, 1924.

resistance and recovery," so that he may have more time to devote to statistical analysis, since he puts forward some data which may be worth careful study.

Mr. Drolet has, apparently, inquired into the family histories of a large number of persons suffering or not suffering from clinical tuberculosis—5,998 adults and 1,431 children. Of the adults, 3,759 were suffering from tuberculosis, 2,239 were not. In the tuberculous series a parental history of tuberculosis was obtained in 432 instances, or 11.5 per cent. of the cases; in the non-tuberculous series positive histories were obtained in 321 instances, or 14.3 per cent. of the cases. Of the 1,431 children, 244 were tuberculous, 1,187 not tuberculous. The percentages of positive family histories work out as 55.7 for the tuberculous and 60.3 for the non-tuberculous. Mr. Drolet has himself set out the data as percentages of the offspring of tuberculous and non-tuberculous parents, reaching the result that 57 per cent. of the adult offspring of tuberculous and 63 per cent. of the adult offspring of non-tuberculous parents are tuberculous, the corresponding figures for children being 13 per cent. and 22 per cent. As, however, the sampling is of the filial, not of the parental, generation, this method of presentation is, we think, erroneous; knowledge of the parents was obtained through the children; but the results, when correctly stated, are so curious that they deserved fuller analysis. We do not think it has been suggested before that the children of the tuberculous are less likely to develop the clinical disease than the children of the non-tuberculous, or, to use Dr. Pearl's analogy, that we might lay odds that the proportion of tuberculous ascendants in the line of a person suffering from tuberculosis is smaller than in the line of a person not suffering from tuberculosis. Mr. Drolet has, indeed, a theory to account for this. He finds that the prognosis in sanatorium treatment of patients with a history of tuberculosis in the family is rather better than that of those without such a history, and holds that "Nature" works by the immunizing of the descendants of the tuberculous. He is, we think, mistaken in supposing that Professor Pearson "felt the existence of some such possibility"; we do not know, of course, but we suspect that in the passage cited from Professor Pearson that investigator may have been referring to an English writer of some note in his day—the late Charles Darwin. But we certainly think that a fuller analysis of Mr. Drolet's material should be prepared; because statistics look odd is no reason for rejecting them, but a very good reason for scrutinizing them closely. We suspect—basing ourselves on experience of the difficulty of securing accurate family histories of disease—that the specifications of both numbers and state of health in the parental generations are incomplete, and that Mr. Drolet is dealing with much less adequate material than Dr. Pearl. When this important point has been cleared up will be time enough to discuss Mr. Drolet's theory of hereditary immunization.

We have thought it worth while to refer to these papers at some length because there is a fairly obvious tendency in recent literature to ventilate very far-reaching theories of etiology in tuberculosis without producing any evidence which will bear critical evaluation. Some very distinguished investigators, such as Professor Calmette, are not wholly free from reproach in this matter, and unless the tendency is checked knowledge of etiology will not be increased, but the very modest existing standard of medico-statistical accuracy will be lowered. As matters now stand, the caution of Dr. Pearl rather than the speculative ingenuity of Mr. Drolet should be the guide of workers in this field.

## INFANTILE PARALYSIS.

THE disease described by Medin and Heine, and long known as infantile paralysis, has become more and more important during the last thirty years. As our knowledge of its incidence and pathology has increased the descriptive inadequacy of its title has become evident. The original name became obviously inappropriate as soon as it was recognized that the disease sometimes affected adults, whereupon the pathological name of anterior poliomyelitis was substituted. Later still—when it was established that in some of the cases observed during epidemics lesions were found in other parts of the central nervous system, and symptoms were recorded which betokened affections of the cerebrum—it became necessary to make its name more comprehensive, and writers such as R. W. Lovett adopted the cumbersome title of anterior poliomyelo-encephalitis. Until 1894 no extensive epidemic of the disease had been accurately recorded, but in that year Caverly reported 132 cases in the course of a few months in the New England State of Vermont. Since then there have been thirteen epidemics of sufficient importance to be tabulated by Jones and Lovett in their recent work on orthopaedic surgery, culminating in the really appalling outbreak of 1916 in the City and State of New York, in which 13,223 persons were attacked, and the death rate was over 25 per cent. These thirteen epidemics comprised over 18,000 cases, with an average death rate of 20.7 per cent. Although complete recovery occurs in perhaps one-fourth of the survivors, the remainder are the victims of lifelong disability in a greater or less degree. The infectivity of the disease has been established beyond doubt, although the micro-organism concerned is a filter-passer which has not been isolated. In this country the disease is notifiable, but as it is almost certainly propagated by unsuspected "carriers" attempts to control it by isolation are not very likely to be successful.

No acceptable explanation has yet been offered of the localization of epidemics of anterior poliomyelo-encephalitis, and no good reason can be assigned for their prevalence in the north-eastern States of the Union. Besides those localities, the Scandinavian peninsula and Central Germany have been sufferers. No epidemic of importance has been recorded in Great Britain, Ireland, or France, yet the frequency of sporadic cases and small epidemics in these countries shows that the conditions in them are not prohibitive, and that we must not count on the continuance of our comparative immunity. Therefore we should set our house in order and be prepared for eventualities. The cripples' organization which started in Shropshire, and which is spreading all over the country, should provide the cadres for mobilization in case of attack by a formidable epidemic. In London the County Council has a scheme on foot for the provision of hospital treatment for cases occurring within its area.

Enough has been said to show the gravity of the problems presented by this disease and to justify Mr. E. W. Hey Groves in choosing its treatment as the subject for his address to the Dorset Medical Society, which appears in another part of this issue. The principles, and the application of them which he so strenuously advocates, are accepted by all orthopaedic surgeons and those physicians and other practitioners whose lot it has been to acquire adequate acquaintance with this disease. For many years orthopaedic surgeons have had the satisfaction of correcting paralytic deformities by various means, including the application of instruments, and of enabling cripples

who may have appeared doomed to hopeless inactivity to stand erect upon their feet and to move about. But it has been seldom that the surgeon saw a case in its early stage, or even before contractures and secondary joint and bone distortions had supervened. Some physicians, notably the late Dr. F. E. Batten, utilized their opportunities of treating cases in their early stages by inculcating the necessity of prevention of deformity by the use of celluloid or other retentive appliances; but until recent years the early treatment has been too often, on the one hand, harmfully meddling in its attempts at stimulation, or, on the other hand, negligent of the means of preventing secondary changes in bones and contractures of joints.

The disease, Mr. Hey Groves reminds us, has for convenience been described as consisting of three stages, but, strictly speaking, there are only two—namely, the initial inflammatory stage, and the longer stage during which recovery is taking place in those nerve cells which have not been irretrievably damaged. In the so-called third stage no active morbid process is going on, but the effects of previous active disease remain permanently. Everyone with any experience agreed that in the first two stages complete physiological rest is imperatively called for. In the less severe cases—in which, for instance, one leg and foot only are obviously affected—the first stage may be so transient as to escape notice by untrained observers. Many parents in the out-patient room have declared that there was no sign of malaise or fever, but that the child "went to bed well and woke up paralysed." Such was the history given in 19 out of a series of 115 cases recorded in a paper read by Mr. Muirhead Little at the Annual Meeting of the British Medical Association at Ipswich in 1900,<sup>1</sup> while in many others no history of constitutional disturbance could be elicited. His experience suggests that although early recognition and treatment is most desirable, there will often be practical difficulties in their attainment. It is therefore all the more necessary that every practitioner should bear in mind the importance of watching carefully any symptoms of malaise occurring in children during the third quarter of the year, in which season the majority of attacks occur, and of prescribing complete rest as a precautionary measure. As soon as the diagnosis of poliomyelitis is made, the measures of restraint specified by Mr. Hey Groves and other writers must be employed. Later on the specialist will probably be called upon to perform such operations as may be necessary to enable the patient to make the best use of so much muscular power as remains to him and to minimize the need of mechanical supports, which, however, can never be entirely dispensed with in severe cases. But neither the general practitioner nor the specialist can do his part of the work unless the necessary clinics and hospitals are provided. Early notification in the active stages of the malady ought to connote the provision of the necessary beds in isolation hospitals or wards of hospitals, while for the crippled stage it is most desirable that the hands of the Central Committee for the Care of Cripples and of the administrative authorities responsible for orthopaedic and cripples' hospitals should be strengthened by the provision of ample funds by the charitable public, in which should be included not only the rich, but also those agencies which enable the working man to take his part in charitable work.

Mr. Hey Groves concludes his address with a slashing attack upon British hospitals in general and the voluntary hospitals in particular. There is, he

says, "striking evidence of the failure of the voluntary system." Slashing attacks are a sign of vigour, and they commonly have results—either the destruction of an untenable position or the impalement of the attacker. Mr. Hey Groves's attack is based upon his failure to get what he wants for his patients. He wants special institutions, "open-air hospitals," for those who have passed the acute stage of infantile paralysis, where they can be treated for years. Proof that his demand is justified is to be found in his own words: "Such open-air school hospitals have been springing up all over the country, chiefly as the result of individual philanthropy and enterprise." Strangely enough, he confesses that he is getting the thing he wants, and partly through the very voluntary system he condemns so bluntly. Much of his condemnation is based upon a misconception common to many writers and speakers. There is a hospital system in this country—a patchy mosaic established by statute under various authorities. There is no voluntary "system," though there are many voluntary hospitals—the expression of "individual philanthropy and enterprise" (to use Mr. Hey Groves's words). At diverse times and in various places men and women, moved by the spirit of the Good Samaritan, have given of their skill, time, and substance for their stricken neighbours. The appeal has arisen in many different ways, but it has always been swiftly answered. The fever-stricken, the leper, the outcast, the infirm, the woman in child-bed, sick children, and the child paralytic have all made their piteous appeal, and the generosity of the philanthropist and doctor has always and quickly answered it. The fact that now in this country the beds in "State" hospitals vastly outnumber those in "voluntary" hospitals is in itself proof of the success of the voluntary principle; it means that "individual philanthropy and enterprise" has compelled the sluggish mass of the community to follow suit. That Mr. Hey Groves has not all the open-air school hospitals he wants shows chiefly that the local education authorities are not carrying out duties which are properly theirs. It is evident from this that the mass movement has not yet been drawn into the wake of the individual pioneers. But perhaps he is writing of Bristol only, for there are parts of the country where the advance has been much greater.

A phrase in Mr. Hey Groves's paper suggests that he is not familiar with the policy of the British Medical Association for the co-ordination of hospital services. It has just been published in a separate pamphlet,<sup>2</sup> and is worth study. Perhaps through that scheme we shall be able to combine the swift response of voluntary or independent enterprise with the mass of communal action, to the general advantage.

The fifth British Congress of Obstetrics and Gynaecology will be held at the house of the Royal Society of Medicine, 1, Wimpole Street, London, W., from April 22nd to 24th inclusive. The president is Dr. H. Russell Andrews, and the honorary secretaries Mr. Clifford White and Dr. J. D. Barris. The subjects to be treated include the prognosis and treatment of puerperal sepsis, and endometrioma. The members of the Congress will be entertained to lunch by the Section of Obstetrics and Gynaecology of the Royal Society of Medicine; an evening reception and a dinner will also be held. The detailed programme will be issued at the beginning of April.

## THE PRESCRIPTION OF MANGANESE.

LITTLE prominence has been given to compounds of manganese in works on materia medica, and no extensive therapeutic use has been made in this country of pharmaceutical products from it. Its compounds fall into two classes: one is represented by salts of the type of manganese sulphate or chloride; the other comprises the group of permanganates, and includes the higher oxides, which have a more pronounced character as vehicles of chemically active oxygen than of medicinal manganese. Manganese sulphate has appeared in a list of purgatives, the dose ranging from 30 to 60 grains; in that character a similarity is evinced to its crystalline isomorph magnesium sulphate. It has also been accounted a tonic when given in doses of 1 to 5 grains; in this respect it bears comparison with ferrous sulphate, with which it is also isomorphous. Manganese hypophosphite is an ingredient of compound syrup of hypophosphites (*B.P.C.*). The expectation that manganese would be rendered more readily absorbable when combined with protein has led to the preparation of a nucleinate; a colloidal solution of the dioxide has also been prepared for medicinal use, and manganese butyrate has been used for intramuscular injection. The uses of potassium permanganate are very well known. It has been generally regarded as having only a local action. Since, however, the view is now established that manganese plays an important part in metabolism, it may not suffice to assume that the beneficial effects of certain modes of treatment by permanganate can be attributed solely to local action; consequences of absorption and assimilation must also receive attention. The interest—some evidence of which is afforded by the letters published elsewhere this week—aroused by Dr. H. W. Nott's paper (published last week, p. 443) on the effects of rectal injection of permanganate accompanied by administration of products of the thyroid gland, will stimulate the desire for a preparation to be given by the mouth which shall produce like effects. It will be helpful, in following this aim, to have a careful appreciation of the conditions of the treatment adopted by Dr. Nott. When permanganate is injected into the rectum three actions can be recognized: first, a vigorous oxidation acting selectively on those matters most susceptible of oxidation with which it comes in contact; secondly, the production of manganese dioxide or even a lower oxide in a condition capable of being absorbed; and thirdly, the formation of caustic alkali. Three grains of potassium permanganate produce a grain of caustic potash—an action of doubtful advantage, for certain mucous surfaces are highly sensitive to caustic alkali, even when it is much diluted. This may perhaps account for the mucous casts of the bowel passed by some of the patients treated by rectal injection. Since the manganese salts belonging to the first mentioned group have no oxidizing power, it is evident that none of them could supply the oxidizing activity of permanganate. Permanganate itself undergoes immediate decomposition when given by the mouth. It is, however, not improbable that both the other activities of permanganate, provisionally regarded as desirable, may be realized in adequate degree by the administration of manganese dioxide by the mouth, especially if it be given in a form that would pass to the bowel with least intermediate change. Manganese dioxide possesses an oxidizing power which is less vigorous than that of permanganate, but it is nevertheless effective on matters susceptible of oxidation. Camesease, whose successful use of manganese in debilitated children was noted in the leading article published last week (p. 468), prescribed manganese binoxide in cachets or compressed tablets given by the mouth. His formula in English equivalents is manganese dioxide gr. xiv, magnesium carbonate gr. xx, magnesium peroxide gr. v, diastase gr. i, gum, sugar, essences q.s. These

quantities yield fourteen doses, dispensed as compressed tablets, each containing a grain of manganese dioxide. English authorities give variously, some 5 to 10 grains, and others 10 to 30 grains, as the permissible dose. Manganese dioxide is not included in the *British Pharmacopoeia* as a medicine; it appears there only as a test reagent. There are two kinds: One is natural; it occurs chiefly in the form of pyrolusite, consisting of steel-grey prismatic crystals, and in the amorphous mineral psilomelane, a black powder. The natural product contains more or less iron oxide, calcium carbonate, and earthy matter. The other kind is obtained by precipitating a solution of manganese by means of ammonia and hydrogen peroxide and repeated washing. Both are described in the *Pharmaceutical Code*, but only the precipitated powder is there mentioned as suitable for internal administration. The natural article may, however, probably be preferred for the purpose now in view, for the precipitated, being more active, is less likely to reach the bowel unchanged. The natural kind can be rendered pure for medicinal use without alteration of its character; if no other but the precipitated is available, it could be rendered less speedily changeable by the simple process of ignition. Manganese dioxide may be conveniently administered alone in cachets or pills, the dose being varied, according to progress, between the limits above indicated.

## SCHOOLS AND EPIDEMICS.

THE Ministry of Health and the Board of Education have jointly issued a revised memorandum on the closure of schools and the exclusion of children from them.<sup>1</sup> The previous issue was in 1909. In an introductory note it is pointed out that hitherto local education authorities have been able to close schools during epidemics, not purely in public health interests, but for reasons of finance, so as to save loss of grant from diminished attendance. That statement amounts to a frank admission of mistaken policy on the part of the central authorities, and it is good that they have seen the wisdom of departing from it. The primary purpose of the school being education, it was wrong to make it possible for local bodies to profit financially by complete school closure rather than exclusion of pupils where the latter measure would be equally efficacious in checking spread of disease. The code now provides that closure shall take place only for medical reasons, and that authorities shall be secured from financial loss when schools are kept open with a greatly diminished attendance. Though in other respects the new memorandum does not differ essentially from that of 1909, attention is directed to certain changes and additions. These relate (1) to the rules as to periods of exclusion necessary for scarlet fever, diphtheria, measles, and mumps; (2) to rules for action in respect of small-pox, German measles, influenza, and epidemic diseases of the central nervous system, which have now increased in prevalence; (3) to action required where teachers are found suffering from pulmonary tuberculosis; and (4) an appendix giving in summary tabular form the incubation and exclusion periods of the commoner infectious diseases. After detailing the powers of local authorities, the memorandum goes on to give guidance for the co-ordination of the work of the school medical service with that of the public health service in respect of school closure, which is to be resorted to as seldom as possible, and the exclusion of children, which is very generally the more advisable course. The sanitary and educational authorities are the same in county boroughs and in some municipal boroughs and urban districts, so these may have the same officer for both purposes, who, it is advised, will generally find it more convenient to deal with closure and

<sup>1</sup> Copies may be obtained from H.M. Stationery Office or through any bookseller, price 4d. net.

exclusion as school medical officer, because, if the Board is satisfied with arrangements made locally, the officer can authorize exclusion directly, without reference to his authority, while, as already insisted, where he can only advise, not authorize, school closure should be rare and exceptional. Where there are two separate officers—one for education, the other for public health—the same considerations apply generally, though the responsibility of the latter officer for dealing with outbreaks of infectious disease is not diminished by the powers of the former, and definite working arrangements should be established on lines laid down in the memorandum. The collection of information about infectious disease among children will depend mainly on the medical organization of the local education authority, which can systematize the work of teachers, school nurses, and attendance officers, as well as get information from parents. Of these agencies that of well trained nurses is the best, by visits both to schools and to homes of absentees. Where the medical officer holds a joint appointment the information should go to him; elsewhere the health officer should be the first recipient, and transmit the information promptly to the school medical officer. Infection is spread much more by persons than by things, so that besides disinfection, cleanliness, and ventilation of school premises, special regard is to be given to children of infected households as possible carriers, and unrecognized cases may be sought for among children who have returned to school after a short absence. Exceptional conditions sometimes justifying school closure include infectious sickness in the teacher's family, the need for disinfection and cleansing after infected children have been in attendance, the rectification of sanitary defects; whilst in rural areas with scattered population the school may give the only likely opportunities for intercourse and so may be properly closed. Sometimes it suffices to close, not a whole school, but a department. An important section of the memorandum deals with rules for action in respect of particular diseases—scarlet fever, diphtheria, measles, and others—but the details are too numerous for synopsis here. Epidemic diseases of the central nervous system are referred to last of all, and though the guidance that present knowledge permits is limited in amount, yet what is said will no doubt be carefully studied. The whole memorandum will now be essential for reference by every health officer and school medical officer in the country. It is, moreover, well worth perusal by education authorities in general. It is signed by Sir George Nowman on behalf of the Board of Education and the Minister of Health.

#### THE BACTERIOLOGY OF CANCER.

Some pathologists are reverting to the belief, once very generally held, that cancer is due to infection by some extraneous organism. On analogical grounds there is much to be said for this view, and investigations in this direction undoubtedly deserve encouragement. One of its chief exponents in this country is Dr. James Young of Edinburgh, who summed up the grounds on which he has arrived at this opinion in a paper recently published in our columns (January 10th, 1925, p. 60). He described an organism possessing a series of phases—yeast, coccoid, bacillary, and amorphous—each of which could grow true to type and live a wholly independent life. He advanced evidence which satisfied him that the parasite lives in symbiosis with the cancer cell in the amorphous phase. The parasite, he said, belonged to familiar bacteria widespread in nature, and expressed the opinion that the ease with which cancer could be produced experimentally in animals by chronic irritation suggested that tissue susceptibility, which he also concluded must exist, implied an immediate risk of infection by a ubiquitous organism. Last year (June 21st, p. 1105) we gave some account of a

micro-organism isolated by Dr. T. J. Glover, formerly of Toronto, who claimed to have produced cancer in animals by its inoculation. He claimed also to have produced a serum with which he obtained favourable results. At that time Mr. R. J. Willan, who had then recently visited the United States, and to whom we were indebted for recent information, told us that he had heard of several successful cases, but was of the opinion, in which we concurred, that the claims made by Dr. Glover and his colleague Dr. Scott must be received with caution until a full disclosure was made. Dr. London and Dr. James M. McCormack, physicians to St. Michael's Hospital, Toronto, published in a recent issue of the *Canada Lancet and Practitioner* (January, 1925) some observations they had made regarding the isolation, culture, and identification of the organism described by Dr. Glover. They had visited Dr. Glover's laboratory in New York, and had afterwards carried out a number of independent experiments and had cultivated an organism which they considered to be identical with that described by Glover. They insist upon its pleomorphism and recognize three distinct states of the life-cycle—bacillus, coccus, and spore sac. They also state that in one phase the virus passed through a Berkefeld filter, and that the filtrate yielded positive cultures when incubated at 37° C. for two days. They consider that their organism is identical with Glover's, and Dr. James Young informs us, in a letter recently received, that he considers that both are probably identical with his. He adds an expression of his belief that the cancer parasite can be understood properly only when considered in the light of recent work in bacterial variation, especially that of Lönnis and others. He concludes that a number of parasites may possess filterable, coccoid, bacillary, hyphal, and yeast phases. He also calls attention to recent investigations by Blumenthal, Auler, and Meyer of Berlin, who have obtained from different types of human malignant tumours a bacillus which they believe to be akin to the *Bacillus tumefaciens*, the cause of crown-gall in plants (Erwin Smith). By injecting this organism of human origin they have produced in the sunflower tumours indistinguishable from the typical crown-gall growth. Its injection into animals was followed in only two cases by a malignant growth at the site of inoculation. When accompanied by an irritant, however, employed for the purpose of preparing the tissues for the operation of the organism, malignant growths were produced at the site of inoculation in a considerable number of animals, and, in some, the microscopic malignancy was confirmed by the occurrence of metastases and by the fact that the tumours grew after transplantation to other animals of the same species.

#### TESTS OF PHYSICAL EFFICIENCY.

LIEUT.-COLONEL C. B. HEALD, M.D., medical adviser to the Department of Civil Aviation, Air Ministry, has visions of a newer medicine, in which the conventional methods of physical diagnosis will be scrapped. In the address which he delivered lately before the Royal Aeronautical Society he ventured to prophesy that we shall be able, by other than the conventional methods, to estimate with a high degree of scientific accuracy the physical well-being of any individual, to forecast where his barriers against possible disease are weak, and, by taking timely precautions, to strengthen them and so increase the chances of a prolonged and healthy life. It is through the science of aviation that this newer medicine will be realized, for it is presenting new problems in estimating physical efficiency, and teaching new facts regarding the mental and physical well-being of the individual. It is in words such as these that Dr. Heald concluded an address which throughout contained points of interest. He told his audience that the object of the

medical test of a pilot is not so much the detection of disease as the estimation of his degree of well-being. While they enable the medical examiner to diagnose disease in its most preventable form, they also enable him to advise the pilot how he may retain his fitness or regain it if it is deteriorating. Like Oliver Wendell Holmes's one-hoss shay, the pilot breaks down but does not wear out. The medical tests detect the weak points in the machinery before the breakdown occurs. Centralization of the periodical medical examination of pilots, of apparatus and accommodation, and of a system of graphic and other records, is therefore essential, at any rate at present, for accurately comparing changes in physical efficiency. The tests as a whole are designed to assess the basic physical standard of the pilot, to estimate his ability in the air, and to indicate the effect of his ground life on his basic physical condition. Three of the tests—namely, the exercise tolerance test and the blood pressure and vital capacity measurements—are "habit detectors." Together they give useful information as regards the pilot's habits on the ground with reference to exercise and overindulgence in food, drink, and tobacco. Dr. Heald also described three new testing apparatus—the Tucker auditory testing apparatus for recording accurately the power of hearing, the heart recoil apparatus for testing the ability of the heart to withstand the strain of long flights in bad weather, and the Reid control apparatus for assessing the manner in which the delicate co-ordinated physical machinery involved in flight is likely to function. These new tests illustrate how air medicine is endeavouring to improve the technique of medical examinations, and appear, indeed, to have given Dr. Heald his visions of a newer medicine. In the course of his address he made some sound practicable suggestions for establishing confidence between employer, the pilot, the public, the insurance companies, and the Government in connexion with passenger traffic in the air, and also remarked on the difficulties of maintaining a high degree of sanitation in the passenger car, especially in connexion with ventilation and air-sickness. The provision of first-aid boxes in passenger machines and ambulance services in aerodromes was also touched upon.

#### THE CONTROL OF THE TSETSE FLY.

Though *Glossina palpalis* is best known to the medical profession because it is the chief carrier of sleeping sickness, the cattle tsetse presents an even more formidable problem, owing to the vastness of the areas of which they effectually hamper the development. In *Nature* last week Mr. C. F. M. Swynnerton, in charge of tsetse work in Tanganyika Territory, described a scheme of control which had been inaugurated in Tanganyika Territory, and urged that, if the attack on the tsetse is to be made in the most economical and effective way, the main measures must lie in the diversion and regulation of agencies already in existence. The natives must be taught to understand and take part in the solution of their own problems, and existing agencies, such as the annual grass fires, must be harnessed. Tsetse flies are dependent on the presence of "bush." Certain native tribes have adopted a mode of settlement whereby, through the presence of sufficiently closely dotted villages with their chopping for firewood, building, and cultivation, and the browsing of their numerous stock, the bush is kept down and the "fly" excluded. By encouraging this form of settlement everywhere segregation will be extended and, for practical purposes, a control of the fly will be obtained. This concentration of organizable population, Mr. Swynnerton considers, is a necessary preliminary to all measures of a large nature against the tsetse in the bush; that is to say, reclamation must be undertaken. When one of these settlements comes into being its members should be helped to possess themselves of

cattle—for only cattle will "anchor" them permanently—and should be encouraged to push back the "fly" in conformity with their requirements. This will be done by an annual clearing of bush. The process has been begun in Shinyanga with the co-operation of the natives, and satisfactory results are already apparent. Clearing must be systematic, otherwise the stumps send out shoots and the position becomes worse than ever; methods of encouraging the removal of stumps and otherwise of killing woody growth are being experimented with. Increase in the population of the settlements should be encouraged by means of propaganda in hygiene, and the extension of the settlements be so guided that they would ultimately coalesce and cut off blocks of fly-infested bush, which, through their smaller size, could be attacked with more hope of success than the huge unbroken "fly-belt." Various methods could be applied to the blocks or smaller fly-belts. Swynnerton favours especially destruction of the thickets, which afford a breeding-place for most species of fly and a refuge for all during the annual grass fires; he would postpone the latter to the end of the dry season, when their lighting should be organized. Last year these organized fires drove the flies before them in great numbers into unburning thickets and patches of country burned previously, and it is suggested that in these places they could be exterminated merely by catching on a great scale. The fire also burned numbers of small breeding thickets, and killed, it appeared, many of the pupae of the flies. Father Cirvegna, a missionary, is believed to have cleared of fly a smaller area in three burnings. As regards game, the view is held that, while here and there the checking of particular movements of game animals may be necessary, no one wishes to exterminate the wonderful African fauna if the tsetse fly can be controlled otherwise, and that the initial work in Tanganyika leads to the very strong hope that it can. Swynnerton holds that knowledge of how to fight the tsetse can now best be advanced by taking a definite large area or entire territory and applying to it all knowledge that has been or will be acquired, by means of reclamation officers working hand in hand with research officers. These men would be trained in the field at the stations first established, and many would pass thence to other parts of Africa in order to make the campaign general. A large fund would be needed for this gradual development of large-scale experimentation in actual control under all African conditions; at the stage now reached that is the right method of research.

#### CHLORINE TREATMENT OF CERTAIN INFECTIONS.

The use of chlorine in the treatment of respiratory disease has been studied by Lieut.-Colonel E. B. Vedder and Captain H. P. Sawyer, of the Medical Corps of the United States Army, and a few months ago we gave an account of their first report.<sup>1</sup> In a further report, recently published,<sup>2</sup> they produce a certain amount of additional evidence in support of the therapeutic value of the gas, and discuss at some length the mode in which it may be supposed to act. They state that of 85 cases of coryza treated by them during June, 1924, cure resulted in 60, 22 were improved, and there was no change in 3. In acute bronchitis 6 out of 9 patients were cured and 3 improved, while in acute laryngitis 2 out of 6 patients were cured and 4 improved. The remedy was less successful in chronic bronchitis and whooping-cough. In the former only 2 out of 12 patients were definitely cured, and in the latter 4 out of 21; the number improved in each case was 10. The authors now agree that sterility of the mucous surfaces following the therapeutic use of chlorine cannot be expected, though many bacteria are doubtless killed. They think, therefore, that the clinical improvement can be better explained as

<sup>1</sup> BRITISH MEDICAL JOURNAL, December 27th, 1924, p. 1266.

<sup>2</sup> Journ. Amer. Med. Assoc., January 31st, 1925, p. 361.

follows. The irritant action of chlorine stimulates the lymph flow and cleanses the mucous surfaces, destroying large numbers of organisms, some of which may even be brought up from the depths of glands and crypts. In whooping-cough the beneficial effect is attributed to the loosening of the masses of tenacious mucus, which are then expelled more readily. They state that irritants such as chlorine cause a primary brief capillary constriction, followed by protracted dilatation, which produces hyperaemia of the affected mucous membranes; this aids recovery by improving the blood supply and increasing the number of polymorphonuclear leucocytes. The best therapeutic results were given by a chlorine concentration between 0.009 and 0.015 mg. per litre. This must be maintained for one hour; failures follow any excursions outside these limits. An apparatus has been devised to deliver the proper concentration of chlorine constantly and automatically. The gas generated by the electrolysis of hydrochloric acid is mixed with air in a box and delivered at the rate of 10 to 12 cubic feet a minute. The patient breathes the mixture through a funnel-shaped bag of muslin, applied loosely to the nose and mouth; re-breathing into the bag is avoided. Chlorine rooms have been designed for use in large hospitals, and for the treatment of animals. The authors state definitely that hay fever, asthma, pneumonia, and tuberculosis have not been benefited by this treatment, and are to be regarded as contraindicating its use. A few patients showed unusual susceptibility to the gas, and in them the length of treatment was reduced. An infant of 3 months with whooping-cough made a good recovery after being treated on four separate days, and several patients aged from 75 to 85 with chronic bronchitis obtained considerable benefit. The authors believe that chlorine treatment will prove to have a prophylactic value, and that treatment of early cases of influenza, whooping-cough, or similar infections will result in preventing epidemics from occurring in regiments, schools, and industrial establishments. Benefit is reported also in distemper in dogs, and an epidemic of influenza in horses was cut short. So far, however, no confirmatory evidence of the value of chlorine treatment has been published by other investigators working on a large scale.

#### THE EDUCATIONAL VALUE OF THE SANITARY SURVEY.

THE second series of the Rockefeller Foundation's publication *Methods and Problems of Medical Education*,<sup>1</sup> issued by its Division of Medical Education under the direction of Dr. Richard M. Pearce, differs considerably from the first series, which was reviewed in our columns (1924, ii, 1014). Instead of dealing, as the opening number did, with several different subjects, this instalment confines its attention to the sanitary survey as an instrument of instruction in medical schools. Dr. Milton J. Rosenau, professor of preventive medicine and hygiene in the Harvard Medical School, Boston, discusses this problem in a comparatively short paper, and the rest of the volume is devoted to the sanitary survey of Rochester, New Hampshire, by Mr. Shields Warren when he was a third year's student in the Harvard Medical School. Professor Rosenau confines his remarks strictly to the use of the sanitary survey as a method of instruction in medical schools, and leaves entirely out of consideration for the time the teaching of preventive medicine, hygiene, and sanitation. To arouse interest is a basis of successful teaching, and the sanitary survey brings interest to a subject which the ordinary medical student regards as having but little bearing on his life's work. It was first used as a method of instruction in the School for Health Officers at Harvard, and met with such signal success that

it was introduced later into the course in preventive medicine and hygiene. Every student working for a medical degree is required to make a sanitary survey of some city or town, and submit a report containing (a) the collected data, (b) the interpretation of the facts, and (c) criticisms and recommendations. The student is told to regard the town that he is surveying just as he would a patient, but is not given any special instructions, since it is considered desirable to bring out powers of initiative, observation, and analysis. A small place is more suitable than a large one for such a sanitary service, and Boston is fortunate in having fifty-two towns within fifteen miles of the State House. All the Harvard medical students carry out these surveys, often in the vacations, and apparently the authorities of the surveyed towns sometimes come to recognize their deficiencies, and have employed the surveyors to organize a health service. The surveys are all filed in the Harvard Medical School. Mr. Shields Warren's survey of Rochester, New Hampshire, is reproduced without correction and with its photographs, graphs, and tables.

#### VITAMIN DEFICIENCY.

THE Royal Society of Medicine (as reported in our issue of February 21st, pp. 358-9) recently held a general meeting to consider the non-specific disturbances of health due to vitamin deficiency. The four opening papers were so full and so interesting that there was little or no time to discuss them. But so many present expressed the desire to debate the subject fully that the society is holding a further meeting on Monday, March 23rd, at 5.30 p.m. The subject will again be opened by Dr. Leonard Williams, Colonel Robert McCarrison, Dr. W. Cramer, and Dr. G. M. Findlay, with an epitome of their opening speeches and lantern demonstrations. But the original speeches can be read in full in the March number of the society's *Proceedings*, and those who wish for a summary can obtain galley slips on application at the society's office, 1, Wimpole Street, W.1. The general discussion of these papers will be opened by Dr. William Hunter and Dr. Robert Hutchison.

#### VENEREAL DISEASE: DEPUTATION TO THE MINISTER OF HEALTH.

LAST week the Minister of Health, who was attended by the Chief Medical Officer, the Secretary of the Department, and other technical advisers, received a joint deputation from the National Council for Combating Venereal Diseases and the Society for the Prevention of Venereal Disease. In the absence of Lord Trevethin, president of the National Council, the deputation was introduced by Sir Auckland Geddes, G.C.M.G., M.D., president of the Society, acting on behalf of both bodies. Sir Auckland Geddes stated the case on the lines agreed by the joint conference of the two societies, and supported the recommendation contained in Clause 14 of the Trevethin report: "That the law should be altered so as to permit properly qualified chemists to sell *ad hoc* disinfectants, provided such disinfectants are sold in a form approved and with instructions for use approved by some competent authority." Sir Auckland Geddes further urged on behalf of the deputation that this competent authority preferably should be the Ministry of Health, otherwise the Medical Research Council or a commission of experts. In reply, Mr. Neville Chamberlain promised to consider carefully the suggestions which had been made, and to communicate the result of his further consideration as soon as possible.

WE regret to announce the death of Dr. John Cleland, F.R.S., Emeritus Professor of Anatomy in the University of Glasgow, in his ninetieth year. We hope to publish a memoir in an early issue.

<sup>1</sup> *Methods and Problems of Medical Education*. Second series. The Sanitary Survey as an Instrument of Instruction in Medical Schools. New York, 1924.

## Nova et Vetera.

FRANCIS GALTON.

More than sixty years ago a professor in University College, London, David Masson, published the first volume of his *Life of Milton*. Bagehot said that it was very laborious, very learned, and in the main very accurate, but "composed upon a principle that is utterly erroneous." He remarked that: "For ancient heroes the exhaustive method is possible. All that can be known of them is contained in a few short passages of Greek and Latin, and it is quite possible to say whatever can be said about every one of these: the result would not be unreasonably bulky, though it might be dull. But in the case of men who have lived in the thick of the crowded modern world, no such course is admissible; over-much may be said, and we must choose what we will say."

Another professor in University College has just published the second volume of another biography<sup>1</sup>, when completed it may run to as many words as Masson's *Life of Milton*. To many people the events of John Milton's life would seem more interesting, certainly more romantic, than anything Francis Galton experienced; Masson had better "copy" than Professor Pearson. Nobody, however, save perhaps some diligent American compiler of a degree thesis, is likely to read in our time Masson's vast book, but we prophesy that Pearson's *Life of Galton* will be ranked by our descendants not very far behind Boswell's "Johnson" and Trevelyan's "Macaulay."

One reason of the superiority is on the surface: Professor Pearson is a much better literary craftsman than Professor Masson, commanding a style always cogent, and sometimes attaining a high level of eloquence. A profounder difference is that Professor Pearson has been guided by a clear and (we believe) correct principle. His aim has been to write the history of a mind, and he has realized that the working of that mind can only be made intelligible if, beside a study of the actions and reactions of the individual human being and his environment, a clear and correct picture is given of biological factors mingling in his ancestry which predetermined the essence of the individual human spirit. This is why so much of the first volume was devoted to genealogy, and the reader of that volume, recalling the scrappy but tedious pages devoted to genealogy in most full-dress biographies, will agree that exact detail artistically presented is not tedious, but fascinating.

<sup>1</sup> *The Life, Letters, and Labours of Francis Galton*. By Karl Pearson. Volume II. *Researches of Middle Life*. Cambridge: The University Press. 1924. (72 x 112, pp. xi + 424; illustrated. 45s. net.)

FRANCIS GALTON.

(Reproduced by permission of the proprietors of *Biometrika*.)

The present volume covers the most productive years of Galton's life: a good deal remains to be recorded because Galton's work ended only with his life, and one important part of his statistical work has been reserved for the concluding volume; but this volume leaves him a septuagenarian, and its reader will know fully what manner of man he was. We propose to refer, very briefly, to the detailed contents of the work; but, before doing so, we desire to record some general impressions.

An enumeration of the subjects upon which Galton wrote might well induce the reader to apply to Galton the adjective "versatile." In the sense of having a flexible intelligence, power of inventing or acquiring a new intellectual technique, Galton was indeed versatile. But, in common English usage, the adjective conveys a faint

flavour of depreciation, a suggestion of fickleness, of the comment on Renben, "unstable as water, thou shalt not excel." In this sense there was no versatility in Galton's career; he was from first to last, in the widest sense of the word, an anthropologist, a single-minded student of man. His intellect was, from one point of view, simple. We should surmise that he took very little pleasure in subtle dialectic, that he would have formed as low an opinion of Galen as Sydenham formed. He instinctively approached every problem from the experimental side. No man ever less needed Hunter's admonition to Jenner. Nobody ever had to say to Galton, "Why think, why not try the experiment?" He was always trying the experiment. One may choose three quite typical examples from different periods of his life.

In 1860, still actively interested in the problems of travel, he writes: "Unthinking persons talk of the fearful rapidity of a lion's or a tiger's spring. It is not rapid at all; it is a slow movement, as must be evident from the following consideration.

No wild animal can leap ten yards, and they all make a high trajectory in their leaps. Now think of the speed of a ball thrown, or rather pitched, with just sufficient force to be caught by a person ten yards off; it is a mere nothing. The catcher can play with it as he likes; he has even time to turn after it, if thrown wide. But the speed of a springing animal is undeniably the same as that of a ball, thrown so as to make a flight of equal length and height in the air. The corollary to all this is that if charged, you must keep cool and watchful, and your chance of escape is far greater than non-sportsmen would imagine." In other words, before waxing rhetorical over the death-dealing leap of a lion, check your eloquence with a tennis ball.

Twelve years later Galton is writing a paper on the efficacy of prayer. If prayer is objectively efficacious, surely we ought to be able to find some evidence of it. Why not find out whether people who pray or are prayed for a good deal live longer than those to the affairs of whom the

# FRANCIS GALTON.

MARCH 14, 1925]

Almighty's attention is rarely called? Galton promptly goes to a biographical dictionary and works out the mean age at death of eminent clergy, lawyers, and medical men, and finds that for clergy it is 66.42 years, for lawyers 66.51 years, and for doctors 67.07. He also discovers that the nobility are peculiarly subject to insanity, although we regularly pray that they may be endued "with grace, wisdom, and understanding." One need not be told how much offence so uncompromising a believer in the experimental method gave fifty years ago.

In his old age Galton was greatly interested in the experimental testing of the theoretical laws of frequency, and worked much with dice. Such practices are discountenanced in the best intellectual circles, and Mr. Maynard Keynes has spoken with freezing contempt of those who "satisfy a certain idle curiosity," in this way. But experiments on "chance" have guided men of fair ability—Buffon, Laplace, Galton, Weldon, and Pearson—to some interesting results. These examples are trivial, but they are characteristic. Galton's genius was, we think, experimental.

The first chapter in this volume is concerned with transition studies; the most important was, perhaps, meteorology, to which Galton was led by a realization of the value of a knowledge of climate to the traveller and explorer. When Galton resigned from the Meteorological Council in 1861, Sir Richard Strachey wrote: "It is no exaggeration to say that almost every room in the office and all its records give unmistakable evidence of the active share that you have always taken in the direction of the operations of the Office." Many examples of Galton's sagacious ingenuity in devising apparatus are given, and a paper on "Barometric Predictions of Weather," published in 1870, is of special interest in his life story, because it is a first approximation to the principle of statistical correlation, his greatest contribution to the general methodology of science.

In the next chapter Professor Pearson gives an analysis and discerning criticism of Galton's first very important book, *Hereditary Genius*. It would be hard to better this judgement: "*Hereditary Genius* is one of the great books of the world, not so much by what it proves, as by what it suggests. Detailed proof was to come afterwards, step by step. Its publication formed the central epoch of Galton's life, and nearly all his later work may be seen therein to take its origin."

In the next chapter, which includes an interesting correspondence with his cousin Charles Darwin, we see Galton at work as an experimental biologist. There was a divergence of view between Darwin and Galton on the subject of "pangenesis"; subsequent results have shown that Galton saw more of the truth than Darwin. A generation before the rediscovery of Mendel's work Galton fully realized that somatic characters were no measures of gametic possibilities, and that the second generation of hybrids showed more diversity than the first.

At the end of the seventies Galton's anthropological quest led him to psychometry, and he became the first English experimental psychologist. He did not actually found an English school; in modern times our students have rarely believed anything new (to them) to be important until it has been worked on in Germany. But, in fact, Galton was the English pioneer, and perhaps *Inquiries into Human Faculty*, published in 1869, contains more matter familiar, at second or third hand, to most people than any of his other books. In his remarks upon the permanent effects of childish experiences and the "antechamber of consciousness"—"The thronging of the antechamber of I am convinced, altogether beyond my control; if the ideas do not appear, I cannot create them, nor compel them to come"—are distinct anticipations of a trend of psychological thought and research which Freud and his pupils have made familiar to this generation. One cannot but regret that Galton's statistical method, whether as an instrument of research or critical appraisal, has had so far, little share in the development of psycho-analysis. That workers in experimental psychology in general display more statistical competence than experimental physiologists—concerned, as the latter often are, with problems

equally needing statistical evaluation—is due to Galton's work.

The next chapter describes Galton's photographic work. Composite portraits are associated by everyone with Galton's name, and Professor Pearson has provided a full account, beautifully illustrated, of what Galton did in this field. But composite portraiture was only an item in Galton's researches; his studies of methods of photographic measurement are perhaps of greater importance—he was still working on these in the last year of his life. "In heredity and statistics," writes Professor Pearson, "the younger generation has been found to take up his work; in photography and portraiture his pioneer steps have not yet been trodden into a well-marked track by enthusiastic disciples."

The last chapter is devoted to Galton's statistical work other than his researches based on use of the new organon, the calculus of correlation, which is to be examined in the next volume. Professor Pearson was justified in adopting this course because it enables him to trace the development of Galton's ideas and to show how important were the results reached even before Galton arrived at his crowning achievement. A full account of the Anthropometric Laboratory of 1884 is given and of Galton's attempts to secure a more rational system of assigning marks in examinations. Upon the latter point Professor Pearson has an interesting footnote, in the course of which he mentions that, having examined the marking statistics of the London Matriculation Examination, "He was startled to find that the relative personal equation of examiners in history, languages, and literature was very greatly larger than the relative personal equation of examiners in branches of science; and that no systematic method of correcting for this personal equation had been adopted. Thus a candidate's chance of passing depended largely on the examiner to whom his paper was allotted! Galton was particularly anxious that marks for physical efficiency should be awarded in competitive examinations, 'in order to pass those candidates who being a little under par intellectually are far above par bodily; conversely to weed out those other candidates who, not being particularly fit in respect to their brains, are at the same time of decidedly inferior physique.'"

At the end of the chapter is a series of letters exchanged by Francis Galton and Florence Nightingale on a proposal of the latter to attempt to secure the endowment of a chair of Applied Statistics. In this correspondence Florence Nightingale seemed to have even larger ideas than Galton, and her arguments may perhaps have influenced his own endowment of twenty years later.

It is not possible even to enumerate the topics discussed in the chapter, but the gradual improvement of technique, illustrating how Galton never abandoned a simple numerical method until he had got all there was to be got from its exploitation, is characteristic of the man.

As we said at the beginning, the reader of this volume will have gained a clear mental picture of the man, such a man as the poet may have known:

"He stood and watched the cobbler at his trade,  
The man who slices lemons into drink,  
The coffee-roaster's brazier and the boys  
That volunteer to help him turn its wheel.  
He glanced o'er books on stalls with half an eye,  
And fly-leaf ballads on the vendor's string,  
And broad-edge bold print posters by the wall.  
He took such cognizance of men and things,  
If any beat a horse, you felt he saw;  
If any cursed a woman, he took note;  
Yet stared at nobody,—you stared at him.  
And found, less to your pleasure than surprise,  
He seemed to know you and expect as much.  
So, next time that a neighbour's tongue was loosed,  
It marked the shameful and notorious fact,  
We had among us, not so much a spy,  
As a recording chief-inquisitor.  
The town's true master if the town but knew!"

Substitute for "master" in the last line "teacher" and this is a fitting characterization of Francis Galton. If the town but knew, it would become a wiser, saner town.

## England and Wales.

### WELSH NATIONAL MEDICAL SCHOOL.

The long controversy over the future status of the Welsh National Medical School, to which we have referred on several previous occasions, has now been advanced a stage further towards settlement. At the last meeting of the council of the University of Wales a communication was read to the effect that the Privy Council had decided against the proposal that the Welsh Medical School should continue to be an integral part of the South Wales and Monmouthshire University College, Cardiff, and in favour of the principle that the Medical School should be a separate entity as a National School of Medicine of the University of Wales. The Privy Council took the view that for the medical school to become a national institution in the sense in which it is desired that it should be, the school ought to be a separate national unit with its own controlling authority, subject only to the broader lines of development laid down by the University of Wales as a whole. It is pointed out by the Privy Council that the school must act for the whole of Wales, and not only be a faculty of the college at Cardiff, if it is to fulfil its great purpose as a national institution. The Privy Council has been engaged for several months in examining the arguments presented by both sides in the controversy, and has reached its decision after taking the fullest possible advice. The arguments against nationalization were admitted to have considerable weight; it had been urged that the separation of one class of students from another was an educational error, and, also, that a decision adverse to the claims of Cardiff might possibly lead to rupture of the federal system of the University of Wales. The financial aspect of the whole question was also considered very carefully. The communication from the Privy Council, whilst ending the matter so far as the Council is concerned, has no final and binding value, since before it can become effective it must receive the acquiescence of the College Council, the Board of Medicine, the University, and the co-operation of the local authorities. The process of financial disentanglement of the Medical School and the College at Cardiff may not be easy, and some of the problems with reference to the allocation of buildings and funds may, possibly, entail some—it is hoped friendly—litigation. The hope is expressed, however, by the Privy Council that the decision will prove eventually to be acceptable to all parties in the controversy.

### QUEEN'S HOSPITAL, BIRMINGHAM.

The Queen's Hospital, Birmingham, was opened in 1841, with seventy beds. For many years past its work has been subject to great difficulties owing to the limitation of the buildings. In 1908 a new medical block was erected, but the surgical work is at present being conducted in the original building, which is entirely inadequate for modern treatment. A scheme of extension has therefore been planned, at an estimated cost of about £120,000. It is proposed to build behind the older portion of the hospital a new block to contain six new surgical wards, three large operating theatres with anaesthetic rooms and sterilizing rooms, and a small special x-ray department, the whole forming one complete unit. A large and commodious general x-ray department is also to be established. The addition of this new block will increase the capacity of the hospital by over a hundred beds. The out-patient department is to be completely remodelled, new open-air wards will be erected, and new departments arranged for diseases of women, ear, nose, and throat diseases, and for electrical and mechanical therapeutics. The pathological department is to be enlarged and remodelled, and adequate accommodation provided for resident surgeons, nurses, and domestic staff. It will not be necessary to purchase any additional land, and no interference with the present hospital work will be caused by the building operations. It is calculated that this extension scheme will enable an additional 1,750 patients to receive expert surgical treatment each year. In our correspondence columns this week we publish a letter from Dr. Kirkby Thomas of

Birmingham, treasurer of the Queen's Hospital Past and Present Residents' Association, drawing attention to the old students and residents fund, which has been opened for the endowment of a bed in the hospital.

### BIRMINGHAM CHILDREN'S HOSPITAL.

Since the beginning of this year a "sunlight clinic" has been established at the Birmingham Children's Hospital as an extension of the x-ray department, an arc lamp having been presented by the late Mr. Albert Keen. Considerable benefits have resulted in the treatment of rickets; the children attend three times a week for a period lasting three months. Gradually increasing exposures to ultra-violet rays are controlled by x-ray photographs taken at regular intervals. It is hoped that similar good results will be obtained in the case of marasmic children. The extra rooms needed for the extension of this clinic will be available when the new out-patients' department is opened shortly. It is calculated that £1,000 will equip and maintain the clinic for twelve months, and in that period provide adequate treatment for over 1,200 children.

### KIDDERMINSTER INFIRMARY.

On April 5th, 1924 (p. 642), we referred to the proposed extension of the Kidderminster Infirmary and Children's Hospital. The cost of this extension was estimated at £25,000, and at the annual meeting of the governors of the infirmary on February 24th the president, Dr. J. J. Stretton, was able to announce that £20,700 had already been promised. Besides this a sum of over £4,500 had been promised for endowment and upkeep. Dr. Stretton pointed out that the estimated annual increase of expenditure after the completion of the extension would be approximately £1,000, or less than one-seventh of the expenditure of the past year, whereas, comparing the new building of 1872 with the old one of 1870, the change had more than doubled the then annual expenditure. He hoped, therefore, that there would be little difficulty in obtaining the increased support now required. The income for the previous year amounted to £7,582, and the expenditure to £7,754; an additional sum of £1,511 had been received for investment. The number of in-patients treated during the year was 1,048, and there were over 17,000 attendances of out-patients. The Saturday Fund Committee had raised a sum of £3,173, an increase of £343 over the previous year. A strong appeal was made to individual workers, whether employed in factories or elsewhere, as also to domestic servants, to agree to a voluntary levy of 2d. per week. Although there were a large number of these contributors, yet the workers in several firms had not yet associated themselves with the scheme. A contract has now been accepted for building a new children's ward, out-patient department, and laundry, and various alterations and improvements of the present building will be begun very shortly. In accordance with the new rules, which come into operation at the end of March, the infirmary will in future be known as the Kidderminster and District General Hospital.

## Scotland.

### PROFESSOR OF CLINICAL SURGERY AT EDINBURGH.

As briefly announced last week the King has, on the recommendation of the Secretary for Scotland, appointed Mr. John Fraser, M.D., Ch.M., F.R.C.S.Ed., to be Regius Professor of Clinical Surgery in the University of Edinburgh, in the room of Sir Harold J. Stiles, whose resignation takes effect on March 21st. Dr. Fraser, who graduated M.B. with honours in 1907, is a native of Tain. He became a Fellow of the Royal College of Surgeons of Edinburgh in 1910, and took the degree of M.D. in 1912, being awarded a gold medal for his thesis, and the degree of Ch.M. with honours in 1910. He has been assistant surgeon to the Edinburgh Royal Hospital for Sick Children since 1920. During the war he served with distinction in the Royal Army Medical Corps and gained the Military Cross. He is the author of an important work on *Tuberc-*

*culosis of the Bones and Joints in Children*, published in 1914, and of numerous papers on surgical shock, tumours of the kidney, abdominal emergencies in children, and pneumococcal peritonitis. He has gained a high reputation in the medical profession as a skilled and successful operator, as well as for valuable research on surgical subjects.

#### LARBERT INSTITUTION ANNUAL REPORT.

The sixty-fourth annual general meeting of the Royal Scottish National Institution, Larbert, was held in the Christian Institute, Glasgow, on February 24th, Mr. William Wilson presiding. Dr. Clarkson, superintendent of the institution, submitted the annual report, in which he said that the lives laid down by the founders had been followed consistently for sixty-four years. The aim was, not to treat mental disease, but to care for children who were crippled in mind. The main business, therefore, was to help these children to realize what personality they possessed. Too many people believed there was something foreign and disagreeable in such children, but each of them was a human being with his own way of looking at things and his little mind working logically in its own manner. During the past year over £200 worth of goods made by the children had been sold. These children remained children all their lives, for it had now come to be recognized that mental defect was not curable. The directors had been attempting to acquire land near the institution for the purpose of establishing a colony where children who, if they returned home, would only be a burden to their relatives, might be cared for during their lifetime. The average number of children maintained within the institution during the past year had been 506.6. The chairman, in moving the adoption of the report, said that a large sum of money had been spent during the past three years in the reconstruction of the buildings; £3,000 remained to be found, but it was expected that the institution would be quite free of debt within a short time. The Marchioness of Ailsa submitted a resolution expressing satisfaction at the increase of interest which was now taken in the more adequate care of mentally defective persons, and commending the institution to the generous support of the public. She said that the necessity was now recognized of taking life-care of the mentally defective in colonies, so that they could continue to render service within the limits of their capacity, although unable to take their places in the outside world in competition with ordinary persons. Reference was also made to the efforts now being made by the Women Citizens' Association to raise funds for the establishment of a colony for mental defectives.

#### EDINBURGH FOOT CLINIC.

The first annual meeting of the Edinburgh Foot Clinic was held in the City Chambers on March 4th. The chairman, Viscount Novar, in opening the meeting said that the clinic aimed at treating one of the minor and more unromantic afflictions from which people suffered. It should be remembered, however, that the larger proportion of pain from which people suffered came from the teeth and toes rather than from the more important organs, to the curing of which the heroic efforts of medical science were directed. If those suffered who had the best of boots and who could secure the best attention, many who had to put up with what they could get in these matters suffered from a deplorable condition of the feet. This foot clinic was the first dispensary of the kind in Scotland and attached to it was a school of chiropody. In the report submitted by Mr. J. Fleming Robertson, C.A., honorary secretary and treasurer, it was stated that 1,368 patients had attended the clinic, and that the total number of treatments was 3,132, and there was a waiting list of appointments for treatment to the number of 1,311. The clinic was open two nights in the week, and in the school of chiropody connected with it twelve students were at present attending classes. The total ordinary revenue from subscriptions, patients' fees, etc., amounted to £284 2s. 2d., while the expenditure was £324 16s. 10d.

The capital required to place the clinic on a proper financial basis amounted to £150, while the sum required for ordinary purposes during the current year was estimated at £200.

#### TECHNICAL CRITICISM OF STEEL HOUSES.

The technical committee appointed by the National Housing and Town Planning Council to consider the housing question has issued a report criticizing the steel houses which are made by several firms in Glasgow, and of which a description was given in the *BRITISH MEDICAL JOURNAL* of October 18th, 1924. It is claimed that houses constructed of wooden frames covered with steel plates painted once on the inside when first fixed, and thereafter painted on the outside at frequent intervals, will last for forty years. The committee doubts whether this expectation will be fulfilled, as it thinks that rusting will be set up at the joints and spread to the inside when it is impossible to paint both surfaces and so protect them against oxidation. It criticizes also the use of wood pulp linings for the internal facings of the walls, because of the considerable risk that walls thus constructed may become verminous. It holds that solid partitions are more satisfactory than hollow walls, which harbour vermin and frequently become dilapidated when made of lath and plaster. The Weir type of house, it is thought, will be more readily affected by rapid changes in the temperature than would be houses of thicker or solid walls, because where the walls are not finished with absorptive substances like lime or its derivatives absorption of moisture by articles in the room will be noticeable, and thus mildew may be set up in clothing hung in wardrobes, wire mattresses and other metal articles may rust, and bed linen become damp. The committee has not much criticism to offer with regard to the relative cost between steel-sheeted houses and brick houses except that the latter can be produced, it considered, at a cost of a few pounds less than the former. The use of granular concrete poured between sheets or placed *in situ* is thought to be worthy of experiment, as is also the use of timber in country districts. A large measure of approval was given to methods of steel frame construction by which the roof is placed in position before the walls are built, thus enabling all trades to work continuously without stoppage as a result of bad weather. The committee, however, recognizes that there is a shortage in building materials of brick, stone, tiles, and slates, and recommends that inquiry should be made both by the Government and local authorities to stimulate increased supplies of these materials, especially of tiles and slates. It recommends the establishment of a departmental committee to consider the steps which should be taken to secure proper regional distribution of the houses to be built under the national housing policy.

#### MONTROSE INFIRMARY IMPROVEMENTS.

At a meeting of subscribers of Montrose Royal Infirmary plans were approved for the provision of a new operating theatre and an extension to provide an additional ward with ten beds at an estimated cost of £2,000. The hospital now contains fifty beds, including seven for the treatment of private patients. It was resolved to use a gift of £500 from Sir James H. Warraek, K.B.E., Edinburgh, for the erection of the new theatre, and to pay for the other buildings out of legacies.

#### LEITH HOSPITAL ANNUAL REPORT.

The annual report of the Leith Hospital stated that the new cases treated in the wards and the out-patient department together numbered 14,868 during the past year. The ordinary income had been £12,274 and the ordinary expenditure £14,272, while the extraordinary income totalled £11,121 and the extraordinary expenditure £56. The chairman, in moving the adoption of the report, referred to the satisfactory position of the hospital, but pointed out that when the new wing, which it was hoped would be completed by the end of June, was opened and fully equipped the annual expenditure would become much heavier.

## Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

SUPPLEMENTARY Estimates, unemployment, rent restrictions, and the policy of the Air Ministry have been the chief topics in the House of Commons this week. The House of Lords has read the Therapeutic Substances Bill a second time, and Lord Banbury has reintroduced the Dogs Protection Bill. During the debate in the Commons on unemployment it was intimated that the Government felt it had to deal by some new method with the men who were unemployed at the age of 60 or 65. The method would probably be by insurance, though not under the Unemployment Insurance Act.

Dr. Fremantle has obtained first place on the evening of March 24th, and will move a resolution on housing. He proposes to deal specially with town planning and garden cities. A statement on the Government's housing policy may, however, be made next week. The Rent and Mortgage Interest (Restrictions Continuation) Bill was brought in by Mr. Neville Chamberlain on March 6th, and its second reading commenced on March 11th. It proposes to extend the present system of rent control for two years and a half, with rent tribunals to deal with harsh cases for five years thereafter.

### The Warning Notice of the General Medical Council.

On March 5th Mr. A. Greenwood, formerly Parliamentary Secretary of the Ministry of Health, asked the Prime Minister whether his attention had been called to the Warning Notice issued to registered medical practitioners by the General Medical Council, purporting to give a summary of the resolutions and decisions of the Council upon forms of professional misconduct; whether he was aware that in consequence of the issue and circulation of that notice registered medical practitioners were deterred from assisting, by administration of anaesthetics or otherwise, qualified but not registered practitioners of osteopathy, bone-setting, and other new forms of treatment of human ailments; whether he was aware of the feeling of dissatisfaction among the general public, and also among many medical practitioners, with the exercise by the General Medical Council of its functions and powers conferred by the statute of 1858; and whether he was prepared to set up a commission or departmental committee of inquiry into the operation and administration of the various Medical Acts, and the exercise by the General Medical Council of its functions and powers under such Acts, with a view to the introduction of such legislation as might be necessary to ensure the recognition and legal regulation in this country of osteopathy, bone-setting, and other new methods of treatment, and to safeguard both qualified practitioners and the general public. Mr. Austen Chamberlain, replying for the Prime Minister, said he understood that the Warning Notice to which reference was made was adopted virtually in its present form by the General Medical Council in 1897. Subsequent alterations had been merely verbal. He was aware that by the issue of that notice medical practitioners were deterred from assisting unregistered osteopaths and others. While the application of the principles laid down in the notice to particular cases might have given rise to criticism, there was no evidence of any general dissatisfaction among the public or the medical profession, and he saw no necessity for the appointment of any commission or committee such as was suggested. Mr. Greenwood asked whether the Government would receive a deputation of members of Parliament interested in the subject. Mr. Austen Chamberlain suggested that that proposal should be made to the Minister of Health.

### Bill to Amend Law as to Coroners.

The Home Secretary, Sir William Joynson-Hicks, has stated, in answer to Mr. Dixey, that he hopes to introduce a bill very shortly to amend the law relating to coroners' inquests.

### Boric Acid in Food.

Mr. Hardie, on March 9th, asked the Minister of Health a question with regard to a paragraph in the final report on Preservatives and Colouring Matters in Food (paragraph 59), in which it was stated that it was evident that individuals might consume quite considerable quantities of preservatives in the course of an ordinary day's diet, and that it was easy to imagine a reasonable meal which might contain 20 or even more

grains of boric acid besides other preservatives; and whether, in the opinion of the Minister's official adviser, the effects of 20 grains of boric acid were good or bad for the average individual consumer. Sir Kingsley Wood answered that the Minister was aware of the statement referred to. He was advised that the continued consumption of such quantities of boric acid would be likely to have a deleterious effect. Sir Kingsley Wood added that regulations were being drafted to put an end to the use of boric acid in mixtures with sulphuric fumes or otherwise without the knowledge of the Ministry, and to prevent the dusting of food in shops with supposed preservatives.

### Insulin.

The Public Health (Scotland) Amendment Bill to empower public health authorities in Scotland to provide insulin for sufferers from diabetes, the discussion of which was interrupted as reported last week, was read a second time on March 4th by 272 votes to 115. Mr. W. Adamson, who, when Secretary for Scotland in the last Government, had introduced a similar bill, said that the provision of insulin then involved a weekly expenditure of 4s. or 5s. for each person. Though the price had fallen, its purchase still taxed the resources of certain sections of the people. Under the existing law insulin could be provided free in Scotland to persons insured under the National Insurance Acts, and to those for whom the Poor Law authorities were responsible. Further, expectant mothers, nursing mothers, and children under 5 years of age could be supplied with insulin free, through maternity and welfare schemes; no provision was, however, made for the rest of the community. He objected to the restriction of the bill to insulin, and said that its title would prevent an amendment being moved in Committee to enable drugs to be made available by an order of the Scottish Board of Health in the event of any equally effective remedy being found for some other disease. Promptness was necessary. Dr. Drummond Shiels also objected to the restriction of the bill to insulin. The Government had been influenced by the objection of local authorities, which were made on purely financial grounds. Most members of the House had received a memorandum from the Scottish Branch of the Pharmaceutical Society of Great Britain with regard to the method of supply by local authorities; possibly other drugs might be discovered for which some provision such as the Pharmaceutical Society suggested should be made. Dr. Walter Elliot, Parliamentary Under Secretary of Health for Scotland, said that the local authorities were willing to bear the whole of the small expense the bill involved. He contended that if the scope of the bill were extended it should be by specific legislation. As to the contrast between England and Scotland, the English Public Health Act (1875) only provided for the temporary supply of medicines. Mr. Ramsay MacDonald said that the powers enjoyed by local authorities to be taken away, but to give real power to local authorities to as they arose. He would prefer a more summary procedure than that by Order in Council, which had been proposed in last year's bill. Sir Alexander Sprot, Mr. Martin, and Mr. Campbell Stephen also spoke. The bill was referred to the Standing Committee on Scottish Bills.

### Ministry of Pensions.

Sir Richard Luce, on March 5th, asked the Minister of Pensions what steps were being taken to make permanent medical appointments under the Ministry; and if British nationality and active service in the late war would be taken into special consideration in making selections. Colonel Stanley, Parliamentary Secretary, said that it had been decided to make appointments on the staff of the Ministry and to fill them from the existing full-time temporary medical staff. All members of that staff within the prescribed age limit of eligibility had been notified of the conditions of the appointments, and a selection committee, presided over by the First Civil Service Commissioner, was interviewing a selected number of the candidates. All candidates must satisfy the general rule of the Civil Service as regards British nationality and must have served in the forces in the late war. Mr. Watts asked whether Colonel Stanley was aware that disabled medical men, with several years' war service, who had served the Board for years, were being displaced by young men in many cases engaged in general practice and with no war experience. Colonel Stanley said that point did not arise on Sir Richard Luce's question, which concerned established appointments.

Answering Sir Philip Richardson, on March 10th, the Minister of Pensions said the Central Advisory Committee on Pensions, appointed under the Act of 1921, held two meetings in 1922, three in 1923, none in 1924, and one this year (February 17th). The Ministry's policy had been to lay before the Committee for its advice all proposals of importance or difficulty, and improvements had been made in accordance with its advice, though it was not the practice for the Committee to pass formal resolutions.

The Ministry of Pensions aims to arrange that where a man whose disability does not prevent him from working is undergoing treatment, the treatment shall, so far as possible, be given at evening clinics.

The Ministry of Pensions is asked to consider the suggestion that local Pensions Committees should be authorized to pay the railway fare of anyone who is to assist an appellant suffering from neurasthenia or mental disease to state his case before the Appeal Tribunal.

## BILLS.

*Dogs Protection Bill.*

Lord Banbury introduced the Dogs Protection Bill in the House of Lords on March 5th, explaining that it was to prevent the vivisection of dogs. The measure was read a first time. No date had been fixed for the second reading debate at the time of going to press.

*Therapeutic Substances Bill.*

The Therapeutic Substances Bill, to provide for the regulation of the manufacture, sale, and importation of vaccines, serums, and other therapeutic substances, was presented in the House of Lords by the Lord Privy Seal (Lord Salisbury) on March 3rd, and was read a first time. A bill with the same title passed through all stages in the House of Lords last year, and reached the House of Commons in June; nothing more was heard of it.

In moving the second reading of the bill, on March 10th, the Marquess of Salisbury said this was a bill which the Lords had passed last session. Its purpose was to prevent the users of therapeutic substances being misled, and it dealt with substances where special provision for standardizing was necessary, because on the standard and strength depended the health of the users. The medical profession could not know what it was prescribing unless it could rely on a standard, and in some cases great mischief could arise from uncertainty, some of the substances being highly poisonous. The bill dealt with serums, vaccines, and special preparations such as salvarsan. It was impossible to decide the amount of arsenic in salvarsan save by biological tests, while pituitary extract, if untested, might vary in the strength of the active principle by as much as the proportion of 1 to 8. The bill proposed licences for all persons preparing such therapeutic substances, and for the places where they were prepared. The conditions would be included in the regulations, which would be laid on the table of the House. The Minister of Health, the Secretary for Scotland, and the Ministry of Home Affairs in Northern Ireland, or their representatives, were to be a committee to draft these regulations. There would also be an advisory committee, including representatives of the three departments, of the research councils, and of other bodies, including the Pharmaceutical Society. There was power to add, by Ministerial order, substances to the schedule of the bill. Imported therapeutic substances were to be tested, with the exception of substances imported for research under licences. The question with which the bill dealt had been before the appropriate body in the League of Nations, which had moved the various Governments to establish standards of therapeutic substances. Many countries had already done this. If we had not our export trade in these substances would suffer.

Viscount Haldane drew attention to Section 3, Subsection 2, of the bill, authorizing special licences for research. He said the schedule contained many things which men of science might need at short notice, and it was not their practice to apply for licences. He feared this subsection might deter useful research, and urged the Government to facilitate the importation of small quantities for research. This view had been put to him by distinguished men engaged in research.

Lord Salisbury said the point put forward by Lord Haldane would be considered in Committee.

The bill was read a second time.

*A Consolidating Health Bill.*

The text of the Public Health Bill introduced by Mr. Womersley and supported by Mr. George Thorne, Mr. Clynes, Sir Charles Wilson, and others, is now available. It consists for the most part of a collection of clauses which have been commonly allowed in local Acts passed since 1907, brought into more suitable form for general legislation. Compulsory adoption is proposed for the clause providing a penalty for unnecessary contact with the body of a person dying of infectious disease, for the clauses dealing with the medical inspection of inmates of common lodging-houses, and for the closing of such lodging-houses on account of infectious disease within, and for amendments of the law relating to baths and washhouses. The bill applies in general to England and Wales, exclusive of London. Only the provisions relating to baths and washhouses are to apply to London. Permissive powers are proposed as to the provision of drinking fountains, the paving and drainage of courts, reconstruction of drains, abatement of nuisances caused by occupation of tents and vans, the cleansing of verminous articles, houses, and persons, power to establish cold stores, and prohibition of the sale of food by rag and bone dealers. The second reading of this bill is put down for March 20th.

*Imperial Institute Bill.*

The Imperial Institute Bill was read a second time without debate on March 4th. Under the scheme of reorganization to which the bill is to give effect the Imperial Institute and the Imperial Mineral Resources Bureau will be amalgamated. The bill provides for a parliamentary grant of £9,000 annually for five years after its passing.

*Guardianship of Infants Bill.*

The Guardianship of Infants Bill, read a second time on March 4th without a division, and sent to Standing Committee A, provides for equality between the father and mother in any case

that may come before the courts under the existing law touching the custody or upbringing of the infant, and enjoins the court to regard the welfare of the infant as the first and paramount consideration.

*Milk and Dairies Acts.*—Answering Mr. Barnes, on March 5th, Sir Kingsley Wood, Parliamentary Secretary of the Ministry of Health, said that it was not proposed to ask Parliament to postpone further the operation of the Milk and Dairies (Consolidation) Act, 1915, which would come into operation on September 1st. The Milk and Dairies (Amendment) Act, 1922, would continue in force. Sir John Gilmour, Secretary for Scotland, announced that the Milk and Dairies (Scotland) Act, 1914, would also come into operation on September 1st.

*Medical Women's Pay.*—Miss Wilkinson, on March 5th, asked the Chancellor of the Exchequer whether he was aware that the Government was the only authority making a difference between the pay of medical men and women, and whether he would consider the matter. Mr. Churchill replied that the matter had been considered by the Labour Government, and he had not found it possible to decide to reverse their decision. Any request for an opportunity to discuss the matter should be addressed to the Prime Minister.

*Imported Drugs.*—Mr. Crawford, on March 10th, asked the President of the Board of Trade if phenacetin, phenagene, and many other chemicals scheduled as liable to duty in Part I of the Safeguarding of Industries Act, 1921, were still not manufactured in this country; and if he would at once order the removal of such articles from the dutiable list to lessen the cost to hospitals and similar institutions where they were so largely used. Sir Philip Cunliffe-Lister replied that "phenagene" did not appear in the list of goods dutiable under Part I of the Safeguarding of Industries Act. As regards phenacetin, its manufacture in this country was at present suspended. The number of such listed products produced in the United Kingdom was steadily increasing, and he was not prepared to introduce legislation to remove articles from the dutiable list. In reply to another question it was stated that of some 2,000 fine chemicals listed in Part I of the Safeguarding of Industries Act the manufacture of 1,000 had been undertaken by a British firm since the passage of the Act.

*Influenza Research.*—Sir Alfred Butt asked the Minister of Health whether his department was initiating or assisting any research for the purpose of discovering an antitoxin for influenza which could be generally employed. Sir Kingsley Wood, Parliamentary Secretary of the Ministry, replied that research was being vigorously prosecuted under the auspices of the Medical Research Council as well as by pathologists in the Ministry of Health, but present knowledge gave no immediate prospect of a discovery of an antitoxin suitable for general use in cases of influenza.

*Mental Hospitals.*—At the close of the sitting on March 10th Mr. Taylor called attention to the conditions in mental hospitals, and moved that reform of these conditions was of urgent importance. Mr. R. Richardson, in seconding, asserted that there were thousands in these hospitals who should not be there. Sir Kingsley Wood, replying for the Ministry of Health, said the Government must await the report of the Royal Commission on the Lunacy Laws now sitting before expressing an opinion on the general questions raised. He expected the Commission to report next year, and promised prompt consideration. In regard to the conditions of employees in mental hospitals, the Board of Control was anxious that many of the reforms recommended should be adopted by local authorities. It had no power to enforce such recommendations, but would bring them before the local authorities. The Ministry of Health thought that the conditions of employment needed improvement and would see whether the grant could not be increased. He offered to confer with the mover of the motion to see what could be done in the areas where the need was most pressing. The motion was then withdrawn.

*Miner's Silicosis.*—Mr. Geoffrey Peto, on March 10th, asked the Secretary for Mines for how long the question of silicosis among coal-miners had been under investigation by the Health Advisory Committee; and when it was likely to reach a decision as to its scheduling under the Workmen's Compensation Act. Colonel Lanc-fox replied that the question had been under consideration for two years. The evidence received so far was insufficient to justify scheduling, and the Committee would welcome further evidence.

*Opium in India.*—On March 9th Mr. Buchanan asked Earl Winterton, Under Secretary of State for India, whether the Government of India was aware that the use in India of opium was supported by British officials as a well established and, on the whole, not an injurious habit; and what steps he proposed to ensure that the use of this drug should be discontinued. Earl Winterton replied that in the opinion of the Government of India, based on the findings of the Royal Commission which in 1895 investigated the consumption of opium in India, was that centuries of inherited experience had taught the people of India discretion in the use of opium, which for the most part was without injurious consequences. The distribution of opium was strictly controlled in accordance with the provisions of the Hague Convention, 1912, and the Secretary of State for India did not propose to interfere with the discretion of the Government of India and of the Indian Provincial Governments in the exercise of that control.

*Illness Alleged to be Due to Vaccination.*—Mr. Cecil Wilson asked a question with regard to a man who had enlisted in December,

1917, in good health; he had not previously been vaccinated. He was vaccinated in January, 1918; his health had afterwards broken down and he suffered from extensive tuberculosis of the lung. This breakdown was attributed to the vaccination, and it was asked that the refusal to grant a pension might be reconsidered. Colonel Stanley replied that the man made no claim to pension until nearly five years after demobilization, when, after careful consideration of all the evidence, the Ministry of Pensions was unable to regard his condition as connected with service. He appealed to the Independent Appeal Tribunal and submitted full statements of his health during service and subsequently, but the Tribunal confirmed the Ministry's decision. The Ministry saw no ground for granting a pension.

*Spirits in Sickness.*—Lord Apsley, on March 5th, asked the Home Secretary to consider the relaxation of the regulations which prevent the public from purchasing, in cases of sickness, a bottle of wine or spirits before 10.30 a.m. or between 2.30 and 6 p.m. The Home Secretary said he had no power to alter the regulations, nor was he aware of any such inconvenience as would justify amendment of the law.

#### Notes in Brief.

The Minister of Health is aware that some complaints have been made of delay in payment of benefit to insured persons who fell sick, but it was not thought necessary to set up a departmental committee on the subject.

During the last twenty years forty persons who were on conviction less than 21 years of age have been sentenced to death in England and Wales, and fourteen have been hanged.

Permits to undertake work in this country were issued during 1924, under the Aliens Order, 1920, to seventeen nurses, mainly probationers, and were refused to eight.

A bill to provide for the registration of funeral undertakers and a bill for the regulation of movable dwellings were introduced into the House of Commons on March 5th—the first by Mr. Groves and the second by Major Wheeler.

The new Central Advisory Committee of the Ministry of Pensions met on February 17th.

Factory inspectors have been notified that any premises where multigraphing by means of machines set with types is carried on regularly and extensively are included in the Factory Acts.

The Ministry of Health is pressing for improvement in the sleeping accommodation for women vagrants at certain casual wards.

The Royal Commission on Local Government cannot yet indicate when its report will be presented.

The number of old age pensioners rose from 916,771 on March 31st, 1924, to 997,160 on December 31st.

The Minister of Labour is considering the report of an investigation into working conditions in the clinical thermometer industry.

Answering Mr. S. Mitchell, on March 5th, Colonel Ashley, Minister of Transport, said he was disposed to agree with the Departmental Committee on the Regulation of Road Vehicles that it was impracticable to compel all applicants who desired licences to drive motor vehicles to produce medical certificates of mental and physical fitness before the licence was granted.

During 1923 and 1924 the number of cattle slaughtered in connexion with outbreaks of foot-and-mouth disease was 111,933 and of sheep 54,532. The compensation paid totalled £3,326,942. The Ministry of Agriculture hopes in the near future to test the Shaw remedy for foot-and-mouth disease.

Three cases of rabies occurred in dogs in Great Britain during the last three years. All were imported dogs still in quarantine. The restrictions will not be relaxed.

The Home Secretary does not think the danger from toy pistols is sufficient to justify legislation extending to them the provisions of the Firearms Act.

It is not thought desirable to allow good conduct prisoners to smoke during exercise, but the privilege of dining together is being extended.

Under the Housing Acts (1923 and 1924) 51,207 houses have been authorized in rural areas, and 15,818 have been completed.

The Parliamentary Indian Committee was informed on March 9th that the Government proposed to introduce legislation giving effect to the main recommendations of the Lee Commission on the Indian Civil Services. Whether the recommendations in regard to the Indian Medical Service would be accepted was not specifically stated.

The Medical Committee of the House of Commons met at the House of Commons on March 9th and appointed Sir Richard Luce to act as liaison officer between the Committee and the British Medical Association, particularly in regard to the Factories Bill and any action on birth control. The Committee decided further to consider the Births and Deaths Registration Bill prepared by Dr. Fremantle. It decided to take no action on a communication received with regard to a recent removal from the *Medical Register*.

Members who are interested in the claims of certain classes of unregistered practitioners, to which attention was drawn in the House last week, will probably meet about March 31st. No deputation to the Minister of Health has yet been arranged.

## Correspondence.

### THE THYROID AND MANGANESE TREATMENT IN VARIOUS DISEASES.

SIR,—I am very much interested in the article on the above subject in your issue of March 7th (p. 443). For the last ten years or more I have been using potassium permanganate for various diseases, but mostly for "asylum dysentery." I used it, however, in a somewhat different way, as a solution of 1 grain to 20 ounces of water; of this the patient swallows doses of from 1/2 to 1 or 2 ounces several times a day. In urgent cases I use the same solution for an intramuscular injection, giving as much as will fill an ordinary 20-minim hypodermic syringe, which, of course, is more than 20 minims. This I inject deeply into the buttock. I have cases that were apparently almost moribund recover after this treatment. Some not only recovered from the dysentery, but from their insanity as well—in one case of melancholia after six years' illness. By a strange coincidence, this patient has just called to see me. She looks the picture of health and has been well ever since—that is, for four years.

I have also used colossal manganese for these injections. I have been rather diffident about *post* and *propter hoc*, but have told my medical friends. I see the names of two mental hospital physicians in Dr. Nott's list. Perhaps they will feel inclined, as I do, to adopt this treatment, so ably heralded by Dr. Nott, in cases of the toxic psychoses.—I am, etc.,

W. J. A. ERSKINE, M.D.,  
Medical Superintendent, Whitecroft Mental  
Hospital, Isle of Wight.

March 9th.

SIR,—In reference to Dr. Herbert W. Nott's interesting and suggestive article, it might interest your readers, and recall happy memories to many students of the late Professor Stephenson of Aberdeen University, if I write shortly upon Stephenson's teaching of over twenty years ago of the use of potassium permanganate in what he called the "blao type" of woman. I have used his treatment during my whole career as a general practitioner, and have never found it to fail. I use it in the form of pulverettes containing 2 grains each, and give one pulverette three times a day after food, the dose, and type of case, strictly following Stephenson's directions. The "blao type" is typified by a woman of between 18 and 25 years of age who comes to me complaining—

1. That she is readily tired. She starts out upon her day's work in quite good form and keen, but this feeling soon passes away, and before she has well started her work she is done up both mentally and physically.

2. She is not anaemic, but florid with "blao" lips, hands, and feet. If pressure is applied to her hands or feet, and released, the blood returns to the part very slowly.

3. She has a ready tendency to chilblains, and a puffiness about the ankles.

4. There is a sense of weight and soreness over the sacrum, especially when tired, and just before her periods.

5. The periods are irregular either as to periodicity or quantity or quality of discharge. Sometimes there is definite menorrhagia, and there is always pain just before the period and the first day of the period, but relieved by the period. Such patients are frequently quite unable to go about their ordinary duties when menstruating, or, if they do set out to work, have frequently to give in.

6. A very characteristic feature, when present, but not always present, is an intense, often occipital, headache upon the day preceding the expected period; the headache, as the condition progresses, tends to come on every second week, and ultimately weekly.

Such patients find life a heavy burden, are terribly handicapped in struggling to fulfil their daily duties, and I do not know any condition where relief evokes greater gratitude. I usually order a three months' course, but sometimes, as Stephenson warned us, the course has to be extended for a longer period. In certain cases there is a tendency to relapse, but a resumption of treatment rapidly brings about relief.—I am, etc.,

Tain, March 7th.

EDNA K. MACKENZIE.

## TUBERCULOSIS IN ASSAM.

SIR,—In a report of a paper read by Sir Leonard Rogers before the Section of Tropical Diseases and Parasitology of the Royal Society of Medicine on January 8th (BRITISH MEDICAL JOURNAL, January 17th, pp. 116-17), I was interested to read a statement based on gaol statistics that Assam, with the highest rainfall in India, had almost the lowest tuberculosis rate, and this was explained by the fact that, notwithstanding the heavy rainfall, the general configuration of the land protected the province from rain-bearing monsoon currents.

My own experience in the Cachar district of Assam is that rain-bearing winds and tuberculosis, especially pulmonary, are extremely prevalent. During the past five years pulmonary tuberculosis where tubercle bacilli were definitely found in the sputum represents 10 per cent. of the total mortality in my district.

As there are about twenty thousand coolies under my care in an area of about twenty miles, and as it is impossible to give individual attention to each patient, it is probable that tubercle bacilli were responsible for many more deaths than those recorded as due to this cause. Considering the high mortality from acute diseases, such as pneumonia, bacillary dysentery, cholera, malaria, etc., it will be seen that the relative percentage of deaths from pulmonary tuberculosis is extremely high. Tuberculosis is by no means confined to tea-garden coolies, for the local tribes—Kukis, Lushais, Nagas, Manipuris, and Cacharis—frequently come to me suffering from phthisis or other tuberculous infections.

The type of pulmonary tuberculosis in Cachar is usually a diffuse, rapid, caseating, necrotic type, with rarely haemoptysis, as was described by Arthur Powell in Bombay. With the exception of lupus, I have seen practically all types of tuberculosis in Assam which one sees in Great Britain. At present I have a boy 9 years of age under my care with renal tuberculosis where the diagnosis was confirmed by guinea-pig inoculation. Lupus is stated by some to occur only in those with a certain degree of resistance to the tubercle bacillus; but the impression one gathers in the tropics is that the action of sunlight on our bare-skinned or badly clad races is inimical to cutaneous tuberculosis.—I am, etc.,

G. C. RAMSAY.

Lahac Central Hospital, Dewan P.O.,  
Cachar, Assam, Feb. 14th.

## INFECTIVITY OF SMALL-POX IN THE INCUBATION STAGE.

SIR,—I quite agree with Dr. E. H. Snell (BRITISH MEDICAL JOURNAL, February 28th, p. 426) that the statement in Dr. Rolleston's valuable book on *Acute Infectious Diseases* (p. 326), that "the small-pox patient is infectious in all stages of the disease, even in the incubation period before any symptoms have appeared," is contrary to general experience. If Dr. Rolleston had qualified the statement by saying that small-pox might occasionally be infectious during any stage, but that it is not usually infectious until the rash appears, little objection could be taken; but in its present unqualified and dogmatic form it is certainly misleading and erroneous.

The following case, which has just occurred in my own experience, is, I think, typical of the experience of most medical officers of health, which justifies them in basing their preventive measures on the assumption that small-pox, with rare exceptions, is not infectious until the rash appears.

A married woman was taken ill with small-pox on February 15th; the eruption appeared on the 19th; she was removed to hospital on the 27th. Her husband, unvaccinated, shared the same bed at night throughout. He did not begin to sicken with the disease until March 4th—that is, the fourteenth day after the appearance of his wife's eruption. His eruption began to appear on March 8th.

Whilst one instance, of course, proves nothing, this case seems worth quoting, because the degree of contact must have been very close all through both the incubation and the prodromal periods, yet apparently he did not contract the disease until the eruption appeared.

I agree also with Dr. Snell that it is just this non-infectiousness of small-pox before the eruption appears which makes the prevention of small-pox comparatively easy (even in the absence of general vaccination), provided only that cases are promptly recognized and reported after the eruption appears.—I am, etc.,

Leicester, March 9th.

C. KILLICK MILLARD.

## ISOLATION HOSPITALS FOR SCARLET FEVER.

SIR,—I note that you do not wish this correspondence to drift into a discussion of the value of inunction in scarlet fever. It is, therefore, sufficient for me to point out that the Milne method of treatment has been discarded in the home of its birth, and an investigation into the results of it under Dr. Milne's régime and since was published by Dr. Gushue-Taylor, the medical officer who succeeded Dr. Milne, in the *Lancet* in 1923.

Dr. Robertson, the medical officer of health for Edinburgh, employs this objectionable treatment of swabbing the child's throat every two hours for twenty-four hours, not because inunction and swabbing is claimed by him to be "infallible treatment," but he has simply adopted it as "a reassuring influence of parental fears" in order to induce parents to retain their children at home rather than send them to an isolation hospital. When he tells us that in Leith a vast proportion of the cases treated on this system were in working men's dwellings, one can understand how little efficacious such treatment could be under such conditions. His results could as easily have been obtained without it. The policy adopted by Dr. Robertson, which saves cost to the rates, may appeal to the canny Scotsman; it makes little appeal to most other medical officers of health. Dr. Pringle, the medical officer of health for Ipswich, has summarized the position very ably when he says, "I believe that the local isolation hospital has contributed in no small degree to the low degree of prevalence of infectious disease at the present time. . . . In so far as the treatment of cases admitted is concerned, there is no question at all but that the hospital has been the means of restoring the health of large numbers of children and adults who could not possibly have received either adequate medical supervision or nursing management in their own homes."

If Dr. Robertson had confined his remarks to cases which could receive adequate nursing and medical attention in their own homes, and had discarded the Milne system, we should have had little dispute with him; but when he quotes with pride the percentage of cases treated at home at Leith, "the vast proportion of which were in working men's dwellings," I am inclined to think he is advocating economy at the expense of the health of the child.—I am, etc.,

Hford, Essex, March 4th.

A. H. G. BUNTON,  
Medical Officer of Health.

SIR,—Dr. H. Cameron Kidd's gentle protest does not persuade me that I missed the point of his letter. He ("purposely," he confesses) "said nothing on . . . the failings of isolation hospitals in respect to scarlet fever." But he asked that more money be spent on these institutions; and he expressed a conviction that "some of the complications" of scarlet fever "might" be avoided by such an outlay.

Now isolation hospitals cost a lot. The community is hard up at present. More expense must be justified by either proofs of valuable work done or a definite promise of increased efficiency. I regretfully suggest (a) that Dr. Kidd's conviction does not constitute such a promise, and (b) that his ingenuous omission of the question of the efficiency of hospital isolation does constitute a confession that these institutions are not exactly proud of their record. Thus it seems opportune and pertinent to interpose. The more so as Dr. Kidd now says, "We have committed our generation to hospital isolation, and the important thing is to make the best of it." Surely these are dangerous words. Efficiency is the test. And if we have committed our generation, knowingly, to anything less than first-rate, "the important thing" (pace Dr. Kidd) is to scrap it relentlessly.

You, Mr. Editor, deprecate "a discussion of the value of inoculation in scarlet fever"; but, unless the exponents of serum treatment or vaccine treatment can offer some definite hope, inoculation should be seriously investigated; and I am afraid that Dr. Kidd rather invites that ordeal by his reference to "old annual reports, especially twenty to twenty-five years ago, where the whole question was discussed." If he speaks by the book, a generation has now arisen which knows not the Milne method. Dr. Robertson's circular demonstrates anew that the thing can accomplish notable results in unpromising areas.—I am, etc.,

Belfast, March 2nd.

ROBERT WATSON.

### QUEEN'S HOSPITAL, BIRMINGHAM.

#### *Old Students and Residents Fund.*

SIR,—May I be allowed to use your columns for the purpose of bringing to the notice of the many past residents and students of the Queen's Hospital, Birmingham, the fact that an appeal is being made for funds to extend and reorganize the hospital? The need is great, and the appeal is meeting with encouraging support from the general public.

A strong desire has been expressed by many past students and residents of the hospital to associate themselves in some corporate manner with the appeal, and it has been suggested that a popular way of doing so would be to undertake to raise a sufficient sum of money to endow a bed in the new surgical block. The sum required is £1,250, and subscribers will have their names recorded over the bed, or in some other suitable position.

It is impossible to reach directly all past residents and students, who are widely scattered throughout the world; but any who may read this letter and would wish to record in permanent manner their affection for and appreciation of their *alma mater* by contributing to the "Old Students and Residents Fund" for the endowment of a bed are invited to send their donations to me, as treasurer of the Queen's Hospital Past and Present Residents' Association, at the Queen's Hospital, Birmingham.—I am, etc.,

Birmingham, March 8th.

L. KIRBY THOMAS.

### TREATMENT OF PERFORATED GASTRIC AND DUODENAL ULCERS.

SIR,—I have read with interest the letter on the treatment of perforated gastric and duodenal ulcers by Mr. Percival Mills (January 24th), but would ask if it is correct from a statistical standpoint to express results in percentage terms unless generalization is made on 100 cases or multiples of 100.

In my opinion it is incorrect, and I should like to have the opinion of statisticians such as Professor Karl Pearson and Dr. Major Greenwood on this.

If the 40 cases recorded were analysed in the manner used in the article quoted, in, say, batches of 10 taken seriatim, the "percentage" results obtained in each would, I venture, differ widely from those given in the article quoted, just as they would if they were expressed on a series of 100 cases, on which it would be statistically correct to generalize in percentages.—I am, etc.,

M. CONRX, Lieut.-Colonel I.M.S.,  
Civil Surgeon, Rawalpindi, Punjab,  
India.

February 4th.

### THE DIAGNOSIS OF PNEUMONIC PLAGUE.

SIR,—My reply to Dr. Dyce Sharp's question (December 27th, 1924, p. 1216) regarding the diagnosis between plague complicated with pneumonia and pneumonic plague is that the diagnosis depends on the physical properties of the sputum.

In plague complicated with pneumonia the sputum is very tenacious and viscid—at first blood-tinged, it becomes rusty; whereas in pneumonic plague the sputum is bloody and fluid, thus differing from the tenacious viscosity of

plague complicated with pneumonia. The honour of first establishing this point in diagnosis is, I think, due to my late teacher, the late Lieut.-Colonel Childe, I.M.S., Professor of Medicine, Grant Medical College, Bombay.—I am, etc.,

H. C. DE PENNING, M.R.C.S.,  
L.R.C.P.Lond.

Kotri, India, Jan. 23th.

### ANTHRAX-INFECTED SHAVING-BRUSHES.

SIR,—The calamity which you announce to-day, of Professor Ellermann's death from an anthrax-infected shaving-brush, induces me, as one of the English cases that recovered, to put forward once more a simple suggestion, already printed elsewhere.

I advise my friends never to buy any shaving-brush, but to use instead a small red rubber sponge, which, with good shaving-soap, is as good as a brush, costs far less, and, above all, is safe. I always now use one myself.—I am, etc.,

Exeter, March 7th.

W. GORDON.

### THE LATE SIR JAMES MACKENZIE.

SIR,—I think the chief lesson we are to draw from a consideration of the life of this great clinician is that a decentralization of medical studies is urgently needed. Hitherto it has been taken as axiomatic that the cutting edge of medical progress must necessarily be in the great cities. Sir James Mackenzie declared otherwise. Note the three successive phases of his career. First, over a quarter of a century at Burnley, where he learned the fundamental importance of the general and the practical approach to medicine, as embodied in the general practitioner. But he came to realize that this in itself was not enough, and that upon this broad basis of practical knowledge something further needed to be engrafted—namely, that which is ordinarily spoken of as science. Accordingly, we next find him a distinguished specialist in London, where he carried out his world-renowned work on the heart. But, contrary to what might have been expected, this eager searcher after truth did not remain in London. And why? I venture to think that it is in this "gesture," initiating his third phase, that the chief lesson to our age of Sir James Mackenzie's life is to be found. Why did London not satisfy his soul? Let us leave aside immediate reasons, which those personally acquainted with him will best know, and let us try to realize the deeper underlying causes. It looks as if he came to say to himself something like this: "The general atmosphere of the metropolis—its whole *Kultur*—is fundamentally devoid of, even inimical to, that co-ordinating vital principle which is the most urgent need of our art to-day. Of course, it is pre-eminently in the great city that we are to seek for those sciences which are the necessary ancillaries of medicine. But to make all this really practical—in a word, to effect the liaison, the co-ordination, the correlation of these disparate sciences with practice—we must go elsewhere."

Sir James Mackenzie went to St. Andrews—that is, to a small centre, which, although not the Burnley of his earlier years, yet contained all that was best in Burnley, and, in addition, all that was best in urban medical culture. At St. Andrews he found a proper commixture—a *eucrasia*—of the rural and urban. Is not the key to our problem perhaps to be found in this: that in the small centre it is at least possible to be in more or less continuous personal touch with one's patient, to see and deal with him as a continuum, both in space and time? Whereas in the great city we cannot deal with real persons, with persons in their entirety, in their natural settings—social, domestic, economic, etc.—but only with parts of persons, or with moments in their lives, or with moments in the lives of parts of them.

If, then, we would draw a moral from the career of this latter-day Sydenham, it would, I submit, be, not certainly *delenda*, but at least *subjicienda est Carthago*—and this, perhaps, not in medical matters alone.—I am, etc.,

Edinburgh, Feb. 6th.

A. J. BROCK.

## Medico-Legal.

## LUNACY LAW AND ADMINISTRATION.

HARNETT v. BOND AND ADAM.

THE appeal of Mr. W. S. Harnett, farmer, of Sittingbourne, Kent, from the order of the Court of Appeal reversing the judgement of Mr. Justice Lush which mulcted Dr. C. Hubert Bond, a Commissioner in Lunacy, in £5,000 as damages, for detaining the appellant at the office of the Commissioners, on December 14th, 1912, and both the same respondent and Dr. G. H. Adam, of Malling Place, Kent, a licensed home for the reception of lunatics, in £20,000 damages for an alleged joint tort whereby the appellant was returned to Malling Place, and was kept there, and at successive mental institutions, from October 14th, 1912, until October, 1921, when he escaped and was never recertified, came before the House of Lords on Monday. In the Court of Appeal it was held that Dr. Adam was protected by Section 330 of the Lunacy Act, 1890, and that a new trial should be confined to ascertaining the damages sustained by Mr. Harnett by his detention in the office of the Commissioners at the instance of Dr. Bond for from two to three hours on December 14th, 1912.

A report of the King's Bench proceedings will be found in the BRITISH MEDICAL JOURNAL of March 8th, 1924 (p. 449 et seq.), and of the proceedings in the Court of Appeal in the JOURNAL of April 12th, 1924 (p. 692 et seq.).

The appeal was heard by the Lord Chancellor (presiding) and Lords Buckmaster, Atkinson, Dunedin, and Sumner.

Counsel were:—For the appellant: Mr. S. Cope Morgan and Mr. J. W. Morris; for Dr. Bond: the Attorney-General, Mr. Harold Morris, K.C., Mr. W. Bowstead, and Mr. Harold Murphy; for Dr. Adam: Mr. A. Neilson, K.C., and Mr. T. Carthew. Mr. T. Simpson Pedler held a watching brief for the British Medical Association.

## The Pleadings.

The appellant's case was that the judgement of Mr. Justice Lush should be reaffirmed on the grounds (*inter alia*) that the learned judge was right in holding that it was a question for the jury to decide whether or not the detention of the appellant as a lunatic after December 14th, 1912, was the intended and/or natural and/or direct and probable consequence of the acts of the respondents, or either of them, and that the verdict of and damages assessed by the jury were reasonable and in accordance with the evidence; that the medical and other evidence showed that in no instance subsequent to the act of Dr. Bond was an adverse opinion concerning the appellant's mental state formed so independently as in law to constitute a *novus actus interveniens*; that such opinion was in each instance based upon the symptoms of excitement, resentment, and depression, which were the direct and natural consequence of the joint and/or several acts of the respondents, which constituted a joint tort; that the respondent, Dr. Adam, was guilty of a breach of duty for which the appellant was entitled to the damages awarded against Dr. Adam; that the condition attached by Dr. Adam to the Absence on Trial granted to the appellant under Section 55 of the Lunacy Act was without statutory authority, and that, alternatively, Dr. Adam was wrong in retaking the appellant, since his mental condition, as the jury had found, did not in fact require it; and, further, that Dr. Adam was wrong in retaking the appellant without first satisfying his own mind that the appellant's mental condition required it. In so acting, Dr. Adam was not entitled to claim that he acted in pursuance of the Lunacy Act, 1890, and, alternatively, the onus of proving the statutory defence under Section 330 (1) of the Lunacy Act, 1890, pleaded by Dr. Adam, lay upon him, and he had failed to discharge that onus. If the onus of proof lay upon the appellant, then he had discharged it. There was sufficient evidence to justify the finding of the jury that Dr. Adam did not take reasonable care in acting as he did, and the Court of Appeal was wrong in not ordering a new trial as against Dr. Adam. Finally, the order of the Court of Appeal as to the costs of the first trial against Dr. Bond was wrong and ought to be reversed.

Dr. Bond's case was that the judgement of the Court of Appeal should be affirmed, because Mr. Justice Lush had misdirected the jury on the question of damages. Any damage sustained after the appellant had returned to Malling Place on December 14th, 1912, and had been examined by Dr. Adam, was too remote and not recoverable in law from Dr. Bond, whilst the jury's minor apportionments of damage were merely the result of splitting up a sum arrived at on an inadmissible basis, and the sum of £5,000 as damages for the detention at the office of the Commissioners was excessive. The answers of the jury to the question whether the appellant on December 14th, 1912, (a) was of unsound mind, (b) was fit to be at large, (c) was dangerous to himself or others, and whether Dr. Bond honestly believed (a), (b), and (c), were against the weight of

the evidence, and there was no evidence that Dr. Bond did not honestly believe (a), (b), and (c).

Dr. Adam's case was that the judgement of the Court of Appeal ought to be affirmed because on the findings of the jury he was not guilty of any joint tort, and it was only upon the basis of his being guilty of a joint tort that the appellant could succeed. He was not guilty of any several torts. He had acted throughout in pursuance of the Lunacy Act, 1890, in good faith and with reasonable care, and was entitled to the protection of Section 330 of that Act, there being no evidence proper to be left to the jury that he acted without good faith and without reasonable care. In any event, the learned judge misdirected the jury as to damages, which were too remote.

## Hearing in the House of Lords.

Mr. Cope Morgan related the facts of the case, and pointed out that the action was one of damages for false imprisonment, and Dr. Bond admittedly had no defence.

Lord Atkinson: For the whole period?

Mr. Morgan: Certainly for the period Mr. Harnett was detained in the Commissioners' office.

Lord Buckmaster: Did he, in fact, try to get out of the office and was he prevented?

Mr. Morgan: Yes; he tried to get out to lunch; that has not been disputed.

Mr. Morgan said the action was not laid in negligence as was the case in *Everett v. Griffiths* (1921), 1 A.C. 631, and he emphasized that fact because the case had aroused widespread feeling on the part of the medical world, who supposed that the judgement of Mr. Justice Lush laid it down that any doctor who made a mistake in the course of diagnosis may be made liable for damages to a considerable amount. The Attorney-General (then Sir Patrick Hastings), in the Court of Appeal, had said that the real importance of the case was that it would be, practically speaking, impossible for a medical man to send a person who was a lunatic to an asylum if the law truly be that if he were found negligent in signing a certificate, he would be responsible in damages for the whole period during which the alleged lunatic was detained—that the effect of the judgement would be that nobody would ever sign a certificate and no one would keep anybody in a strait jacket: "We shall get the place flooded with gentlemen who ought to be in asylums because there is no protection at all for the doctor."

Lord Atkinson: If the doctor exercises reasonable skill and caution and signs a certificate is he guilty of false imprisonment?

Mr. Cope Morgan: No; and I am not suggesting that against the doctors who subregatally signed certificates in the long chain of years.

It was admitted that Dr. Bond had no more right to do what he did than he (counsel) had. Dr. Bond could not plead Section 330, but Dr. Adam did, and the jury specifically found that he had not exercised reasonable care. The Court of Appeal's proposition was that however rightly or wrongly a man was first sent to a lunatic asylum, then a Chancellor's visitor who saw him in the course of seeing 300 patients or so a day was to be regarded as a *novus actus interveniens*. Surely this must cover the case of a man sent to an asylum as the result of a tissue of lies as to his state of mind, due really to drugs administered by relatives who wanted to get rid of him, and who was consequently certified by medical men—if these certificates were each to be regarded as a *novus actus interveniens*, then it was plain that the original wrongdoers could not be made liable for the subsequent detention.

Mr. Cope Morgan dealt with the questions and answers of the jury, which were as follows:

1. Did Dr. Bond cause the plaintiff to be detained at the office until the attendants came for him?—Yes.
2. Did he cause him to be sent back for the purpose only of his being examined by Dr. Adam, or for the purpose of his being detained at Malling Place?—Being detained at Malling Place.
3. Did Dr. Bond cause the plaintiff to be taken back?—Yes.
4. Was the plaintiff of unsound mind on December 14th, 1912?—No.
5. Was he fit to be at large?—Yes.
6. Was he dangerous to himself or others?—No.
7. Did Dr. Bond honestly believe that the plaintiff was of unsound mind?—No.
8. Or that he was not fit to be at large?—No.
9. Or that he was dangerous to himself or others?—No.
10. Did he believe that the plaintiff had escaped from his brother's charge?—Yes.

[Mr. Cope Morgan here commented: It is common ground that the answer to Question 10 is explanatory of the answers to Questions 7, 8, and 9, the effect of the four answers being that Dr. Bond acted for the reason given in Question 10, and not because of any belief, honest or otherwise, concerning the applicant's state of mind.]

11. Did he take reasonable care to ascertain the true facts?—No.
12. Did he honestly believe that Dr. Adam had retained a power of taking the plaintiff back during the twenty-eight days in the Leave of Absence Order?—Yes.

13. Did Dr. Adam, when he received the telephone message and sent the car, honestly believe that the plaintiff, on December 14th, was of unsound mind and unfit to be at large?—Yes.

14. That it was in his interest that he should be taken back to Malling Place?—Yes.

15. Did he take reasonable care in acting as he did?—No.

[Question 16 was omitted.]

17. Was the detention of the plaintiff at the Commissioners' offices the act of Dr. Bond alone, or was it really the act of both the defendants?—Dr. Bond.

Lord Buckmaster observed that the Court below limited the measure of damages against Dr. Bond to the return of Mr. Harnett to Malling Place, and asked, What alternatives were there?

Mr. Cope Morgan submitted that there were four: (1) for the whole period of detention; (2) to January 9th, 1913, when the Absence on Trial Order properly expired; (3) to February 22nd, 1913, when Mr. Harnett was transferred from Malling Place to Croydon; (4) to November 10th, 1913, when the original reception order should normally have been renewed.

The hearing is continuing.

## LOSS OF SIGHT OF ONE EYE AFTER ANAESTHESIA.

MURDOCK v. HOLMES AND TAYLOR.

A CASE of considerable importance to the medical profession was heard at the Leicester Assizes on February 28th and March 2nd and 3rd, before Mr. Justice Rigby Swift. The plaintiff, George A. Murdock, hosiery manufacturer of Leicester, sued Drs. W. Moffat Holmes and George Taylor, practising together in partnership, for damages for the loss of the sight of his left eye alleged to be due to their negligence during the administration of an anaesthetic for an operation. The defendants did not admit liability and denied the allegations.

Mr. Bernard Campion, K.C., and Mr. J. P. Stimpson appeared for the plaintiff, and Mr. Norman Birkett, K.C., with Mr. Maurice Healey, for the defendants. Dr. Holmes's defence was undertaken by the London and Counties Medical Protection Society, and Dr. Taylor's by the Medical and Dental Defence Union of Scotland.

### Case for the Plaintiff.

Counsel, in opening the case for the plaintiff, said that about March 6th, 1924, Mr. Murdock was seized with abdominal pain due to appendicitis, and Mr. Bolton Carter, a surgeon, was called into consultation with the two defendants. An immediate operation was ordered, and was successfully performed the next day by Mr. Carter at the Highfields Hospital. Both the defendants were present, Dr. Taylor giving the anaesthetic. When plaintiff came round he complained of pain in his left eye. This continued, and on March 14th Dr. Holmes called in Mr. Ridley, an ophthalmic surgeon, who found that parts of the eye were very badly scarred. Counsel added that the eye was now blind, all that remained by way of sight being the perception of light. As to which of the two defendants was responsible did not matter, for they were in partnership and both were liable.

The plaintiff, in the course of his evidence, said he had acute pain in the eye for six or seven weeks after the operation. In reply to the judge, he said that the defendants had not told him that it was the anaesthetic that had done the mischief. In cross-examination by Mr. Birkett, he agreed that his illness had brought him to the "very gates of death." He did not know that any of the anaesthetic went into his eye; he only knew "what the doctors admitted."

Mr. N. C. Ridley, consulting ophthalmic surgeon, Leicester Royal Infirmary, said that when he first saw the eye there was slight inflammation. The patient was in a bad condition—so bad that it did not matter about the eye, and Mr. Ridley thought he was dying. The condition of the eye was consistent with some of the anaesthetic having got into it. It was a frightfully common thing for some of the anaesthetic to get into the eye during an operation, but the patient did not then generally lose the sight of the eye. Witness took it that what might cause little or no injury in a healthy person had produced in this patient a destruction of the eye tissue. He thought the plaintiff somewhat exaggerated the amount of loss of sight. In cross-examination Mr. Ridley said that this was the only case of the kind in which he had known serious results occur, and added that the accident might have happened, no matter how much care was taken.

Dr. T. E. A. Carr and Dr. A. D. Hunt of Derby were both called for the plaintiff, the former speaking from the ophthalmic surgeon's point of view, the latter as one who had had very large experience as an anaesthetist. Dr. Hunt explained the precautions he took to avoid getting any anaesthetic into a patient's eye, and the measures he would take to remedy such a mishap. He had never known a case so serious as this. This closed the case for the plaintiff.

### Case for the Defence.

Mr. Birkett, in opening for the defendants, submitted that there was no case of negligence, and that there was no evidence whatever suggested against Dr. Holmes. His lordship said he was impressed with this argument in favour of no negligence on the part of Dr. Holmes; but Mr. Campion argued otherwise, and the judge then said that the case would have to go to the jury.

On the resumption on March 2nd Mr. Healey addressed the jury for the defence, submitting that there was no definite piece of evidence to justify the jury coming to the conclusion that one drop of liquid came near the plaintiff's eye, and that at no time during the operation could anything have been done to prevent this injury. Counsel pointed out that during the operation there were eight persons in the room—three doctors, the patient, and four trained nurses—yet none of the nurses had been called to say what carelessness the anaesthetist had been guilty of. Nothing that a skilful administrator would have done was left undone.

Dr. Taylor, giving evidence, said he had administered an anaesthetic thousands of times, and, after describing the precautions taken by him during operations, demonstrated the method of anaesthesia adopted in that case. There were, he said, no signs during the operation of any anaesthetic having got into the eye; he always covered the whole of the face, including the eyes, with a pad. In this case he changed the pad once during the operation because it was getting damp.

Dr. R. Wallace Henry, ophthalmic surgeon of Leicester, said he agreed with the evidence given by Mr. Ridley. While the anaesthetic might have been the immediate cause of the eye condition, the main cause was the anaesthetic acting on an eye in a toxic condition. He did not think that it was possible to stop vapour from getting into the eye.

Dr. J. Blomfield, anaesthetist to St. George's Hospital, London, expressed the opinion that no anaesthetic could get into an eye without there being any lack of care or skill.

Mr. F. Bolton Carter, surgeon to the Leicester Royal Infirmary, who performed the operation, said that the patient's condition before operation was extremely serious. It was only through the great care he received that he lived. There was no evidence that any liquid anaesthetic had got into the eye. With considerable experience of anaesthetics he declared that Dr. Taylor gave the anaesthetic remarkably well and skilfully. In such a case it was essential for the patient to be deeply under, and this would entail saturating the mask with the anaesthetic. Mr. Carter added that there was an epidemic of "pink eye" or "anaesthetic eye" at the Leicester Royal Infirmary last year, and an inquiry was held. The anaesthetics were administered by two highly experienced men, who were absolutely certain that in none of these cases had the liquid anaesthetic got into the eye. In the majority of the cases the patients were in a septic condition. The eye trouble in these patients cleared up within three or four days, except in one case, in which the eye had to be removed.

Dr. Holmes, one of the defendants, said he assisted Mr. Carter at the operation; he did not observe Dr. Taylor in giving the anaesthetic, and he had nothing to do with its administration. When he examined plaintiff's eye after the operation he attributed the inflammation to the anaesthetic vapour; there was much vapour about.

Dr. M. H. Barton, honorary ophthalmic surgeon, Leicester Royal Infirmary, said he had seen eyes in the condition like that of the plaintiff without the patient ever having an anaesthetic. The scar on plaintiff's eye was consistent with its having been caused by vapour and not by liquid. But vapour alone would not have caused the trouble in this case, and he agreed with Mr. Carter that the main cause was a germ. The next witness, Miss Evans, sister at the Highfields Hospital, said she observed nothing abnormal about the giving of the anaesthetic.

His Lordship said there was not the slightest evidence of personal negligence against Dr. Holmes; his reputation was absolutely clear; but he remained in the case as partner of Dr. Taylor.

### Summing Up.

In the course of his summing up, Mr. Justice Rigby Swift said that the plaintiff had had the advantage of the best medical and surgical skill which could be obtained for him in Leicester, and fortunately his life was saved. Whether in the end the jury came to the conclusion that anyone was responsible for the injury to the eye, they must consider whether a case of negligence had been made out. Before plaintiff could get any damages they must be satisfied that he had experienced a very terrible injury and one for which, if he was to be compensated at all, he must be compensated by a very large sum of money. Here was a business man, getting past the prime of life, who said he was now unable to lead an active life and take complete control of his firm's works. If this were so, then the compensation should be very substantial, although, measured in pounds, shillings, and pence, no money the jury could give him would restore his blinded eye and put him back again as he was before the accident. If plaintiff was entitled to any damages, the jury must in arriving at the figure consider what had been done to him, not how much the defendants could afford to pay, nor what the consequences to the defendants would be if the verdict went against them. Before finding for the plaintiff the jury must be satisfied that in the administration of the anaesthetic Dr. Taylor did something which a reasonable person would not have done; they must not find for the plaintiff out of sympathy.

### The Jury Disagree.

After an absence of an hour and three-quarters the jury returned to court and informed the judge that they were unable to agree. They then retired for eighteen minutes more, when the judge was again informed that agreement was impossible. The jury returned again and were discharged.

## DIAGNOSIS OF DISLOCATION.

FREEBORN v. LEEMING.

DAMAGES amounting to £1,800, together with the costs of the action, were given by His Honour Judge E. H. Chapman, in the Grimsby County Court on February 18th, against Dr. R. W. Leeming of Kendal for negligence in failing to diagnose the dislocation of the left hip-joint of George Freeborn, formerly a travelling ganger, of Scunthorpe.

It appeared that at about 9 p.m. on September 5th, 1923, two policemen found the plaintiff on the road near Kendal in such a condition that he was unable to walk without help; he was charged with simple drunkenness and removed to a cell, where

he was left lying on a plank bed. Dr. Leeming, the police surgeon, was sent for the following morning, as the plaintiff complained of pains in his leg, and, having examined the plaintiff, ordered his removal to the Poor Law infirmary, of which Dr. Leeming was medical officer. The plaintiff remained under defendant's care until October 15th, 1923, when he left for his home at his own request, and, on the following day, his own medical attendant, Dr. Johnston, examined him and suspected a fracture of the neck of the femur. Dr. W. M. Shepherd, consulting surgeon, of Doncaster, was called in, and he came to the conclusion that the plaintiff was suffering from an unreduced dislocation of the left hip-joint. The plaintiff was thereupon removed to the Doncaster Royal Infirmary, and, as the result of an operation on November 18th, the plaintiff's left leg was now one inch shorter than the other, and, according to medical evidence, would always be somewhat shorter and always so weak that the plaintiff would never again be able to do hard work.

The plaintiff's case was that his hip was dislocated on September 5th, 1923, as the result of being run into by a car shortly before he was picked up by the police, and that his permanent disability was due to the defendant's failure in diagnosis.

The defendant contended that there was no dislocation of the left hip-joint, either on September 5th, 1923, or at any time while the plaintiff was under his care. He admitted, however, that on November 3rd, 1923, there was such dislocation, but this, he contended, took place at some time between October 15th, the day on which the plaintiff left the infirmary, and November 3rd.

His Honour, in giving judgement, said he was not satisfied that the plaintiff was drunk on the night of September 5th, although he thought the plaintiff's condition was partially due to the drink he had taken. There was a direct conflict of evidence as to whether the plaintiff told the defendant he had been run into by a car, but a police witness had said: "On the night of the accident the plaintiff answered questions all right;" whilst Nurse Knott said: "Freeborn asked me to ask the doctor not to state in the certificate that he was drunk at the time of the accident or he would not get the money." The defendant admitted signing a certificate on September 6th, in which he certified that Freeborn was suffering from severe bruising of the left thigh, the result of an accident, and a further certificate on October 12th, 1923, stating that Freeborn was unable to follow his employment owing to injuries received from a motor car on September 5th. His Honour, therefore, was of opinion that the plaintiff was injured by an accident with a motor car on September 5th, 1923, and that on the following day the plaintiff did inform the defendant of such accident. The defendant was bound to bring to the plaintiff a fair, reasonable, and competent degree of skill and care; and he (his Honour) came to the conclusion that the defendant was negligent in each one of the particulars alleged, except the one of "disregarding the plaintiff's complaints that the bones were injured." He found that the defendant was not negligent in that respect, for he was not satisfied that the plaintiff ever complained that the bones were injured. As to the defendant's plea that the action had not been brought within six months of the cause of action accruing—a protection afforded by the Public Authorities' Protection Act, 1893—his Honour held that the cause of action arose after November 1st, 1923, and that therefore the action was started (April 25th, 1924) within the six months. As to damages, the plaintiff was a strong, healthy man, aged 53, and his wages were £6 a week. If he had been properly treated from the first he would have been laid up for six weeks, and would have been fit for light work in about three months after the date of the accident, and eventually have recovered the full use of his limbs. As it was, the plaintiff was left with one leg permanently shorter than the other and permanently weak, and was still unable to walk without the help of crutches, although it was hoped he would be able to dispense with these in five or six months' time. In his opinion, the plaintiff should not be prejudiced in respect of damages in view of the fact that had it not been for lack of funds the case would have been tried in the High Court, from which it had been remitted.

## Universities and Colleges.

### UNIVERSITY OF CAMBRIDGE.

#### Pinsent-Darwin Studentship in Mental Pathology.

This studentship was founded in 1924 by the bequest of Mrs. Pinsent and Sir Horace and Lady Darwin for the purpose of promoting research into any problem which may have a bearing on mental defects, diseases, or disorders. The studentship is of the annual value of about £200 and is tenable for three years in the first instance. The student may be of either sex, and need not be a member of the University of Cambridge. He will be required to engage in original research in Cambridge or elsewhere, but may, subject to the consent of the managers, carry on educational or other work concurrently. Further particulars of the studentship may be obtained from the Registrar of the University of Cambridge, and applications for appointment to the studentship should be sent before May 1st to the Secretary, Pinsent-Darwin Studentship, Psychological Laboratory, Cambridge. Applicants should state their age and qualifications and the general nature of the problems in which they are interested, and should give the date at which they would be prepared to begin work if appointed. No testimonials are required, but applicants should give the names of not more than three referees.

### ROYAL COLLEGE OF SURGEONS OF ENGLAND.

#### COUNCIL ELECTION.

THE secretary of the College of Surgeons has sent out the usual announcement, which, on this occasion, states that a meeting of the Fellows will be held at the College on Thursday, July 2nd next, at 2.30 p.m., for the election of three Fellows into the Council in the vacancies occasioned by the retirement in rotation of Mr. V. Warren Low, C.B., Mr. James Sherren, C.B.E., and Sir John Lynn-Thomas, K.B.E., C.B., C.M.G.

Blank forms of the requisite notice from a candidate and of his nomination may be obtained on application to the secretary, and the same must be received by him duly filled up within ten days from this date—that is, not later than on Monday, March 16th. A voting paper will be sent by post to each Fellow whose address is registered at the College on March 31st. Fellows are requested to give notice, without delay, of any change of address, so that voting papers may not be mis-sent.

## Obituary.

### JOSEPH ARDERNE ORMEROD, M.D., F.R.C.P.,

Registrar of the Royal College of Physicians of London;  
Consulting Physician, St. Bartholomew's Hospital and  
the National Hospital for the Paralysed and  
Epileptic, Queen Square.

By the death on March 5th, after an operation for a perforated duodenal ulcer, of Dr. J. A. Ormerod the Royal College of Physicians of London has lost its able and devoted registrar, a scholar, and a lover of its traditions, who was at his usual work as lately as February 27th.

He was born on April 7th, 1848; he was the second son of the Venerable T. J. Ormerod, Archdeacon of Suffolk, and came of an old and distinguished Lancastrian family; his grandfather, George Ormerod, F.R.S., of Tyldesley and Sedbury Park, the historian of Cheshire, married Sarah, the daughter of John Latham, M.D., F.R.S., President of the Royal College of Physicians (1813-19), and father of Peter Mere Latham. Of George Ormerod's seven sons and three daughters four obtained a niche in the *Dictionary of National Biography*: George Wareing Ormerod was a well known geologist; William Piers Ormerod, anatomist, surgeon, and sanitarian, and Edward Latham Ormerod, who, like his nephew, was demonstrator of morbid anatomy, were educated medically at St. Bartholomew's Hospital; Eleanor Anne Ormerod earned a deservedly high reputation as an economic entomologist, and was the first woman to receive the honorary LL.D. of Edinburgh. Dr. Ormerod's eldest son, Major George Ormerod, D.S.O., is chief constable for East Essex; his second son, Henry Arderne Ormerod, M.C., is professor of Greek in the University of Leeds and author of *Piracy in the Ancient World*; one of his daughters is married to Dr. J. B. Christopherson, C.B.E., F.R.C.P.

Following in the footsteps of his father and uncles, Ormerod went in 1862 to Rugby and in 1867 to Oxford, where he was a classical scholar at Corpus, being placed in the first class in moderations (1869), in the second class in *litteris humanioribus* (1870), and, after deciding to follow the physio life, in the first class in natural science (1871); in addition he won the Chancellor's prize for Latin verse (1869) for "Exercitus Indo-Britannicus ex Abyssinia Redux," and a Fellowship at Jesus College (1871).

Entering the medical school of St. Bartholomew's Hospital in October, 1872, he qualified B.M.Oxford in 1875, proceeding to the D.M. in 1882 with a dissertation "On epilepsy in its relation to ear disease," and after holding a number of appointments, including medical registrar and demonstrator (1887), was elected assistant physician (1893), physician (1904), and consulting physician (1913). He was also physician to out-patients (1878) and physician (1888-93) to the City of London Hospital for Diseases of the Heart and Lungs, Victoria Park, where he interested himself in laryngology, and assistant physician (1880), physician (1900), and consulting physician (1913) to the National Hospital for the Paralysed and Epileptic, Queen Square, where, as secretary of the medical staff, he did yeoman service in smoothly settling the impasse that arose between the staff and the lay board in 1901. During the war he was physician to King George Hospital, Stamford Street. His bent in medical work was mainly neurological; in 1892 he

brought out *A Student's Guide to Nervous Disease*, and his abilities were rightly recognized by his election as president of the Neurological Section of the Royal Society of Medicine (1910-11), where his presidential address dealt with "Two theories of hysteria," that of Pierre Janet and that of Breuer and Freud. Among his published papers, more than a score of which appeared in *St. Bartholomew's Hospital Reports* and more than a dozen in *Brain*, attention may be drawn to those on the myopathies and to his account of a case, in 1890, of what is now known as progressive lenticular degeneration or Wilson's disease, in which the cirrhotic condition of the liver was recognized, and to his articles in the *System of Medicine* on cerebro-spinal fever, tabes dorsalis, and hysteria.

At the College of Physicians, with which the later part of his life was closely associated, he became a Member in 1877, a Fellow in 1885, delivered the Harveian Oration in 1908 on "Heredity in relation to disease," and the Lumleian Lectures in 1914 on "Some modern theories concerning hysteria"; was appointed assistant registrar in 1908, and in the following year succeeded the late Dr. E. Liveing as registrar. He also examined for the Conjoint Board (1907-8), and was on the Council (1903-5). Like his late colleague, Sir Norman Moore, whose obituary notice he wrote in *St. Bartholomew's Hospital Reports*, he was by education and tastes admirably fitted to be an official of the College of Physicians. Further, his orderly mind with a lawyer's keen sense for possible pitfalls and fallacies, his power of hard work, and his knowledge of the statutes, by-laws, and regulations of the College, made him peculiarly suitable to be its registrar. Few realize how much falls on the holder of this office, not only at the College, but in connexion with the board of management of the Conjoint Examining Board in England. His shrewd common sense was eminently shown in statements drawn up for decision by the legal advisers of the College. He certainly had no love for change merely for the sake of change; he was indeed somewhat critical of any alteration in the laws, and was properly zealous of any infringement of the rights of the College to which he was so deeply attached. When any change was made he carried it out most loyally and cheerfully.

A most considerate and unselfish colleague, he was entirely wanting in self-assertive dogmatism and often seemed loath to differ at first from others, as if for fear of hurting their susceptibilities; but, while most conciliatory, he eventually always made his point of view quite clear. Extremely modest and reticent, his strength of character was not always obvious to those who did not know this upright and kindly gentleman. Although he had a trying illness in the latter half of last year and had the misfortune of losing his wife two months ago, he retained to the end an appearance of a man much younger than his age, and this may well have been connected with the freedom from any feelings save those of kindness towards his fellow men.

H. R.

CLAUDE BUCHANAN KER, M.D., F.R.C.P.,  
Medical Superintendent, City Hospital, Edinburgh.

His death occurred on Wednesday, March 4th, of Dr. Claude Buchanan Ker. Dr. Ker had been in his usual health up to February 25th, when he showed symptoms of an influenza attack, during which a severe form of bronchopneumonia developed, and under this he gradually sank. He had been for twenty-eight years medical superintendent of Edinburgh City Hospital, and in this capacity acted as university lecturer on infectious fevers from 1904 onwards. Thus he had become well known to many successive classes of medical students, by whom he will be universally missed.

After graduation as M.B., C.M. in 1890 he acted during the summer of 1891 as resident surgeon in the Royal Infirmary with Dr. Peter MacLaren, and later became resident surgeon in the Royal Maternity Hospital, Edinburgh, and clinical assistant to the lock and observation wards of the Royal Infirmary. For a time also he acted as assistant medical officer at the Edinburgh Fever Hospital. In 1891 he gained the certificate of the Medical-Psychological Association of Great Britain, and in 1895 he

graduated M.D. at Edinburgh University, receiving a gold medal for his thesis. In 1891 he joined the Royal College of Physicians as a Member, proceeding to the Fellowship in 1901. He became medical superintendent of the City Hospital for infectious disease while it was still situated in High School Yards, and was transferred to the new hospital at Colinton Mains when it was opened in 1903. Here his activities had been centred for the last twenty-two years, and he had devoted himself with great ardour and success to the investigation and treatment of different types of infectious diseases. For several years before his death he was a member of the council of the Royal College of Physicians, and two years ago he was elected a representative of the College on the board of management of the Royal Infirmary, Edinburgh.

His *Manual of Fevers* attracted widespread attention when it appeared first in 1909. A second edition was published in April, 1920. This came to be recognized as one of the most authoritative manuals on the subject in the English language. It was followed by the smaller *Infectious Disease: A Practical Textbook*, intended for the use of students, which attained an even greater degree of popularity. In these manuals his personal opinions, derived from wide experience, are chiefly found. In addition to these, occasional papers emanated from his pen upon the naphthols in enteric fever, on isolation and quarantine periods, and on the question whether there is a "fourth disease."

Dr. Ker was a lucid, stimulating, and erudite teacher, whose lectures enjoyed great popularity with his students. His opinions, whether expressed at meetings of the profession or at individual consultations to which he was widely called, were always received with great respect and attention. The Edinburgh medical school will be much poorer by reason of his loss.

He is survived by a widow, two sons, and three daughters. The interment took place on March 7th in the Morningside Cemetery, Edinburgh, and was attended officially by the Fellows of the Royal College of Physicians, as well as by a large number of friends and representatives of the medical profession.

We are indebted to Dr. ANDREW BALFOUR for a tribute to Dr. Ker's memory, from which we extract the following:

Ker was intensely alive, intensely human, full of humour and sympathy, and utterly devoid of anything savouring of advertisement or self-seeking. Withal he was a man of great force of character, with strong likes and dislikes, and capable, very capable, of standing up for what he conceived to be the right. Yet he very rarely found himself in conflict, for he possessed much tact and discretion and a store of patience which time and again stood him in good stead. I first met him in 1895 when, having been appointed assistant physician at the Edinburgh City Hospital, I called at the Old Pest House, as we called it, at the foot of Infirmary Street, to be interviewed by the medical superintendent. He had recently been appointed to the post. I was shown into a small room, and presently there entered with a brisk step and a curious swing of the body a man of medium height, who wore a monocle, through which an eye afflicted, though not unpleasantly, by an internal strabismus, surveyed me searchingly. He wore a blue velvet tasselled skull cap, was clad in a long white overall, and carried a wooden stethoscope of prodigious length. He spoke like an Englishman, kept flicking cigarette ash on the floor, and his manner was decisive, even a little brusque. He seemed to me rather nervous, and I gathered he did not quite approve of my appointment, which had been made at the instance of Sir Henry Littlejohn. Certainly he made it quite plain that I was there to carry out his instructions, though he indicated, also quite clearly, that he realized I might have views of my own, and that he was prepared to accord them every consideration. As I told him long afterwards, my first thought was, "How can I work under this man?" Yet very soon I had fallen, as did all his assistants and all his residents, under the spell of his personality. I had some slight acquaintance with French history, and I found that Ker was a great student of the Napoleonic era, and was never tired of hearing him descant on Bonaparte's strategy and recounting how he had secured the prints, statuettes, and relics with which his room was filled. Beyond doubt, he might have been an admirable professor of military history, for he had a flair for tactics. It was probably his military bent which led him to take a commission, first in the Volunteers and then in the Territorials. I found he was interested in sport and athletics, especially in

Rugby football. Above all, he had a keen sense of humour, and could write most amusing and delightful letters, either in verse or prose. We soon formed a friendship which stood the test of time and distance, the memory of which will ever remain precious and fragrant.

Ker had a host of friends. It was the custom then, and I understand it remained a custom, for his old residents to gather in his room on Sunday evenings and discuss all manner of things. He was ever the life and centre of these reunions. Not infrequently they took the form of discussions on fever cases and medical problems, and, as Ker's knowledge of fevers increased, so did the value of his expositions. No more profitable evenings can be imagined than these informal gatherings in the venerable building, full of memories of Sir Walter Scott, of the anatomist Knox, and of Burke and Hare, the West Port murderers. In those early days I was privileged to get some insight into his views and his schemes for the future. With Baillie Pollard, convener of the Public Health Committee, he spent hours in planning the new hospital which was to be built at Colinton, facing those Pentland Hills for which he had an affection almost equalling that of Robert Louis Stevenson. He entered upon the task with enthusiasm, and it cannot be doubted that it was largely due to his efforts that the present City Hospital became a credit to Edinburgh, while it is undoubtedly due in the main to him that it attained such a high degree of efficiency. No man was ever more popular with his staff. He had a way of getting the best out of them, and set an example of devotion to duty and of tireless, yet painstaking, energy which acted as a stimulus to all. He was a member of a small literary club which, beginning as the Heptagon, became an Octagon. Its membership was confined to a few medical men who met at each other's houses. Here, again, Ker was the life and soul of the party. He never missed a meeting throughout the twenty-five years of the club's existence, and, at the last but one, a full meeting to celebrate its twenty-fifth anniversary, he broke one of its rules, with the full consent of the members, by declaiming an ode which he had composed for the occasion, and which revealed considerable poetic talent. It was agreed to have a similar reunion in ten years' time, but alas! that hope can never be realized. There are many who mourn his loss, and his memory will remain ever green in the hearts and minds of those who knew his sterling worth and valued his company and his friendship. The world to-day, and his own world of Edinburgh in particular, seems woefully the poorer because Claude Buchanan Ker has passed to his well earned rest.

**J. J. GRAHAM BROWN, M.D., F.R.C.P.Ed.,**  
Consulting Physician, Edinburgh Royal Infirmary.

THE announcement of the death of Dr. J. J. Graham Brown, which took place on February 28th at his residence in Edinburgh, has been received with deep regret. He had been ill for some time, and his death occurred shortly after an operation.

Graham Brown graduated M.B., C.M. in 1875, and afterwards became resident medical officer in Chalmers's Hospital, Edinburgh, and later acted as resident physician in the Royal Infirmary to Sir Thomas Grainger Stewart, and in the following year as resident surgeon to Professor Spence. At the same time he was elected senior president of the Royal Medical Society, in the affairs of which he took a great interest. After a year spent at medical schools on the Continent, he returned to Edinburgh and took the degree of doctor of medicine in 1878, and joined the Royal College of Physicians of Edinburgh as a Fellow in 1882; later in life he was its president. In 1885 he went, in company with Professor Sir Charles Sherrington and Professor C. S. Roy, to Spain as member of a commission which had been appointed by the Royal Society of London to investigate an epidemic of cholera then prevailing in that country. During these early years he interested himself mainly in scientific investigation, and his work done in collaboration with Professor Roy, on the capillary blood pressure, is particularly well known. The subject in which he specially interested himself was, however, neurology, and his distinction in this subject was recognized by the University of Edinburgh in his appointment to the lectureship on neurology, which was established by the university in 1909.

Among his publications were *A Manual of Clinical Methods*; and papers on change in the circulation produced by rise of temperature; on the perigraph, an instrument for delineating the shape of the thorax; on ataxia;

on asthma, its pathology and treatment; and on sthenic dyspepsia, most of which appeared in the *Edinburgh Medical Journal* at various times.

In 1897 he was appointed an assistant physician to the Edinburgh Royal Infirmary, and he continued to serve in that capacity until 1912, when he became one of the ordinary physicians. He was a successful and painstaking teacher of clinical medicine for five years until 1919, when, on his retirement at the age limit, from the post of ordinary physician to the infirmary, he was appointed a consultant physician. He had been connected as medical officer with the Scottish Life Assurance Company since its inception, and was a recognized authority upon life insurance matters. A tribute to his eminence in neurology was his election in 1912, and again in 1918, by the Royal College of Physicians, Edinburgh, as Morrison lecturer on mental diseases for the year.

Dr. Graham Brown, who was a widower, is survived by three sons and one daughter; the eldest son is Professor T. Graham Brown, professor of physiology in University College, Cardiff. The interment, which took place in the Dean Cemetery, Edinburgh, on March 3rd, was attended by numerous friends and leading members of the medical profession.

**ALFRED J. SMITH, M.B., B.Ch., R.U.I.,**  
Professor of Midwifery and Diseases of Women, National University, Ireland.

WE regret to announce the death of Professor Alfred J. Smith, which took place recently, after a very short illness, at his residence in Dublin. Professor Smith was the son of the late Philip Smith, of Kevitt Castle, Crossdoney, County Cavan. He was educated at St. Patrick's College, Cavan, and at the Royal University in Dublin, where he graduated; he later pursued his professional studies at Leipzig, Berlin, and Vienna. He had been vice-president of the British Gynaecological Society and president of the Obstetric Section, Royal Academy of Medicine. He had held the office of Assistant Master of the Rotunda Hospital, of which institution he was licentiate (1884), and was professor of midwifery and gynaecology at the National University of Ireland, and gynaecologist to St. Vincent's Hospital, Dublin. He contributed many papers to various societies and journals on subjects that interested gynaecologists. Professor Smith was a great follower of sport in all its branches. He constantly attended Rugby football matches, and was a keen golfer; he was also a member of the Leopardstown and Phoenix Park Race Clubs. His death, at a comparatively early age, will be regretted by his many friends.

**THE LATE DR. T. L. BUNTING.**

IN our issue of February 28th (p. 433) we recorded with regret the death of Dr. Thomas Lowy Bunting. We have now received an appreciation contributed jointly by Dr. J. McCracken and Dr. H. Rutter, from which we quote the following extracts:

Dr. Bunting while at the University of Edinburgh became associated with Professor Patrick Geddes's work amongst the students, then just beginning, which grew into the Town and Gown movement, and had for its object to make the students take an interest in the welfare of the poor. This interest lasted with him all through his life. After leaving Edinburgh he went first to an asylum near Buxton, and thence came to Newcastle, where he joined the old Fabian Society, at that time the nursery of Bernard Shaw, Graham Wallas, Sidney Webb, and others who have since become famous. Then, as always, he took a deep interest in all social problems. Many of his colleagues remember long discussions on such subjects, from which, owing to his wide knowledge of every side of the matter, he always came off best; but these talks never cost him a friend, and it was their peculiarity that after them he was always on better terms with his opponents than before. In 1904 he proceeded M.D., gaining a gold medal for his thesis, which was on the histology of lymphatic glands—the general structure, the reticulum, and the germ centres. Little had been done in this field since the classic investigations of His, which had been accepted for very many years. But His had made his observations on the glands of the ox, the structure of which Bunting found to be peculiar to the species and very different from the arrangement really found in man.

Fortunately at that time there was a menagerie in Newcastle, and by securing the bodies of the animals that died there he was enabled to carry on his comparative investigations on a very wide scale. He completed this highly difficult research without any aid from a laboratory, and had to prepare his specimens, cut sections, and examine them microscopically in his surgery amid the constant interruptions incident to a large general practice. This thesis, as well as being rewarded by his University, gained him the distinction of being elected to the Royal Society, Edinburgh. Though Dr. Bunting had a most successful and useful life in other departments, yet he was never in his real element, and his most intimate friends know that any opening that could have led to his becoming a teacher and investigator of physiology would have allowed him to live his life to the full. He was first interested in medico-political matters through his being on the old Northumberland Contract Committee before it was taken over by the British Medical Association. From this he finally became a leading figure in the North-east of England as secretary of the Newcastle Panel Committee, one of the elected medical representatives on the Newcastle Insurance Committee, and secretary of the North-eastern Group of Panel Committees. The agitation in 1912 over the Insurance Act came to Dr. Bunting as a call for work on behalf of the profession. This led to his devoting an increasing amount of thought and time to medical politics until he became in Newcastle the guide and adviser of the Panel Committee in general and of many individual doctors in particular. It thus became generally realized, both by the doctors themselves and by the outside public, that he was a force to be reckoned with. By means of letters in the newspapers he clearly outlined the aims and position of the medical profession, whilst in the Insurance Committee he was able to clear away many misunderstandings and difficulties that otherwise might have led to serious friction. One striking characteristic in all that he did was his absolute conscientiousness, which he carried at times to a point to which few would have cared to go. He was very loyal as secretary of the Panel Committee and carried out its decisions, even against his own well informed judgement. The position he finally came to occupy among us was due to several causes. In the first place, his honesty of purpose and sense of justice was balanced by intimate knowledge and insight into medical politics; he thus was able when he spoke, not only to marshal facts and arguments, but also to keep in view the underlying principles that were involved.

#### ARMAND DE WATTEVILLE, M.D., Formerly Editor of *Brain*.

THE announcement of the death of Dr. Armand de Watteville will recall many memories to those who knew medical London in the fourth quarter of the nineteenth century. De Watteville lived a very full life for some thirty years, and then rather unexpectedly retired; after spending some time in Scotland he went to live in Switzerland. His family belonged originally to that country, but had been compelled to leave it during the revolution of 1797, and had settled in Great Britain; many of its members served in the British Army. Armand de Watteville was commonly spoken of as "Baron," and had, we believe, a good claim to bear that title. He was born in 1846, and was educated at King's College, University College, and St. Mary's Hospital. In 1870 he went with a British Red Cross ambulance, and subsequently served in a French Regular ambulance with the Army of the North till the end of the war. During the confusion that followed the collapse of the French resistance he was arrested and sentenced to be shot as a Communist, but his mother's letters carried in his pocket saved his life. He graduated M.A., B.Sc.Lond., and took the diploma of M.R.C.S.Eng. in 1876, and the degree of M.D.Basel in 1882. At an early date he turned his attention to medical electricity, remarking, with a characteristic smile, that it was a small subject, all the literature of which could be put on to one shelf in a bookcase. He took to the subject very seriously, and in 1878 published a book, entitled *A Practical Introduction to Medical Electricity*, which reached a second edition in 1884. He did not confine himself to this particular department of therapeutics, but extended his study to neurology generally. *Brain* had been started in 1878 by Sir James Crichton-Browne, Sir John Bucknill, Dr. Hughlings Jackson, and Sir David Ferrier; de Watteville became its editor in 1884. At the end of 1885 the Neurological Society was founded at a meeting held at his house, and with vol. x

(1888) *Brain* became the journal of the society. De Watteville was secretary of the society from 1886 to 1889, and a member of its council from 1890 to 1895, and from 1896 to 1900, when he was succeeded as editor by Dr. Percy Smith, who again was succeeded by Dr. Henry Head in 1905; three years ago Dr. Henry Head gave place to Dr. Gordon Holmes. De Watteville at one time held the post of physician to the electrotherapeutic department, St. Mary's Hospital, and was also physician to the West End Hospital for Nervous Diseases. During his time in London he was a prolific writer; he was a frequent contributor of signed articles to this JOURNAL, and was also a member of the editorial staff. He was a good mountaineer, as became one of his extractions, and among his achievements as a climber was the third ascent of the Great Eiger. He leaves, we understand, two sons, one of whom was a director of the Red Cross bureau for the care of prisoners of war, and after the armistice worked under the League of Nations in repatriating prisoners of war.

Professor ADOLF STRÜMPFEL of Leipzig, the author of a well known textbook of medicine, has died at the age of 71.

Professor EDMOND WEILL, who occupied the chair of children's diseases in the Lyons Faculty of Medicine, has died at the age of 66.

With reference to the late Dr. Wilberforce J. J. Arnold, of whom an obituary notice appeared in our issue of March 7th (p. 486), Dr. F. R. Proctor-Sims, a fellow student, writes: "A quiet, unassuming man, Arnold was nevertheless of great strength of character and of sterling honesty of purpose. His untimely death, coming so soon after he had been made a C.M.G., has deprived his country of a faithful and useful servant, and will be a source of regret to his many friends."

## Medical News.

SIR ARTHUR KEITH, F.R.S., will give a spring course of demonstrations in the museum of the Royal College of Surgeons of England on Fridays, March 20th and 27th and April 3rd, at 5 p.m. on each day. The first will deal with the surgical anatomy of the middle ear, the second with the commoner congenital malformations of the lower limbs, and the third with acromegaly and allied disorders of growth.

THE first Nichols prize of the Royal Society of Medicine has been awarded to Dr. George Gaudes of Heywood, Lancashire, for an essay entitled "The causation, prevention, and treatment of puerperal septicaemia." This prize of £20 is to be awarded every third year, in accordance with the will of the late Dr. Robert Thomas Nichols, for the most valuable contribution towards the discovery of the causes and prevention of death in childbed from septicaemia. Work submitted for the second award should reach the secretary of the Royal Society of Medicine not later than October 1st, 1927, typewritten or printed in English, marked "Nichols Prize," and accompanied by the name and address of the author. Essays previously published may be submitted provided that they were not published before October 1st, 1924.

THE Central Midwives Board for England and Wales met on March 5th, when Sir Francis Champneys was in the chair. It was reported that the representatives of the Ministry of Health on the Board for the ensuing year will be Dr. Marguerite Alice Christian Douglas-Drummond, Miss Edith Greaves, Miss Olive Haydon, and Dr. F. N. Kay Menzies. The chairman paid a tribute of appreciation to Lady Mabelle Egerton, who had worked on the Board for sixteen years, and alluded also to the impending resignation of Miss Paget in terms of warmest recognition of her long and valuable service. It was agreed to proceed with the printing of the Midwives Roll for 1924. Dr. Henry Lewis Barker was approved as lecturer subject to conditions. The next meeting will be held on May 7th.

DURING the past year the work of the Cicely Northcote Trust in connexion with St. Thomas's Hospital has increased considerably in all its branches. The fifteenth annual report covers the year ending October, 1924, and illustrates the many-sided activities of the Trust. The work of the Trust includes the adjustment of financial and other difficulties in connexion with patients, the provision of convalescent treatment, surgical instruments and artificial limbs, the after-care of patients suffering from cancer and other diseases, and a hostel, opened in 1920, for women and girls suffering from

venereal disease. It is possible that fresh ground may be broken in the future, since there appears to be need for the provision of a hostel for mothers and babies on their discharge from the present venereal diseases hostel, so that the mothers could go to work leaving their children under supervision. The income for the year amounted to £3,005, including grants from St. Thomas's Hospital, the Ministry of Health, the payments of patients, and donations. There was a balance of £75 of income over expenditure on the year's working.

DR. OCTAVIUS HALL, late medical officer of health for the County Borough of Plymouth, has been presented on his retirement with a solid silver tea and coffee service, a silver salver and cigarette case, and bound volumes of the reports issued whilst he was medical officer of health for Plymouth and Devonport. Dr. Hall has now been appointed permanent consulting medical officer of health to the borough. The presentation was made on February 26th, when Dr. Hall entertained the staff to dinner, and many tributes were paid to his services to Plymouth.

THE annual meeting of the Mental After-Care Association will be held at the Clothworkers' Hall, Mincing Lane, E.C., on Wednesday, March 18th; the chair will be taken by Sir Charles C. Wakefield, Bt., president of the association, at 3 p.m.

A LECTURE on misplaced teeth will be given by Mr. W. H. Dolamore at the London Hospital Dental School on Tuesday, March 24th, at 5 p.m. Members of the profession and students are invited to attend.

At a meeting of the Royal Sanitary Institute at the Town Hall, Leicester, on Friday, March 27th, a discussion on maternity and child welfare work will be opened at 3.30 p.m. by Dr. Helen Dent and Mrs. C. J. Bond, J.P. This will be followed at 5.30 p.m. by a discussion on smoke abatement. At 8 p.m. Professor H. R. Kenwood, C.M.G., M.B., will give a popular lecture on "Healthy living—facts and fads."

THE Fellowship of Medicine hopes that there will be a large attendance of medical practitioners, whether resident at home or from overseas, to take part in the discussion on post-graduate study in London at No. 1, Wimpole Street, on March 18th, at 6 p.m. Sir Arlthur Lane will preside, and criticism will be welcomed of the present facilities offered through the Fellowship, with suggestions for their improvement. A course at the Brompton Hospital for Consumption and other Diseases of the Chest from March 16th to 28th will have special reference to treatment by artificial pneumothorax; various diseases of the lungs and heart will be dealt with and illustrated clinically. A course in gynaecology at the Chelsea Hospital for Women from March 16th to 28th will include clinical lectures, demonstrations, and the opportunity of witnessing typical operations. An intensive course will be held at the Royal Northern Hospital from March 23rd to April 4th comprising demonstrations, clinics, operations, exhibitions of cases, and formal lectures; application for admission to the course should be made by March 16th. During April courses will be held at the Queen's Hospital for Children, St. Mark's Hospital for Diseases of the Rectum, and the Hampstead General Hospital. A week's course in anaesthetics, beginning about March 23rd, will include practical instruction in throat, nose, dental, abdominal, and nerve anaesthesia; early application is desirable. Further information about these courses may be obtained from the Secretary to the Fellowship, No. 1, Wimpole Street, W.1.

THE annual meeting of Woolcombers, Limited, held at Bradford on March 9th, decided to give £13,000 to the new building fund of the Bradford Royal Infirmary; the contribution will be made in thirteen half-yearly instalments.

RECENTLY a number of metropolitan medical officers of health visited the Oxo factory and witnessed the process of manufacture of Oxo and of the standardization of "oxoid" gland preparations. Any reader who wishes to visit the factory should communicate with Oxo, Limited, Southwark Bridge, S.E.1.

It will be remembered that 300 members of the Inter-State Post-graduate Assembly, directed by the Tri-State District Medical Association, which has some 55,000 members in the United States, are coming to this country next June, when a meeting will be held in London under the presidency of Dr. Charles Mayo. The party will afterwards go on to Manchester, Liverpool, Leeds, Dublin, Belfast, Glasgow, Edinburgh, and Newcastle. We are informed that H.R.H. the Duke of York has consented to accept the honorary membership of the Assembly when it meets in London on June 2nd.

A course in children's diseases has been arranged under the auspices of the Paris Faculty of Medicine, from April 6th to 18th inclusive, at the Hôpital des Enfants Malades, 149, Rue de Sévres, Paris. The subjects include infantile syphilis, endocrine syndromes, mediastinal tuberculosis, and modern conceptions of cerebro-spinal meningitis, rickets, and measles.

THE area of operations of the King's Fund has been extended from a radius of nine miles of Charing Cross to a radius of eleven miles of St. Paul's. Hospitals within this area desiring to participate in the grants made by the Fund for the year 1925 must make application before March 31st to the honorary secretaries of the Fund at 7, Wallbrook, E.C.4. Applications will also be considered from convalescent homes which are situated within the above boundaries or which, being situated outside, take a large proportion of patients from London.

IN July, 1924, a medical research group was formed to make an investigation into the subject of "spiritual healing" in order to prepare and issue a statement on the question. We are informed that the group is holding conferences with representatives selected by the churches and is exploring other avenues of research. The members of the group are: Sir Robert Armstrong-Jones, Dr. Helen Boyle, Dr. H. C. Bristowe, Dr. William Brown, Dr. Charles Buttar, Mr. W. McAdam Eccles, F.R.C.S., Dr. Lottia Fairfield, Dr. E. R. Fothergill (chairman), Dr. J. G. Porter Phillips, Dr. Mary Scharlieb, Sir J. Purser-Stewart, Mr. E. B. Turner, F.R.C.S., Dr. Jano Walker, Dr. Stanley Bousfield (honorary secretary, 10, Albion Street, W.2).

THE Boylston medical prize of Harvard University, including a medal and 500 dollars, is offered for 1925 for the best essay on the results of any original research in medical or chemical science. Essays must be printed or typewritten, and be sent in before December 31st. This prize is open to public competition. Further details may be obtained from the secretary of the Boylston Medical Committee, Dr. Henry A. Christian, Peter Bent Brigham Hospital, Boston, Mass.

THE twelfth Northern Congress of Internal Medicine will be held at Stockholm from August 27th to 29th, when a discussion will be held on the pathogenesis of jaundice and functional diagnosis of the liver, introduced by Dr. E. Menlertgracht of Copenhagen, Dr. O. School of Oslo, and Dr. Tillingreen of Stockholm. Communications intended for the Congress should be sent to the secretary, Dr. Norgaard, Tordenskjoldsgade 3, Copenhagen, before the beginning of April.

THE current issue of the *Prescriber* consists wholly of matter relating to spa treatment, and in particular to the development of British spas. The number is freely illustrated with reproductions of photographs and drawings. It includes a short account of medical hydrology by Dr. R. Fortescue Fox, some notes on old-time bathing practice at Bath, by Mr. John Hatton, and a descriptive list of the spas of Great Britain and Ireland.

DR. S. L. BRIMBLECOMBE, of Stoke-under-Ham, Somerset, has been elected a member of the Somerset County Council.

## Letters, Notes, and Answers.

Communications intended for the current issue should be posted so as to arrive by the first post on Monday or at latest be received not later than Tuesday morning.

THE telephone number of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is Gerard 2630 (Internal Exchange). The telegraphic addresses are:

EDITOR OF THE BRITISH MEDICAL JOURNAL, Aitiology Westrand, London.

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), Articulate Westrand, London.

MEDICAL SECRETARY, Mediscera Westrand, London.

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 4737 Dublin), and of the Scottish Office, 6, Rutland Square, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 4361 Central).

## QUERIES AND ANSWERS.

"OLD OCTOBER" asks for information or advice in the treatment of a boy, aged 6½ years, who has extensive venous plexuses, superficial and deep, situated on the soles of both feet, buttock, perineum, and the under surface of the penis.

### THE TREATMENT OF ASTHMA.

SIR JAMES DUNDAS-GRANT (London) writes that "H. C." (March 7th, p. 488), whose case of asthma has defied "all the usual forms of treatment," has not mentioned whether the nose has been submitted to examination and treatment. If not, he would recommend this in the light of many clinical reports, but particularly of Dixon and Brodie's experiments on reflex contraction of the bronchial muscle excited by stimulation of various sensory areas, described in vol. iv of the *Transactions of the Pathological Society of London*, in a paper on the pathology of asthma. They found the most important reflex from the nasal

mucous membrane, and the upper and posterior part of the nasal septum was the best area from which to produce the reflex. Sources of local irritation—such as hypertrophied middle turbinated bodies, septal deflection, or nasal polyp—should therefore be kept in mind.

Dr. W. F. SOMERVILLE (Glasgow) writes: If "H. C." will make use of high frequency currents, condenser conch, 800 milliamperes, for ten to fifteen minutes daily, and apply the spray fr in the resonator full strength to the back and front of the chest, partially undressed, for another ten minutes, he may be able to afford his patient some relief.

#### INCOME TAX.

##### Purchase of Practice.

"Novus" writes: A, who possesses his own practice, has purchased the practice of B on the terms that he is to hand over to him all proceeds of that practice for two years. Is A liable to income tax on this amount?

\* \* The position seems to be that A has purchased a practice for £x—that is, the two years' receipts. This is a capital sum, and it is not assessable on B, nor is it a deductible expense so far as A is concerned. A is liable to pay income tax on the average earnings of the two practices; he can compute the earnings on the book debt basis if he wishes, either for both practices taken as a whole or for the B practice only if that practice is kept entirely separate from the other; but if he adopts the cash basis, then he must include the whole of the receipts, whether paid to B or not.

##### Outstanding Debts and Depreciation of Equipment.

"C. T. L.," a medical man, started a dental practice on January 1st, 1924, and inquires whether he should or can include in the account of his income for 1924 (1) outstandings—that is, debts due to him, but unpaid, and the accrued proportion of such expenses as rent, rates, etc., and (2) a charge of, say, 10 per cent. in respect of depreciation of the equipment.

\* \* (1) Yes; the full gross earnings are not included unless credit be taken for work completed, but not paid for, and the expenses should also represent a full year's charges. (2) Expenditure on repairs and replacements is admissible, but no allowance can be claimed against professional profits in respect of depreciation. It should perhaps be added that after the first few years—say, four or five—the inspector of taxes will probably agree to accept the accounts on a cash basis, but in the early years of a practice the cash result does not represent the true "income."

##### Travelling Expenses.

"W. H. B." is a full-time medical official and receives a mileage allowance as travelling expenses for the use of his car. Can he claim a deduction in respect of the cost of replacing his car by a new one?

\* \* We think he is not likely to succeed in such a claim. Presumably the assessing authority has in the past made no attempt to ascertain whether his actual "necessary" expenditure has exhausted his allowance or sought to assess any surplus. That being so, it is difficult for "W. H. B." now to raise the point that the allowance has been insufficient—and that is really what his contention amounts to—because of one specific expense of an abnormal kind.

##### Rents from the Irish Free State.

"N." asks for information with regard to the British income tax payable on rents of property in the Irish Free State.

\* \* We are advised that the reason why the Irish tax is not deductible in computing the amount of the assessable income is that that tax is allowed for (in so far as the half taxable rate is concerned) against the tax payable here—in other words, as there is a remedy for the double taxation the tax cannot be treated as an expense. The income is assessable according to the amount "arising" in the previous three years; in our view rents which have been unpaid and forgone should not be regarded as having arisen. The only remedy against the delay on the part of the Irish Free State authorities in dealing with the claim would be to commence legal proceedings in the courts at Dublin; "N." would probably be well advised to continue to exercise patience rather than embark on proceedings which might prove expensive.

#### LETTERS, NOTES, ETC.

##### FOOD PRESERVATIVES.

Dr. G. CLARK TROTTER (M.O.H. Islington) writes to express his concurrence with the hope expressed in the leader on food preservatives, published on March 7th (p. 468), that the regulations will be carried through, and adds: I have not noticed that attention has been drawn to the fact that these draft regulations would appear to be retrograde in one respect (I take restaurants, etc. (see Part 2, section 4, subsection (2), last sentence—"provided that this provision shall not apply where the article of food is sold in any hotel, restaurant, or other such

place for consumption on the premises"). At the present time the sale of preserved cream, if sold for consumption on the premises, requires a notice to be placed in a conspicuous position in the room, or a statement on the bill of fare, or some other adequate means of similar intimation (Milk and Cream Regulations, 1912, section VI). These regulations are, however, to be revoked by section 15 of the proposed new Order. The result is that any food, including cream, may have excessive preservative added. Considering the large number of persons whose work necessitates their taking their meals in restaurants, it would appear that the proposed regulations need some further modification for the protection of the public who use restaurants, in order to prevent excessive quantities of preservative being added to food. If it is desired to make some special provision in the case of res... on... colouring matter or even... should be enacted, and not m... es. A pleasing feature of the regulations is that power is now sought (section V, 2) to get over a difficulty to which I drew attention in 1922, when we found colouring matter being openly sold at the Dairy Show recommended for addition to milk, although the sale of milk with it or any preservative is illegal.

#### TRAFFIC DANGERS.

Dr. FRED. W. HOGARTH (Morecambe) writes: After about the same number of years on the road, during which I have invariably piloted myself, and much of the time spent on the western road to Scotland I have read with interest and appreciation Dr. Charles Buttar's "Traffic dangers and a remedy" (BRITISH MEDICAL JOURNAL, February 21st, p. 380). Although I am rather afraid that the idea has been brought forward in variant forms from time to time, as far as vehicles are concerned, I am unaware of the enunciation of a basic principle... included pedestrians, before this.

Dr. Buttar was undoubtedly found out the chief objection, and, curiously enough, a very strong one—"It is so simple." We are once more nearing Easter, when thousands of motor vehicles, at present laid by, will be brought out for an opening tour. Thousands of beginners will be taking their trial spins also. Easter Monday, when it happens to fall late, is the most dangerous day on the road of all the year, and from about now onwards the pottering genius will be devising fearsome inventions to regale his own little circle of motorists: bright lamps will flash out in the daytime; blood-red letters will suddenly appear at the rear of cars; waving mechanical arms will perform gymnastics to the regular driver's mystification; but there will be nothing simple about any of the "new rules," or what will be learned, and coined, for such, by the great army of fine-weather drivers. Those who draft the Road Bill will be smothered with ideas from this kind of motorist. I have been at the scene of many motor accidents, but I can hardly remember one when some driver of a car or cycle did not propound some entirely new and novel rule of the road. The last accident I was present at was due to some misunderstanding between one car overtaking another, and there was a tremendous smash-up, with dozens of cars and cycles stopped short on their way. While rendering first aid to one of the victims, I was amazed to hear a man, with gauntlets on, say to another, "What if he did wave him on? That only means that the other chap was to pass him—if he could." Only a short time before that accident I was helping an unaccountable motor cyclist into an ambulance. He had whizzed round a corner on his wrong side and run head-on into a stationary landaulette. By this time there were many other cyclists about, and one of them strode up to the only policeman present, who was quite well aware how it happened and had got down lots of particulars in his little book. Pointing to the driver of the landaulette, the cyclist said to the constable, "Look here, have you tested this fellow's brakes? No? Why not? It's your duty in every case like this. They are out of order, I'll bet." So, before the ambulance left, I could see the constable sitting on the front seat while the unhappy driver was running him up and down and wondering what was going to happen next. Is it possible to make any simple rules for large armies of people like this on a crowded road? I can see some of them hugging the wrong side of the road in the hope that they may turn suddenly into the off side of Dr. Buttar's newest car, after the doctor has tried in vain to pass one of these freaks on the proper side.

#### NASAL DIPHTHERIA.

Dr. H. M. EYRES (Richmond, Yorks) writes: Mr. Marsh's note on nasal diphtheria (March 7th, p. 454) suggested to me to send a note of a recent case. A child of 6 was brought to me on February 22nd because of a running nose and poor appetite. Examination of the anterior nares showed only general redness of the mucous membrane. The child was brought again eight days later: there was no improvement; the mucous membrane of one nostril looked grey. A swab was taken and the Klebs-Loeffler bacillus found therein. I visited the child at its home and found that its brother had a patch on one tonsil.

#### VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 33, 40, 41, 44, 45 and 46 of our advertisement columns, and advertisements as to partnerships, assistantships, and locum tenencies at pages 42 and 43. A short summary of vacant posts notified in the advertisement columns appears in the Supplement at page 103.

## A British Medical Association Lecture

ON

## TUMOURS OF THE CEREBRUM.

DELIVERED BEFORE THE NOTTINGHAM DIVISION AND THE  
NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY,  
DECEMBER 3RD, 1924.

BY

H. S. SOUTTAR, C.B.E., M.Ch., F.R.C.S.,  
SURGEON (WITH CARE OF OUT-PATIENTS), LONDON HOSPITAL.

## THE SYMPTOMS OF TUMOURS OF THE CEREBRUM.

THE symptoms of cerebral tumours are so varied in form and so complex in origin that it is difficult to present a view of them which can be compressed into a short space of time. Their effect upon function is as subtle as is the function of the structure in which they grow, but our knowledge of cerebral structure has now advanced so far that we can at least lay down certain principles which may guide us in detecting the existence of an intracranial tumour, and in forming some idea as to its situation, and which may sometimes enable us to define its position with extreme accuracy.

*General Symptoms.*

From time immemorial it has been customary to describe three phenomena—headache, vomiting, and optic neuritis—as the classical symptoms of cerebral tumour. Undoubtedly these phenomena will appear in the great majority of cases if we wait long enough, but they are no more the primary symptoms of cerebral tumour than is acute intestinal obstruction the primary symptom of carcinoma of the colon. They are the symptoms of increased intracranial pressure due, not to the size of the tumour itself, but to a very definite series of events of which the tumour is the cause. The key to these events is to be found in the circulation of the cerebro-spinal fluid.

We now have convincing experimental evidence that the cerebro-spinal fluid is secreted by the choroid plexuses into the ventricular system of the brain. Most of it is produced in the lateral ventricles, from which it pours through the third ventricle, through the narrow aqueduct of Sylvius into the fourth ventricle, and out by the foramina of Luschka and Magendie into the subarachnoid space. It is absorbed into the venous sinuses, apparently by way of the Pacchionian bodies. Anything which obstructs this flow gives rise at once to an internal hydrocephalus and to a high degree of intracranial tension. I have recently had a case under my charge which illustrates this. A woman of 20 was referred to me by Dr. Riddoch with all the evidences of an internal hydrocephalus of long standing but becoming acute. Bilateral decompression failed to give relief, and she died. On examination we found a gross internal hydrocephalus due to the obstruction of the aqueduct by a minute nodule growing downwards from the posterior commissure and blocking its entrance. In dogs a millet seed experimentally placed in the same situation produces on identical effect.

Now any cerebral tumour if left to itself may ultimately produce the same result. If it lies below the tentorium it may produce it at a very early stage by distortion of the pons and mid-brain or by simple pressure. This rise of general intracranial pressure has a curious effect. It drives the cerebellum down into the foramen magnum and down the spinal canal, where it may reach even the third cervical lamina. A "cerebellar cone" is thus formed, beneath which the medulla is compressed as by a wedge, the cardiac and respiratory centres are seriously embarrassed, and the obstruction to the outflow of the cerebro-spinal fluid is further increased. But a tumour lying above the tentorium may in time produce an identical result, though only when it has grown to a very large size. By its gradual encroachment upon the intracranial space it may slowly force the cerebellum down into the spinal canal, and by obstructing the outlets for the cerebro-spinal fluid it may induce a secondary hydrocephalus. If it has developed in a frontal lobe or in some other region of comparative silence, it is quite possible that the first

striking symptoms may be those of secondary hydrocephalus, arising in this way, and the diagnosis of a subtentorial tumour may then be almost irresistible.

The classical symptoms of cerebral tumour are, therefore, those of the late stage, really indicating cerebral obstruction, and it ought to be our aim to diagnose and treat the case before they arise. As this is, however, not always possible it will be well to consider their special characters. The headache is persistent, but with periods of increased severity. It is often worse on waking in the morning, and it is always increased by anything which increases the intracranial pressure, such as exertion or excitement. Vomiting may also take place on rising in the morning, and it has the peculiar character of occurring as a sudden violent act, without cause or warning, which has earned for it the title of "projectile." The fundi may show severe swelling of the discs before the patient is conscious of any visual defect, though a careful examination will usually show some narrowing of the fields for colour or for small white objects. Transient attacks of blindness may occur, but persistent deterioration of vision suggests the onset of atrophy, when complete recovery is impossible.

Among other general symptoms are a certain loss of initiative, mental lassitude and drowsiness, attacks of giddiness, slowing of the pulse, and possibly generalized epileptiform convulsions. A transient diplopia, occurring as it may at a very early stage, should be regarded as a symptom of the very first importance. These are all symptoms of high intracranial tension, and as such they may appear apart from cerebral tumours in such conditions as renal disease, severe anaemia, or lead poisoning. The latter are, however, readily excluded.

*Regional Symptoms.*

It is, however, to the local effects produced by a cerebral tumour that we must direct our attention if we are to diagnose its presence at an early stage and if we are to discover its precise situation. These local effects are not usually the results of destruction of brain tissue, for this only occurs in metastatic carcinoma and sarcoma; nor are they the direct result of pressure upon the nerve cells. They are the result of the interference with the circulation in that particular region of the brain which the growth of the tumour produces, and as such they may appear in two contrasting forms. At first a moderate degree of pressure interferes only with the veins and congestion of the region results, and, as has long been recognized, congestion reveals itself as irritation of which it is the pathological basis. Later a higher degree of pressure will interfere with the arteries, and the resulting anaemia finds its clinical expression in paralysis. As the effect gradually spreads we are likely to have a zone of congestion surrounding a centre of anaemia, and a clinical picture of an advancing irritation leaving paralysis in its wake. Moreover, round any tumour an acute oedema may suddenly arise, with a wide extension of its regional effects and a dangerous increase in the general intracranial pressure.

## THE MOTOR AREA.

The most important part of the cerebral cortex from the surgical standpoint is that which lies immediately in front of the fissure of Rolando—the precentral or ascending frontal convolution. This great fissure, placed almost at the middle of the lateral surface of the hemisphere, might well be described as the watershed of the brain. Behind it the cortex is receptive, in front executive. Behind it lie the post-central convolution for the reception of cutaneous and body sensations, the occipital lobe for the reception of vision, the temporal lobe where sound enters, and the parietal lobe where all these sensations are analysed and gathered together into concrete impressions. In front of the fissure of Rolando lie the precentral convolution, where resides the whole final motor control, the post-frontal area, where memories of combined movements and skilled acts are stored, and the frontal lobe itself, where conduct and initiative reside and which appears to hold the key of all our powers of executive action.

The function of the precentral area appears to be to hold the muscles in just such a state of tone that they may be ready for instant action, and so to transmit demands for

such action that the muscles will respond in a co-ordinate manner. It contains a series of centres which essentially represent simple co-ordinate movements, such as flexion and extension, and these centres are arranged according to a definite plan. At the extreme upper end come the centres for the leg, those for the toes and ankle, the knee and hip are followed by the trunk, and below this come the shoulder, elbow, wrist, fingers, and thumb, in this order. The eyelids, mouth, tongue, and larynx follow; whilst, just in front of the hand area is a special centre devoted to the conjugate movements of eyes and head in rotating to the opposite side. It is usual to describe the fissure as having two genua separating the arm area from the leg area above and the face area below, but a more accurate statement would be that the precentral convolution presents three backward expansions, formed by the development of centres controlling the leg, arm, and face.

The first effect of a tumour pressing upon this region is the production of irritation of those centres around which it produces the most congestion. Periodically this irritation may give rise to a discharge of nervous energy, starting at these centres and spreading to the surrounding cortex. Such a discharge is the basis of an attack of Jacksonian epilepsy, of which it is characteristic that it always starts in the same locality and spreads to other parts of the body in a definite order corresponding precisely to the cortical plan. The fits may be preceded by twitching or tingling in this locality, and they commence with a stage of tonic spasm succeeded by a series of clonic jerks as the cortex becomes exhausted. This exhaustion is further shown in the fact that after a fit there is always very definite weakness in the limb or part of the body in which it started.

As an example of the mode of spread we may cite a case where the fits always started with twitching of the left thumb. After a few moments the tonic stage came on, a tonic spasm spreading successively to the fingers, wrist, and arm, and simultaneously to the left side of the face and tongue, whilst at the same time the head and eyes were spread to the left. Only occasionally did the fits spread to the leg, and they then became general with loss of consciousness.

If, however, a tumour lies deeply beneath the cortex it may produce a paralysis without any of the signs of irritation. Such a paralysis is essentially a paralysis of movement and not of muscles, and it gives rise to postures of a definite type. Thus the arm will tend to take up a position of adduction, with flexed elbow, pronated forearm, and flexed wrist and fingers. The leg, in striking contrast, tends to be strongly extended at the hip, knee, and ankle, with adduction at the hip. In most cases the deep reflexes will be exaggerated and there will be an increase of tone in the muscles which may amount to rigidity.

A tumour pressing on this region may present other features of great interest. Thus, if it is at the upper end of the motor area it may so compress the opposite hemisphere as to produce a paralysis of both legs. If it is low down on the left side it may involve the area of Broca which lies just in front of the foot of the precentral convolution, and the patient may suffer from motor aphasia and lose the power of speech. Again, if it involves the face area, only the lower portion of the opposite side of the face will be paralysed, since the muscles of the forehead and eyelids, usually working together, are activated by impulses from both sides of the brain. An even more remarkable phenomenon is that in a cortical paralysis of the face, though voluntary movement is impossible, emotional movements, controlled by the thalamus, are not

affected, and one may see a patient unable to move his face at will doing so in a perfectly normal manner in laughing at his own efforts. The importance of these phenomena in diagnosing between a lesion of the brain and of the facial nerve is obvious.

Behind the fissure of Rolando lies the post-central convolution, where are grouped centres for sensory reception roughly corresponding in arrangement with the motor centres we have just described. Injury to this area may produce in the corresponding region of the body a loss of postural sense, of localization, of touch, or of the perception of the degrees of heat and cold, and it is of diagnostic import that this loss is irregular in distribution and in the extent to which each element of sensation is affected. Irritation produces a sensation of tingling in the corresponding area, and as these sensory centres are in such close proximity to the motor centres, it follows that a tumour is likely to involve both and that tingling in a limb may be the definite precursor of a Jacksonian convulsion. The following case illustrates certain of these points:

A woman, aged 47, was referred to me by Dr. Riddoch with the history that for four years she had been liable to attacks of cramp in the left leg, occurring as a rule once a month. In an attack twitching behind the left knee was followed by slow forcible flexion at that joint and by plantar flexion of the ankle and toes. This was followed by a dozen violent twitches in the leg, lasting, perhaps, two minutes. The attacks were very painful and were followed by numbness, starting in the left knee, spreading up the leg, and sometimes involving the whole of the left half of the body. The numbness persisted for about an hour. She was a healthy-looking woman with slight weakness of all movements in the left lower limb, increase of the deep reflexes, and an up-going toe.

The upper part of the right motor cortex was exposed and a large rounded tumour was seen springing from the upper part of the dura in this region. The tumour was enucleated and removed with as much of the dura as its base as possible.

FIG. 1.—Localization in the motor area.

I have said that the centres in the precentral area represent simple movements and that their action is the production of that muscular movements require. In front of this area is another, the intermediate precentral area, where these simple movements are compounded into the complex actions required in the execution of skilled acts. Here resides the memory of those subconscious actions, which by long practice we have learnt to accomplish with unconscious skill. These are most highly developed on the left side, and here at its lowest point lies Broca's area, where are stored the motor memories required for speech, whilst a little higher on the left hemisphere may destroy both of these and the patient will be unable to speak or write, although he may be perfectly aware of the words he wishes to use, and may even be able to find them in a dictionary. But apart from injury to the special centres a tumour on either side may induce a subjective feeling of clumsiness, and a mechanic, for example, may find it impossible to carry out manipulations which for years he has executed with ease, although there may be no objective weakness in the arm at all.

Still further forwards we reach the frontal lobe itself, where apparently reside the centres for that more complex combination of actions which we call conduct. A tumour in this region may show its first signs in some alteration in the effect of environment upon action, often in a childish exuberance or an undue sense of well-being and of personal aggrandisement, such as is commonly seen in general paralysis of the insane from atrophy of the cortex in this region. More rarely the result may be fits of unreasoning passion, or an invincible and unreasoning depression. A fine tremor in the ipsilateral hand and a loss of

the superficial reflexes on the opposite side of the body may occur as early localizing signs. Certain of these points are brought out very clearly in the history of a case recently under my charge.

The patient was a man, aged 53, whose wife told us that for some months he had been peculiar and a little irresponsible. Ten weeks before I saw him he had spoken of some clumsiness in the right arm, and he appeared to have difficulty in finding the right words for expression. When he wanted a fork he asked for a biscuit, and he seemed more amused than worried at his mistakes. These symptoms became more marked, when suddenly, after about a month, he lost all power of speech, his right arm became rigid, and his face was drawn to the right. He recovered, but a second attack occurred a few days before I saw him. He was then desperately ill, unable to speak at all or to move his tongue. His right arm was held absolutely rigid, the shoulder adducted, the elbow flexed to a right angle, the forearm pronated. The right side of the face was paralysed, but he could move both legs freely. A diagnosis was made of a deep gliomatous cyst in the lower part of the left frontal lobe. The diagnosis was exactly verified at operation, when 40 c.cm. of fluid was withdrawn from the cyst.

The early history suggested a tumour of a frontal lobe, the attacks placed it on the left side, the rigidity without convulsions suggested that it lay deeply, the involvement of the speech and arm areas, and not that of the leg, placed it low down, and, finally, the sudden onset of acute symptoms, and still more the recovery from one attack, rendered a cystic glioma the most likely diagnosis. It is of interest that two days after decompression and aspiration he talked with freedom and had full control of his right arm.

This case illustrates a point of great moment in the diagnosis of cerebral tumours—the importance of the evolution of the case. It is only by a close study of the gradual development of symptoms, rather than by an elaborate investigation at any one time, that we can hope to arrive at an exact diagnosis. The gradual advance of the tumour may be accompanied by the development of a train of symptoms, sometimes quite transient, which may establish the diagnosis beyond all doubt, though at any one time the symptom complex may be very difficult to unravel. In no case is this more true than in those tumours which, perhaps starting in the more silent regions of the brain, come into contact with the motor paths.

#### THE VISUAL TRACTS.

The tumours of which I have so far spoken have as their chief characteristic some interference with motion. Another group, not perhaps so common but even more fascinating as problems for diagnosis, interferes with vision. Visual impressions starting in the retina pass through the whole length of the brain to the occipital lobe behind. The fibres of the optic nerves decussate in the optic chiasma in such a way that the visual impressions from the visual fields on each side of a median plane are transmitted entirely to the opposite side. Through the optic tracts impulses from the contralateral fields are carried back to the external geniculate body and the pulvinar of the thalamus. From the former run tracts connecting it with the mid-brain and with the centres which control the movements of the eyes. From the latter spread out the optic radiations, looping round the descending horn of the lateral ventricle to reach their destination in the cortex of the occipital lobe. It is to this final portion of the optic path that I would for a moment direct your attention.

The optic radiations are so arranged that the upper fibres receive impulses from the upper portions of the retinae, the lower from the lower. This order they maintain right up to the point when they terminate in the cortex above and below the calcarine fissure on the mesial aspect of the occipital lobe. In relation to tumours of the occipital lobe itself this distinction is not of importance, for as a rule the whole visual area is involved, with result-

ing disturbances of vision in the contralateral visual field. These disturbances may be of two kinds—irritative or paralytic. The former are more likely to be produced by cortical tumours, and appear as flashes of light, often coloured and suggesting fireworks. Probably the fortification lines of migraine are due to vascular disturbance in this region. Deep tumours, on the other hand, produce a gradual contraction of the visual field on the opposite side, best shown by testing with small objects, white or coloured. The superficial tumours again tend to spread forwards over the cortex and to involve the lower sensorimotor areas, producing numbness in the opposite face or hand. The deep tumours tend to involve the posterior part of the internal capsule, producing sensory changes in the opposite half of the body and paresis in the opposite leg.

But to the optic radiations themselves we owe a syndrome as beautiful as any in cerebral pathology, and in the hands of Cushing they have supplied the key to what was one of the most obscure regions of the brain. These radiations as they leave the optic thalamus wind forwards, outwards, and finally backwards round the descending horn of the lateral ventricle, occupying as they do so the posterior part of the temporal lobe. Their arrangement in upper and lower groups connected with the upper and lower portions of the retinae has already been noted. A tumour, then, in the

lower part of the right temporal lobe will involve those fibres which carry impulses from the opposite upper visual field, and the left upper quadrant will be blind, and we have the condition known as a left upper quadrant homonymous hemianopia. The discovery of these quadrant hemianopias has revolutionized localization in the temporal lobes.

It is typical of quadrant hemianopias that the visual defect is incomplete, and it is owing to this fact that they have so long escaped attention. They can only be discovered by the most accurate and painstaking perimetry, and only at an early stage of the develop-

ment of the tumour. A rough perimetry will miss them entirely, and in a late stage they will be merged in a complete hemianopia, but if found they are almost conclusive evidence of a tumour in the temporal lobe.

But the temporal lobe yields another symptom as bizarre as any in cerebral symptomatology. When a tumour involves the uncus the patient is liable to peculiar attacks lasting for a few seconds and perhaps recurring many times in the day. In these he is overpowered by a dreamy sensation, the world seems remote, and voices sound far away. In this state he may have curious hallucinations of smell, taste, hearing, or vision. The first two are perhaps the most common, and though sometimes pleasant are usually so repulsive as to produce an expression of disgust on the face. Those of vision are very curious and form definite pictures, such as a row of black cats or a little figure, in contrast to the visual disturbances seen in tumours of the occipital lobe. These pictures are the same on every occasion, and they are always in the blind portion of the visual field. The combination of a quadrant hemianopia with uncinate attacks thus forms a very complete and exact syndrome, distinguishing sharply when it occurs tumours of the temporal lobe.

#### THE POSSIBILITY OF SURGICAL RELIEF.

We see, then, that those tumours of the cerebrum which are accessible to surgery give rise in many instances to symptoms characteristic of their locality, though when the case is actually seen these are only too often masked by those of general intracranial pressure. It will be worth while to consider for a moment which of these tumours may be amenable to surgical treatment.

FIG. 2.—The course of the visual tracts.

The commonest tumour of the cerebrum is a glioma and its removal is impossible. The relief which may be obtained by decompression is, however, sometimes very considerable, and of this the following case furnishes an example.

A woman, aged 38, was sent to me with a history of severe frontal headaches extending over six years. A year before I saw her she suddenly fell down unconscious and had a series of violent convulsive attacks starting in the left arm. From this she recovered completely. It had for some time been noticed that she was somewhat unstable mentally, acting with excitable levity. She occasionally had a tremor in the right arm and leg, and vision was failing.

She was an excitable woman in abnormally high spirits. She had severe papilloedema, most marked on the right, but no changes in motion, sensation, or reflexes were discovered. A deep glioma of the right frontal region was diagnosed, and a large decompression in this region was performed, the brain being under very high pressure. She recovered completely, her headaches disappeared, and she regained her normal health and vision; even the fundi became normal. For eighteen months she remained in excellent health, though a left hemiparesis and an enormous hernia very gradually developed. She then quite rapidly became comatose and died.

Although a glioma cannot be removed it may degenerate in the centre and become cystic, and in such a case it is sometimes possible by aspiration of the cyst to give considerable relief to the patient. If the cyst is at all superficial and can be treated with formalin the relief may extend over a considerable period; in some of these cases the introduction of radium has given good results. In such cases a decompression not only relieves the pressure but enables the cyst to be aspirated with facility. The following is an example:

A man, aged 44, was referred to me by Dr. Riddoch with the story that six months previously he had had a sudden attack of giddiness, followed by pains in the back of the neck and difficulty in speaking, which lasted for a few minutes. Since then he had had a few similar attacks, and six weeks before I saw him, after one of these, the right arm began to shake and the right side of the face to twitch. When this had passed off the arm remained weak and the difficulty in speech persisted. He was an intelligent man with marked apraxia and aphasia. There was slight weakness of the right side of the face and tongue, and spastic paresis of the right arm and leg with increase in the deep reflexes. He rapidly became worse, complete right hemiplegia developed, he was unable to move his tongue, and had increasing difficulty in swallowing. He became very drowsy and the respirations stertorous. Left temporal decompression was performed and a large cyst discovered lying deeply in the left frontal lobe, from which 44 c.cm. of turbid fluid was withdrawn. He made a remarkable recovery. His speech commenced to return in four days and he regained full power in his limbs.

The only removable tumours which are at all common in the region of the cerebral hemispheres are the endo-theliomata. These arise from the inner surface of the dura, probably from the lacunae of the anterior longitudinal sinus. Sometimes they are firm, rounded, fibrous tumours, often, however, with central degeneration; sometimes they are soft and diffuent. They may have a pedicle or they may be sessile on the inner surface of the dura. The bone over them is very vascular, and they have a curious power of stimulating its growth, so that external bony tumours may appear on the skull. They may, indeed, invade the bone, with which they thus become indissolubly connected, but in no circumstances do they invade the brain; they press into its substance, and their removal may at first leave a large cavity, but in a few moments the brain returns to its normal position and the cavity is entirely obliterated.

Theoretically these tumours should be completely removable and should never recur, but it is not always possible to obtain this result. In the soft type the tumour may break up so far that there can be no certainty of its complete removal, and in the sessile variety its connexions with the superior longitudinal sinus may be so complete that only a resection of the sinus, with the grave risks which that involves, could ensure total ablation. One case of the latter condition has already been mentioned, and of the former the following is an example:

In October, 1921, I operated upon a woman, aged 25, who for eighteen months had suffered from morning headaches of increasing severity, and latterly accompanied by vomiting. She had had attacks of tingling and numbness in the fingers of the left hand, spreading to the shoulders and to the left side of the tongue, and loss of sense of position in the fingers of the left hand.

The right Rolandic area was exposed by an osteoplastic flap, and a large, soft, purplish tumour was found arising from the inner surface of the dura over the middle of the right Rolandic area.

On opening the dura a mass of diffuent material about the size of a tennis ball oozed out, the cavity in the brain being almost instantly obliterated. The dura was removed as widely as was practicable and the osteoplastic flap was closed. She made an uninterrupted and complete recovery.

In April, 1924, after three and a half years of perfect health, she suddenly had a succession of violent fits, starting with tingling in the left fingers, but becoming general, and accompanied by loss of consciousness. The papilloedema, which had entirely disappeared, was found to have returned. Exploration showed masses of soft growth protruding through the old trephine holes in the bone, which was itself widely invaded by soft vascular growth. The bone was widely resected and the growth removed as completely as was possible, although it extended up to the middle line. She again recovered completely, and so far has remained in perfect health. It is possible that the use of x rays over the large opening left in the skull may enable us to prevent further recurrence.

It will thus be seen that although only in a very limited number of cases can we expect to effect a complete cure by surgical interference, there are many in which we can give considerable relief. The most important factors in success are early diagnosis and precise localization; both should be effected before general symptoms have developed and before an increased intracranial pressure has added to the difficulties and dangers of an operation. There is no field of surgery in which so much depends upon the close co-operation of the physician and the surgeon, upon the enterprise of the former and the restraint of the latter.

## An Address

ON

## MASSIVE PULMONARY COLLAPSE.\*

BY

A. BERTRAM SOLTAU, C.M.G., C.B.E., M.D.,

M.R.C.P., F.R.C.S., K.H.P.,

PHYSICIAN, SOUTH DEVON AND EAST CORNWALL HOSPITAL, PLYMOUTH.

It might be supposed that the subject of pulmonary collapse is largely of academic interest, but the clinical manifestations are of great importance, both to the physician and to the surgeon, and a prompt recognition of the physical signs and the symptoms, and where possible their prevention or their rectification, is therefore of great value.

### PHYSIOLOGICAL INTRODUCTION.

Before proceeding to discuss the causation of pulmonary collapse a brief recapitulation of the essential anatomical and physiological facts of respiration may be helpful. It is customary to regard the lung as a single organ, expanding as a whole, and to disregard a possible significance of its division into lobes. Keith<sup>1</sup> has, however, shown that the great fissure is of fundamental importance, in that it separates the lung into areas, the method of expansion of which is, distinct, the upper lobe being expanded by the mechanism of the upper ribs, and the lower lobe by a compound mechanism formed by the diaphragm and lower ribs. Further, the extensibility of the lung is not uniform in degree, but varies with the three anatomical zones into which it is divided. These are (a) the root, practically non-extensible; (b) the intermediate zone, containing vascular and bronchial ramifications with some extensible tissue between; and (c) the outer zone, consisting entirely of expansile tissue. Expansion takes place by the moving apart of the rays of the inextensible structures, and the filling out of the intermediate and outer expansile areas, a mechanism which Keith has likened to the opening of a Japanese fan.

It is impossible here to enter into any detail of the muscular mechanism brought into play in respiration, and a somewhat dogmatic outline must suffice.

The upper part of the thoracic cavity is conical in shape, the lid being formed by the first ribs and the manubrium sterni. This lid is held immobile by the sealeni, and acts as the fixed point from which the upward movement of the ribs originates. In the main the expansion of the upper lobe is brought about by the lifting of the five upper ribs, with an increase in the antero-posterior thoracic diameter, owing to the axis of rotation of these ribs being set almost at right angles to a vertical section. Each successive rib

\* Delivered before the Plymouth Medical Society.

moves through a rather wider space than the one above; hence the undulating expansion described by Hoover.<sup>2</sup> The lifting of the ribs is the result of contraction of the external intercostals. The contraction of the diaphragm has a very slight expansile effect on the upper lobe, for the crura, being attached to the root of the lung through the pericardium, will on contraction displace the pulmonary hilus downwards, and so help the ventilation of the apex.

The lower part of the thorax from the fifth rib downwards is cylindrical in form, and for its expansion depends in part on the intercostals and in part on the diaphragm. The external intercostals carry on the same lifting process as already described, but with the alteration of the axis of rotation of the ribs, the angle with the vertical mid-plane becoming progressively more acute, the resultant movement is rather in a lateral than in an antero-posterior direction.

The contraction of the diaphragm is the other great factor in the ventilation of the lower lobes. Attached behind to the lumbar vertebrae, laterally to the lower edges of the six lower ribs, and in front to the ensiform cartilage, the fibres converge to their insertion in the central tendon. At rest two domes are formed below the bases of the lungs, the outer wall of each being in contact with the parietal walls. Contraction shortens the fibres, flattens the domes, and by so increasing the vertical diameter of the thorax permits the lungs to descend and expand. The diaphragm and the intercostals are in opposition in their pull on the lower ribs, for the former tends to close the subcostal angle and the latter to open it. The flatter the dome of the diaphragm the more direct is the pull it can exert, and the more force it will bring into play on the costal margin (Hoover<sup>2</sup>). This point is of considerable clinical importance. Depression of a diaphragmatic dome, either by pleural effusion or cardiac enlargement, will increase its mechanical efficacy, and this is shown by a reduction in the subcostal angle, instead of its increase as in normal respiration, in which the outward pull of the intercostals can overcome the inward pull of the diaphragm (Macleod<sup>3</sup>). A very critical study by Sir Charlton Briscoe,<sup>4</sup> in his Arris and Gale Lectures, of the action of the diaphragm will repay close study by those interested in this subject. He differentiates the contraction of the diaphragm into two parts—the crural, dependent solely on the phrenic nerves for stimuli, and the costal, which obtains part of its nerve supply from the intercostal nerves. He has further classified patients into three types, according to their manner of breathing. The A type depends almost entirely on the crural contractions for diaphragmatic respiration. In the C type, at the other extreme, the costal contractions are the more prominent. The adoption of the supine position will materially affect diaphragmatic respiration, and this has, as will be seen later, a profound influence on the production of collapse.

#### THE CAUSATION OF PULMONARY COLLAPSE.

It is to William Pasteur that the credit is due for first noting and describing the phenomena which he described as "post-operative massive collapse of the lung," in 1908.<sup>5</sup> Several other communications by him followed, and he gave a general review of the subject in 1911.<sup>6</sup> It was not, however, until the war led to a concentrated study of chest wounds that collapse came to be recognized as a frequent occurrence, for explanation had to be found for the many cases in which signs were present which could not be attributed to any of the generally accepted pathological conditions. In all the published writings on gunshot wounds of the chest references will be found to pulmonary collapse (Harrington,<sup>7</sup> Soltau and Alexander,<sup>8</sup> Gask and Wilkinson,<sup>9</sup> J. R. Bradford,<sup>10</sup> Soltau,<sup>11</sup> Bradford<sup>12</sup>).

It is obvious that the collapse of a lung, in whole or in part, may be brought about by various causes. A complete obstruction of the main bronchus, as occasionally occurs from inhaling a foreign body, must inevitably lead to such a condition, and this fact led to the theory that collapse was caused by the accumulation of bronchial secretion to such an extent as to plug the bronchi (Elliot and Dingley<sup>13</sup>). Such a condition, however, has not been commonly found in *post-mortem* examinations. Moreover, in many cases a lung has been profoundly collapsed during

life without the patient having any expectoration or other sign of increased bronchial secretion. Cases of purulent bronchitis with great excess of secretion do not appear ever to develop a massive collapse, though small collapsed areas may be seen *post mortem*. The collection of secretion cannot therefore be accepted as a complete explanation, though in some cases it may play a small contributory part.

Pasteur himself regarded the condition as being due to diaphragmatic paralysis, and there is increasing evidence that inhibition of the activity of that muscle forms an essential part of the process of collapse. X-ray examination of these cases invariably shows that the diaphragm on the affected side is raised, often to a higher level than that reached in the extreme expiratory position. It has even been seen to move in the reverse direction, rising with inspiration owing to the increase of intra-abdominal pressure from the descent of the unaffected lobe. Moreover, frequent opportunity was afforded during the war of observing the diaphragm through a hole in the chest wall—from wounds or on the operating table—and the flaccid, atonic condition of the muscle was obvious.

It is not so easy to determine why the diaphragm is paralysed, and this question is still under debate. The present writer, with Dr. Alexander,<sup>8</sup> advanced the view that it was a reflex paralysis, the afferent impulses being conveyed to the respiratory centre from the focus of irritation by means of the vagus, and the efferent by the phrenics. They pointed out that collapse was not of necessity associated with injury to the lung or to the thoracic wall, but might occur, as Pasteur had originally noted, after abdominal injuries quite remote from the diaphragmatic region. A penetrating wound of the pelvis, for instance, exhibited a very typical picture of pulmonary collapse. In military experience certainly by far the greater number of cases were directly associated with injuries, not necessarily penetrating, of the chest wall or lung. In civil experience the majority of cases are a direct sequel to abdominal operations, particularly those on the upper abdomen. In the writer's experience operations involving the liver and bile passages are especially likely to be followed by collapse of the lung.

Briscoe<sup>4</sup> advances an alternative view as to the origin of the paralysis, regarding it as merely an exaggeration of the respiratory changes which take place when the supine position is adopted. In this position the costal type of diaphragmatic respiration is largely suspended, particularly in those patients of type A whose respiration is mainly crural in origin. Subsequent irritation of the crura or of their pleural covering will lead to inhibition of the crural respiration, and hence to paralysis and complete deflation. Further observation is needed to determine the relative importance of these two views. Whatever the actual mechanism which inhibits the diaphragm, the result is a cessation of ventilation of the lung, with speedy absorption of the residual alveolar air, and so complete collapse. Falconer<sup>14</sup> supports Briscoe's view and records the comparatively frequent occurrence of massive collapse in prolonged malarial cases. He was inclined to regard the condition as being caused by perisplenitis. Watson and Meighan<sup>15</sup> have recorded cases of diaphragmatic paralysis which they attributed to a functional disturbance of the phrenic centre. It would be interesting to know whether any observations have been made in the cases, recently described, of very rapid breathing as a sequel to encephalitis lethargica, to note the condition of the diaphragm.

Whilst the study of pulmonary collapse from injury was being studied a further very interesting fact came to light—namely, that the uninjured lung may frequently share in the condition, a phenomenon to which the term "contralateral collapse" was applied. This condition has been seen both with penetrating and non-penetrating wounds of the chest. The radiograms exhibited, taken by Captain Donaldson, show an extreme degree of massive collapse of the right lung, resulting from a severe blow to the left thoracic parietal wall. The writer recently saw a similar case in which the shaft of a cart had inflicted a heavy blow on the left side, and the right lobe was collapsed. Curl<sup>16</sup> has described in some detail the contra-

lateral signs associated with chest wounds. These cases of contralateral collapse are difficult to explain without assuming a nervous reflex.

Finally, the well known experience of being "winded" by a sudden blow may be due to temporary paralysis of the diaphragm. Here the immediate onset must preclude any inflammatory cause. The happy conjunction of an x-ray plaut and a "winded" patient may settle the point.

#### VARIETIES OF COLLAPSE.

The most common condition to find is massive collapse involving the whole of the lower lobe. More rarely the whole of the lung may be involved, and very occasionally the upper lobe alone is affected. In cases where a part only of the lower lobe is collapsed a wedge-shaped area with the base downwards will be found, giving the characteristic signs. Collapse may be homolateral, or, in cases of injury, contralateral. In civil practice collapse following surgical operations most commonly affects one base only, but it may be bilateral, each side becoming involved successively or simultaneously.

#### PHYSICAL SIGNS.

These are not unequivocal, and some practice is required to make certain of the diagnosis, for in many respects there is a close resemblance to the physical signs of pneumonia. Observation is of the greatest help, for the retracted immobile chest wall affords a striking contrast to that of pneumonia, in which with immobility the appearance of fullness is so frequently noticeable. The difference in the ribs in the two cases may be compared to the appearance of a concertina when closed and when extended.

Palpation is the critical diagnostic test, for by that means the position of the apex beat may be determined. The most definite and constant sign of collapse is displacement of the apex, and this always takes place towards the collapsed area. The displacement may be extreme, the apex being found well over towards the axilla, and frequently lying at a higher level than the normal.

This alteration may take place with great rapidity, the apex having been found to have moved two inches in the course of a few hours. On percussing the chest a marked alteration in the note will be elicited. With complete collapse there is absolute dullness, so definite as to suggest the presence of fluid. The position of the apex beat, however, at once eliminates the possibility of effusion. On the left side the increase upwards of the gastric resonance will indicate the high level of the diaphragm, and so suggest paralysis of that muscle. The auscultatory sounds may vary very greatly, being modified both by the degree of collapse present and with the phases through which the condition passes.

In a typical case followed from its commencement, at first breath sounds are practically absent, or only the faintest respiratory "whisper" will be heard. This absence of breath sounds is accompanied by absence of vocal resonance. We are listening to a "dead" lung through which no bronchial air is passing. The sign-complex is therefore a retracted immobile chest with raised diaphragm, dull on percussion, and exhibiting neither breath sounds nor vocal resonance, and with the heart displaced towards the dullness. In the second stage there is a dramatic alteration. The percussion note is still dull, but the breath sounds are tubular or amphoric, and vocal resonance is greatly increased. Ventilation is commencing and the bronchial respiration becomes audible.

The clinical picture resembles a pneumonic consolidation, except for the shape of the chest and the position of the apex. In the final stage dullness becomes less pronounced, the tubular breath sounds are less definite, and frequently moist adventitious sounds are present. Air is commencing to enter the alveoli and a certain excess of secretion may be present. With the expansion of the lung the heart returns gradually to its normal position. This phase is frequently confused with bronchitis, and probably not a few of the cases of so-called post-anaesthetic bronchitis are really in the final stage of massive collapse. Pyrexia is not uncommon, but does not reach a high degree. It is to be

expected that a bronchial infection will frequently complicate collapse, and even a true pneumonic consolidation may occur in the collapsed lung.

#### SYMPTOMS.

Massive collapse with unmistakable physical signs may produce very few symptoms. A certain degree of dyspnoea, more marked on exertion, is usually present, and is, of course, much more pronounced if both lungs are involved. Cyanosis is not a marked feature, for the unaffected lung area is ample to secure sufficient oxygenation whilst the patient is at rest. The writer has, however, not infrequently noticed that the colour of the face is a brick red, and has on more than one occasion ventured a diagnosis of collapse based on this appearance, and has found it confirmed on further examination. The absence of cyanosis may be explained by Haldane's<sup>16</sup> reasoning, that where a lung, by consolidation or collapse, has ceased to have any pulmonary circulation, only the bronchial persisting, the whole of the venous blood is oxygenated in the unaffected areas. Where, however, the pulmonary circulation is partially open, venous blood will circulate through lung area which is not capable of oxygenating it, and therefore a mixed stream of oxygenated and non-oxygenated blood will reach the systemic circulation, causing cyanosis.

Cough of a weak, irritating type is frequently present. It is not usually productive—in part owing to lack of pressure from behind, as the diaphragm is out of action, and in part also because secretion is not necessarily increased.

#### DIAGNOSIS.

The diagnostic signs have been detailed already, and it is only necessary to refer very briefly to the main points. The appearance of the chest and the position of the apex beat are the two cardinal signs to which attention should be directed. If these be remembered, confusion with either pleural effusion, pneumonia, or bronchitis will not arise. In military practice the presence of a coexisting haemothorax introduced disturbing signs, which will practically never arise in civil practice. It should not be forgotten, however, that a pneumonic consolidation is not unknown in a collapsed lung, more particularly as reinflation is commencing. So, also, an infective bronchitis may be associated with collapse. It is hardly necessary to refer to the great assistance in diagnosis which x-ray examination gives, and in cases of doubt this assistance should, where possible, be sought.

#### TREATMENT.

It is obvious that very little can be done in the way of active treatment. In cases in which dyspnoea is a symptom oxygen is essential. This should be given practically continuously in measured quantities, by means of a Haldane oxygen apparatus. In cases requiring prolonged or exhausting dressings oxygen should be given as a routine during the dressings. The importance of Sir Charlton Briscoe's investigation lies in the fact that the supine position favours collapse. To the surgeon the value of placing his patient as soon as possible in the semi-upright position will appeal. It is hardly too much to say that all operations on the upper abdomen should be nursed in this position, as soon as post-operative shock has passed off. Nursing homes still are frequently ill provided with comfortable and easy means of raising patients into this position and maintaining them there. The Fowler frame, introduced during the war into casualty clearing stations, was an admirable and simple mechanical device for attaining this end.

The object of this communication is to call attention to a condition which occurs far more frequently than is supposed, and which has not received much attention in the general medical press.

#### SUMMARY.

1. Massive pulmonary collapse is a definite clinical condition.
2. It is caused by inhibition of the diaphragmatic action, whether from reflex or inflammatory causes.
3. Its onset is favoured by the supine position.

4. It follows direct trauma of the chest wall or lung, and surgical operations on the abdomen, even remote from the diaphragm.

5. It gives definite physical signs, which may simulate pneumonia or pleural effusion.

6. The differential diagnosis depends on determining the position of the apex beat and the diaphragm.

7. It may, in cases of injury, affect the lung on the side remote from the trauma.

8. Its occurrence, whilst of itself not necessarily of grave import, yet places another burden on a patient already struggling with injury or disease.

9. Treatment should be preventive.

## ON THE POSSIBILITY OF RESTORING MOVEMENT TO A PARALYSED VOCAL CORD BY NERVE ANASTOMOSIS.\*

(An Experimental Inquiry.)

BY

LIONEL COLLEDGE, M.B., F.R.C.S.,

SURGEON, EAR AND THROAT DEPARTMENT, ST. GEORGE'S HOSPITAL.

THE following series of experiments were carried out by Sir Charles Ballance with the collaboration of the writer. The experiments were performed at the National Institute for Medical Research, Hampstead, and were made possible by the facilities granted by the Medical Research Council. Although final conclusions have not been reached, certain definite results have been obtained, and it is at the suggestion of Sir Charles Ballance that this description of the research has been written.

Experiments on the effects of an anastomosis of the recurrent laryngeal with another nerve by previous observers do not appear to have given very definite results, probably owing to the difficulty of accurate observations on the movements of the vocal cords in animals without killing them at the end of the experiment. This is now easily overcome by using a direct vision laryngoscope. The larynx of a monkey and the movements of the vocal cords can be not only seen but carefully studied through the spatula of Chevalier Jackson, employing the model designed for the child. Direct observation has therefore taken the place of inferences drawn from the presence or absence of such symptoms as stridor, hoarseness, or roaring in animals. It has even been possible, although certain technical difficulties had first to be overcome, to record the movements of the vocal cords on a cinematograph film.

The results of the experiments may be divided into three groups.

### I.—ANASTOMOSIS WITH THE VAGUS.

The first nerve employed was the vagus. Chevalier Jackson, in his book on endoscopy, suggests that an anastomosis between the vagus and the recurrent laryngeal might cure paralysis of a vocal cord. Since the recurrent laryngeal nerve passes down the neck in the trunk of the vagus, such an anastomosis would be most likely to succeed if the cut end of the recurrent laryngeal were united to that part of the vagus which contains the fibres of the recurrent laryngeal, before they have left the main trunk. There is, however, no means of distinguishing the fibres of the recurrent laryngeal from the rest of those which form the trunk of the vagus, so that there would be only a small chance of effecting such a reunion.

\* An illustrated article by Sir Charles Ballance on experiments in which the facial and recurrent laryngeal nerves were anastomosed with other nerves was published in the *JOURNAL* (1924, vol. ii, p. 349).

Actually the end of the recurrent laryngeal was implanted into the side of the vagus in two goats, a rhesus monkey, and a baboon; but the last animal died of pneumonia three weeks later, which suggests that the operation may not be devoid of risk. There were therefore three effective experiments in this group.

In a large male goat the vagus was nearly half divided and the cut recurrent laryngeal sutured to the proximal lip of the incision. At the end of ten months no movement of the vocal cord had been observed, though it appeared to have become straight and tense. This effect, however, may have been produced by contracture of the intrinsic muscles of the larynx rather than by the return of the muscular tone. On exposing the anastomosis the recurrent laryngeal was found kinked and involved in scar tissue, nor was any movement of the cord produced by stimulation of the trunk of the vagus, the anastomosis, or the recurrent laryngeal itself. The experiment repeated on a young goat gave negative results at the end of six months.

In the rhesus monkey the same operation was done and the corresponding vocal cord was seen to be paralysed. At the end of four months no movement had returned though the cord was more tense. The anastomosis was exposed at the end of seven months, and abduction of the paralysed cord was obtained by stimulation (a) of the trunk of the vagus, (b) the site of the anastomosis, and (c) the recurrent laryngeal nerve.

The excursions of the cord were not quite so wide as on the sound side.

It appeared, therefore, that the muscles were innervated from the vagus, although no spontaneous movement occurred, and Professor Starling suggested that if the animal were partially asphyxiated the forced inspiration so produced might be so powerful that the muscles would receive a strong enough nervous impulse to cause a contraction. This experiment was tried at the end of nine months, and the cord was seen to abduct several times, though not so widely as on the opposite side. The same effect was seen at the end of twelve months, but was less after fifteen months, and has disappeared after seventeen months, and still has not reappeared.

It may be concluded from these experiments that, although a nervous connexion may be re-established by a recurrent laryngeal vagus anastomosis, it is useless to expect return of spontaneous movement in the corresponding vocal cord.

### II.—ANASTOMOSIS WITH THE DESCENDENS NONI.

In another series of experiments the recurrent laryngeal nerve was anastomosed end-to-end with the descendens noni. This operation was done on four rhesus monkeys.

In the first experiment the recurrent laryngeal was anastomosed end-to-end with the descendens noni and the distal end of the descendens noni implanted into the side of the hypoglossal. Before the suture was completed it was observed that stimulation of the distal end of the recurrent laryngeal caused abduction of the cord. This animal died from bites received from another monkey six weeks after the operation, so that no result was obtained.

In the second experiment the same operation was done on the right side, except that the distal end of the descendens noni being very small was left free. At the end of two months there appeared to be increased tension in the cord but no spontaneous movement. Stimulation of (a) the hypoglossal proximal to the origin of the descendens noni, (b) the descendens noni, (c) the anastomosis, all caused abduction of the cord, showing that a nervous impulse could pass through the anastomosis. At the end of four months there was still no spontaneous movement in the cord, but on partial asphyxiation abduction of both cords followed but soon ceased. At the end of five months, and again at the end of seven months, there was still no movement of the cord on tranquil respiration, but wide excursions of both cords followed partial asphyxiation and lasted for two minutes. The movements of the right cord gradually ceased as the effects of the asphyxiation passed away. The animal became ill at the end of nine months and was killed, but it was noted that still there were no spontaneous movements of the right cord.

In the third experiment the animal had to be killed at the end of seven months; the results were exactly the same as in the second experiment.

In the fourth experiment the descendens noni was anastomosed end-to-end with the recurrent laryngeal. The distal end of the descendens was implanted into the side of the phrenic. No spontaneous movement returned to the vocal cord, but when the animal was killed at the end of three months stimulation of (a) the hypoglossal proximal to origin of the descendens noni, (b) the descendens noni, and (c) the anastomosis, all caused abduction of the vocal cord.

The results of these experiments with the descendens noni show that, as in an anastomosis with the vagus, the muscles controlling the movements of the vocal cord become innervated, but no movement occurs in the cord because the appropriate impulse does not pass along this route.

It is probable that when the animal swallowed, an associated movement of the vocal cord occurred, for at that moment an impulse would be travelling down the descendens noni, but no means of making this observation satisfactorily could be devised.

Dr. Frazier of Philadelphia,<sup>1</sup> at the request of Dr. Chevalier Jackson, performed an anastomosis between the recurrent laryngeal and the descendens noni in two patients with vocal cord paralysis. The results of these operations were the same as those on the monkeys. Tension returned to the paralysed cord, but no spontaneous movement. Descendens noni-recurrent laryngeal anastomosis is therefore useless for the relief of paralysis of the vocal cord.

### III.—ANASTOMOSIS WITH THE PHRENIC.

It appeared that if the vocal cord could be linked up with the muscles of respiration, then a rhythmical impulse rightly timed would pass through the anastomosis and might restore the normal movements of quiet respiration to the cord. In this case, in contrast to the dissociated movement required for the cure of facial palsy, an associated movement with the respiratory muscles would be desirable.

In the third series of experiments, therefore, the recurrent laryngeal was anastomosed to the phrenic to obtain associated movement between the vocal cord and the corresponding half of the diaphragm. In this series six experiments were performed on three baboons, a hussar monkey, and a rhesus. In one baboon, which died at the end of the fourth month, the recurrent laryngeal was implanted into the side of the phrenic, which apparently had only one root coming from the fourth cervical nerve. In another, which died at the end of a month, the recurrent laryngeal was anastomosed end-to-end with the root of the phrenic arising from the fourth cervical nerve. In neither case had any movement been restored to the cord when the animal had to be killed.

There remained, therefore, four effective experiments.

The first experiment was performed on a baboon. The right recurrent laryngeal was anastomosed end-to-end with the phrenic, and, with the object of restoring the movements to the diaphragm, the distal end of the phrenic was united to the central end of the descendens noni, and the distal end of the descendens noni implanted into the side of the hypoglossal. Stimulation of the recurrent laryngeal during the experiment caused abduction of the paralysed cord, and of the phrenic caused contraction of the diaphragm. At the end of two and a half months no movement was observed in the right vocal cord. At the end of four months the vocal cords were observed to move equally during quiet respiration. The adductor spasm caused by partial asphyxiation was followed by abduction of both cords, but the abduction was a little greater on the left (normal) side than the right.

At the end of six months the cords moved symmetrically, but the excursions of the right cord were now wider than those of the left (normal) cord. At this time the left recurrent laryngeal was anastomosed end-to-end with the left phrenic, thus paralysing the left vocal cord, whilst the right continued to act through the right phrenic. At the present time slight abduction can be observed in the left cord, but, probably owing to some injury to the neck during the administration of an anaesthetic, the right cord has again become paralysed.

These two experiments, however, show that anastomosis with the phrenic is capable of reproducing the normal movements of the vocal cords in tranquil respiration.

In a hussar monkey the phrenic was exposed and separated into two bundles, one of which was divided and anastomosed end-to-end with the distal end of the recurrent laryngeal. This animal shows only the slightest movement of abduction after ten months, and even this disappears altogether under a deep anaesthetic. On partial asphyxiation, however, adductor spasm of both cords occurs.

In a rhesus monkey the distal end of the right recurrent laryngeal was implanted into the side of the phrenic. At the end of two months the right cord was still paralysed, but it appeared to have become more tense than immediately after the operation. At the end of three months there was still no spontaneous movement, but on partial asphyxiation the adductor spasm was followed by abduction of both cords which soon ceased in the right. At the end of seven months both cords were observed to be moving during tranquil respiration, but the excursions of the right cord were not so wide as those of the left.

It may be noted that the movement of adduction, induced by partial asphyxiation, reappears before that of abduction, which corresponds to the weaker extensor movement in the limbs. This is in keeping with the disappearance of abduction earlier than adduction in paralysis of the vocal cords, supervening slowly under pathological conditions.

It is shown from these experiments that spontaneous respiratory movements can be restored to the vocal cord by an anastomosis between the recurrent laryngeal and the phrenic. The entire trunk of the phrenic is not necessary, and probably it will be found sufficient to use half the trunk, as in a lateral anastomosis, or one of the roots arising from the cervical nerves.

No case has so far presented itself in which an operation for the relief of a paralysed cord appeared justifiable in the human being, but if such should be undertaken it is suggested that the appropriate operation would be an end-to-side anastomosis between the recurrent laryngeal and the phrenic.

## SPINAL ANAESTHESIA BY STOVAINE.

BY

ROBERT B. COLEMAN, M.B., CH.B. BIRM.,  
CHURCH MISSIONARY HOSPITAL, OLD CAIRO, EGYPT.

In the Church Missionary Society's Hospital in Old Cairo, Egypt, spinal anaesthesia is now used as routine in all suitable operations by all the five surgeons on the staff. A beginning was made about eight years ago, when this method was used in a certain number of picked cases. It took some time for it to become popular with more than one or two of the surgeons, and the Egyptian fellahs patients were inclined at first to resent this new method, expecting to be given something to inhale, as all their relations and friends had told them was regularly done. Little by little its scope was increased, till by the end of 1924 it was used in every suitable case unless there was some contraindication.

Exact numbers of cases are not available, but they amounted to more than 5,000 down to February, 1925, and at the present time we are doing about 2,400 a year.

#### Solution Used.

Stovaine is the drug used. Tropacocaine was tried, but did not give quite such good results in our hands. I do not know the reason for this, as Professor Morrison of Birmingham, one of the pioneers in spinal anaesthesia, found it so satisfactory.<sup>1</sup> For some time the ampoules of stovaine billion were used, but later were discarded, chiefly on the ground of expense, and lately we have ampoules put up for us by Messrs. Parke, Davis and Co., as follows: stovaine 0.1 gram, sodium chloride 0.1 gram, sterile distilled water to 1 c.cm. They are sent out to us a thousand at a time, and have proved consistently satisfactory. Their simplicity seems to add to their efficiency.

#### Type of Case.

The following comparative summary of the last 2,000 cases covers a period of about ten months, and shows how varied are the operations included.

Abdominal sections (including splenectomy, gastro-enterostomy, intestinal anastomosis, appendicectomy, hysterectomy, ovariectomy, etc.) ...	56
Vaginal and uterine operations (colporrhaphy, perineorrhaphy, curetting, etc.) ...	121
For inguinal hernia ...	330
For hydrocele, varicocele, etc. ...	210
Lithotripsy ...	51
Suprapubic cystotomy (large stone, prostate, etc.) ...	43
Nephrectomy ...	3
For urinary fistula ...	57
For haemorrhoids ...	518
For rectal bilharzial papillomata ...	461
For fistula in ano, ischio-rectal abscess ...	112
Amputations ...	8
For injuries and various conditions ...	30
	2,000

It is only lately that the larger operations in the upper abdomen have been attempted by this method of anaes-

thesia, and they have been attended with great success. In eight cases of splenectomy (very large spleens in Egyptian splenomegaly) it has proved a real boon.

Previous to the use of spinal anaesthesia chloroform was mostly used, as we very seldom use ether for general anaesthesia in this climate. But now we are using very little chloroform, except in small children. Everything up to the costal margin is done with spinal anaesthesia, and many head and neck operations are done under ether by the rectum.

#### Method of Administration.

The anaesthetic is given in the theatre on the operating table by the surgeon himself. The patient is made to sit up and bend forwards; tincture of iodine is applied over the spines and the right space selected. This varies with the operation. The second lumbar is the most usual, but we go as high as the eleventh dorsal when necessary. The needle is inserted in the middle line, and the experience gained makes it a very easy matter to know exactly the required depth it is necessary to penetrate. If the fluid does not flow briskly the needle is turned round or pushed further or slightly withdrawn to obtain this result, and the syringe is applied. We prefer to allow as little fluid as possible to escape. This has been our practice for about the last thousand cases, with better results. A 2 c.cm. syringe is used and the spinal fluid is allowed to mix with the 1 c.cm. of the fluid in this, and the whole is injected. The whole ampoule is given for an average operation in an adult, and proportional doses for children or weak patients, or very brief operations. On withdrawing the needle a small piece of adhesive plaster is applied to the site of the puncture, and the patient lies down flat. The field of operation is then prepared in the usual manner, and by the time this is done and the surgeon is ready the operation can be commenced. In an operation on the kidney a few minutes lying flat is allowed before the patient is put on his side. The high Trendelenburg position can be safely used by the time the surgeon is ready to begin. The analgesic effect lasts generally forty-five to sixty minutes, which is sufficient for nearly all operations. Operation for double inguinal hernia and double hydrocele in one subject is often done by a quick surgeon under the usual dose. Morphine and atropine are given previously as routine in all big cases—for example, abdominal sections, etc.

A few patients who are nervous and frightened imagine they feel pain without really doing so, but a few drops of chloroform on a mask make them happy and comfortable. They remain conscious but are contented. I have known a patient who was complaining of pain become quite happy for the whole time with not more than six drops of chloroform. A patient is sometimes surprised to find he can move his legs and yet feel no sensation. Occasionally during the course of an operation the patient feels slight malaise and has a little retching, but a spoonful of brandy, with a little water, by the mouth nearly always settles this rapidly.

There is a wonderful absence of danger with this type of anaesthesia. There has been no fatality which could really be attributed to the stovaine in the whole series of more than 5,000 cases. There was one case, early in the series, where the patient died on the table. The patient was an old man who had a strangulated hernia. He was kept for four days in his village and then brought up a long journey to the hospital, finishing up by travelling by tram and walking in, so that he was in a very poor state. As soon as the stovaine was injected he collapsed and died. We feel that it was the man's condition that killed him, and that it is not fair to attribute it to the anaesthetic.

#### Advantages.

The advantages are very marked from the point of view of both surgeon and patient.

1. *Saving of Time between Operations.*—This means a great deal in a busy surgical hospital. It would be impossible to get through some of our days with general anaesthesia. We often have twenty to thirty operations in a morning in two or three theatres. It is a great thing for the surgeon not to have that weary waiting between

operations till the patient is sufficiently under, which can scarcely be avoided with general anaesthesia unless there are two anaesthetists. He can literally go straight on from case to case. As soon as one is wheeled out the next comes in and can sit up and have the injection at once.

2. *Saving of Time during Operations.*—One needs to experience this to know it. The relaxation is always equal to, or better than, that which is only sometimes obtained by the very best general anaesthetics. This means much greater ease and rapidity for the surgeon. It is a great time-saver in operations deep in the pelvis, such as Wertheim's hysterectomy. Also in bladder cases, prostatectomy, lithotripsy, and so on, it is a great help to have complete absence of straining.

3. *Saving of Work after Operation.*—The work on the nursing staff in the surgical wards is wonderfully lessened on operating days. The patients come back from the theatre conscious and fit; they have no vomiting or restlessness, and seldom need a nurse to sit by them.

4. *Saving of Staff during and after Operation.*—Not only can the surgeon dispense with an anaesthetist, but in many cases he needs less assistance at the operation owing to the good relaxation. This in addition to the saving of nursing staff in the wards after, as mentioned above.

5. *Avoidance of Troublesome or Serious Symptoms.*—From the patient's point of view there is much in favour of spinal anaesthesia, including avoidance of vomiting and distressing malaise after operation, and absence of shock. In this latter respect undoubtedly many lives are saved every year in patients who would not stand a general anaesthetic, especially in cases such as late strangulated hernia, septic appendicitis, serious injuries necessitating amputation, etc. This is noticeable in such a country as Egypt, where the people are often so late in seeking advice. There is also less risk of chest complications following operation.

#### Disadvantages.

There is the real disadvantage that a great number of people think they would prefer to be asleep. This is largely a matter of its being the more usual thing. Our patients here now almost all wish for spinal anaesthesia because it is the usual method. We have had many cases, some among our own workers, who have had two operations at different times, one with general anaesthesia and one with spinal, and without exception they all vote for spinal. This is a real test. A certain small number complain of headache for some days after. Our later experience is that this symptom is noticed less and less. It has certainly been less frequent since we have only allowed as little spinal fluid as possible to escape. It is troublesome, but not serious, and at present it is almost negligible in our wards. Considering the small proportion of such cases it is a very slight disadvantage and compares favourably with the symptom of post-anaesthetic vomiting after general anaesthesia.

There is the fact that very occasionally the stovaine fails to act, but these cases are very rare, and chloroform can then always be administered.

Some people have a fear of paralysis or paresis following spinal anaesthesia. I have never seen such a case, and think there is no foundation for such fear. It would be interesting to hear of authentic cases.

It is worthy of a more extended trial by others than the few enthusiasts in favour of it; certainly for foreign hospitals, where the proportion of surgical work to number of staff is so far greater than at home, it is of inestimable value. It is very considerably used in other hospitals in Egypt, as is shown by the report of Mr. Morrison of Alexandria.<sup>2</sup>

I must acknowledge my gratitude to my colleagues Mr. F. O. Lashley, Mr. J. E. Bateman, Dr. Towfeek Negibe, and Dr. Andrew Shakhshiri, for allowing me to include their results in this report.

# RHEUMATIC INFECTION IN CHILDHOOD: THE SUBCUTANEOUS FIBROID NODULE AS AN EARLY MANIFESTATION.

BY

VINCENT COATES, M.C., M.A., M.D. CANTAB.,  
PHYSICIAN, ROYAL MINERAL WATER HOSPITAL, BATH, AND TO OUT-PATIENTS,  
ROYAL HOSPITAL FOR SICK CHILDREN AND WOMEN, BRISTOL;  
ASSISTANT PHYSICIAN, ROYAL UNITED HOSPITAL, BATH.

Rheumatic infection in childhood is likely to be overlooked until such time as one of the periodic exacerbations of the smouldering infection occurs, since at other times physical signs are in abeyance. It has been stated that subcutaneous rheumatic nodules usually make their appearance only in grave affections associated with gross cardiac disease. Arguing, however, on analogy with the findings in adults suffering from fibrositis, it did not seem improbable that nodules less obvious than those of graver infection might be discovered in subacute cases. When this suggestion had

toxic state could be elicited except *Ascaris lumbricoides* in two instances, efficient treatment of which did not alleviate symptoms complained of. The cases are divided into groups as follows:

1. Without nodules and without cardiac bruits, or cardiac enlargement or chorea (1 case).
2. Without nodules, but with cardiac bruits or cardiac enlargement or chorea (4 cases).
3. With nodules, without cardiac bruits or cardiac enlargement or chorea (6 cases).
4. With nodules, prior to cardiac bruits or cardiac enlargement (5 cases).
5. With nodules concomitant with or subsequent to cardiac bruits, cardiac enlargement or chorea (7 cases).

No nodules could be found in any of the remaining 77 children. Sir Thomas Barlow,<sup>1</sup> in his classical paper, considered subcutaneous nodules "in themselves indicative of rheumatism, even in the absence of pain," and "although unimportant in themselves are nevertheless of serious import." Bronson and Carr<sup>2</sup> quote instances to illustrate the general fact that "the nodules are a sign of some active rheumatic focus and that they tend to disappear as the infection becomes quiescent." It is contended that nodules

FIG. 1.—Arteriole showing proliferation of lining endothelial cells. Perivascular mononuclear proliferation. Obj. 1/12 oil immersion (Zeiss). Eyepiece Leitz I.

FIG. 2.—Cellular collections, mainly histiocytic in type. Obj. 1/12 oil immersion (Zeiss). Eyepiece Leitz I.

been established in part by the examination of children known to be suffering from rheumatic infection, one hundred consecutive children between the ages of 2 and 12 years attending the out-patient department at the Royal United Hospital were examined very carefully for subcutaneous nodules irrespective of the complaints for which they were brought to the hospital.

In searching for the nodules particular attention was paid to the spinous processes of the vertebrae and to the olecranon processes. Both superficial and deep palpation was adopted; a slightly flexed position of the spine and flexion to a right angle of the elbow-joint were found to be most satisfactory, with a moderately firm application of the examining forefinger, using a to-and-fro movement on the olecranon and a rotatory movement on the spinal column. The nodules appeared to vary in size from a small sago grain to that of a pin's head, and were often in small clusters. Synovitic creaking was often obvious round the vertebral spines and is most characteristic. Individual observers vary in ability to palpate nodules, and a good deal of practice is necessary.

It has been found that the easiest way to remove nodules which are smaller in size than the impression conveyed by palpation through the subcutaneous tissues is to cut down on to a hypodermic needle thrust under the nodule. Of the 100 children, 23 gave a history suggesting rheumatic infection, and in these no other causes of a

are a definite objective physical sign which can be elicited in a large number of children who present themselves as out-patients suffering from subjective symptoms suggesting rheumatic infection, prior to clinically demonstrable cardiac lesions.

I have to thank Professor Walker Hall of the University of Bristol for making sections of nodules removed from two children and for the following reports.

Fig. 1: The nodule is composed of fibrillar tissue, aggregations of histiocytes, and inflamed blood vessels. Some of the smaller arterioles show punctate proliferations of the lining endothelial cells. Perivascular proliferations of the lining endothelial cells. Perivascular mononuclear proliferation is frequent. The connective tissue contains many nodular collections of histiocytes. As yet these do not present any signs of necrosis. It is obvious that the etiology of the nodule may be associated with a persistent irritant of the subinfective or mildly infective type.

Fig. 2: The nodule is made up of fibrous tissue, a persistent medium consistence, and in places shows hyaline changes. The blood vessels present intimal and subintimal cellular proliferation and necrosis, and are in an early stage of endarteritis. The cellular collections are mainly histiocytic in type, without any necrotic change.

Further work is being done, and it is hoped to supplement this preliminary report with details in a larger number of rheumatic children at an early date, in conjunction with Dr. R. E. Thomas of the school medical service, Bath.

## INDUCED LEUCOCYTOSIS IN THE TREATMENT OF INFECTIONS.

BY

W. A. ELLIOTT, M.B., B.S. DURN.

SOME twelve months ago Dr. Burr Ferguson of the United States Public Health Service, Southampton, spoke to me of the results he had obtained by injections of mercury salicylate in the treatment of infective conditions, and I decided to try it in some suitable cases. The method consists in the intramuscular injection of a mixture of mercury salicylate in liquid paraffin (1 grain per cubic centimetre), 1 c.cm. being injected at intervals of one week up to four or six doses, or less if the desired result is obtained earlier. This is the usual method, of course, in treating syphilis. Some of the cases which I tried were as follows:

### CASE I.

A man, aged 46, with a condition of chronic infection of the lungs following pneumonia bronchiectasis, had attacks of pyrexia and chest pains whenever he had a chill; they confined him to bed and made him very ill for a time. There were physical signs of chronic pleurisy. He had been immersed in the sea for many hours after a torpedo attack on his ship during the war, and his chest trouble began subsequent to this. During one bad attack I waited until the more acute symptoms had subsided, and then gave him two injections of mercury salicylate, at an interval of five days. The result was a complete recovery, with abatement of all chest pains, and free and easy breathing. The patient was enthusiastic about the treatment. Previous to the injections he stated that he had a chronic depression of spirits, with a feeling as though there was a load on his chest and weights on his legs. After the injections he was buoyant again, and walked more lightly and with the elasticity which he used to have before his attack of pneumonia. The good results obtained have so far persisted.

### CASE II.

A man, aged 51, suffering from a fairly large carbuncle on the back of the neck, was confined to bed and suffered from much pain. The carbuncle was being treated with boric fomentations and was steadily enlarging and forming a central crater containing a large mass of hard dead epithelial debris. I gave an intramuscular injection of 1 c.cm. of mercury salicylate, and on the following morning there was a most perceptible softening of the mass. It continued daily to get rapidly better; the slough was cast off and an uneventful recovery ensued.

### CASE III.

A woman, aged between 50 and 60, was suffering from chronic dermatitis of the whole body, with bleb formation and much irritation. I treated this with calamine lotion, and in several weeks there was a marked improvement over the whole body, but new formations of blebs continued to appear. I therefore gave two injections of mercury salicylate at an interval of five days, and complete recovery ensued, no further outbreak of blebs occurring. The condition had been troubling her for many months.

For local infections of the skin I have long had a strong faith in calamine lotion, which seems to have a peculiar, or what is usually termed a "specific," effect in healing skin infection. Ferguson has investigated the results on the blood of the injection of mercury salicylate, with the assistance of Dr. Simson, who was tuberculosis officer at Southampton at the time. His results revealed an immediate general leucocytosis in the blood within twenty-four hours of the injection. He has found that certain salts of arsenic produce a similar effect, and that in malaria quinine produces a similar leucocytosis, though not so pronounced. The conclusions drawn are that the "specific" action of mercury, arsenic, and quinine in certain diseases is all due to a general leucocytosis produced in the blood.

In my opinion the local use of calamine lotion produces a local area of leucocytosis which causes its "specific" action in skin infections, and the same effect is produced by unguentum hydrargyri ammoniaci. In these cases the salts of the heavy metals zinc and mercury produce the result locally. I have repeatedly noticed a bluish coloration of the skin around the areas treated with calamine lotion, suggesting a blood change at that area. This leucocytosis of the blood is considered by Dr. Ferguson to be the reason for the happy results of intramuscular injections of mercury salicylate in infective conditions, the increased number of leucocytes killing the infective agents.

## OPHTHALMOLOGY IN EGYPT.\*

BY

A. F. MACCALLAN, C.B.E., M.D., F.R.C.S.,  
ASSISTANT OPHTHALMIC SURGEON, WESTMINSTER HOSPITAL;  
ASSISTANT SURGEON, ROYAL EYE HOSPITAL; FORMERLY  
DIRECTOR OF THE EGYPTIAN GOVERNMENT  
OPHTHALMIC HOSPITALS.

THE problem of subtropical ophthalmology, with which I have become familiar in Egypt, may be considered under two heads—first, as affecting the European population, and second, as affecting the native Egyptian population.

### EUROPEAN POPULATION.

1. *Effect of Sun, Dust, and Wind.*—The healthy emmetropic eye becomes painfully affected by the sun's glare in the summer when motoring or riding along dusty roads or over the desert. The heat rays from the red end of the spectrum which cause this may be prevented by wearing protective goggles of Crookes B or B2 material; but if discomfort is complained of the refraction of the patient should be verified under a cycloplegic. There are other varieties of protective glasses, which theoretically are more absorbent of the heat rays than Crookes glasses, as shown by Sir Arnold Lawson at the Ophthalmological Section recently, such as peacock-blue, feuzal, and amber. I have found in a large number of instances that ordinary glass, in which is included if necessary a very small ametropic correction, is all that is required. The effect of sun, dust, and wind in causing pinguecula and pterygium must be remembered.

2. *Effect of Fatigue, Ill Health, and Worry.*—Fatigue, ill health, and worry bring out latent defects in the eyes in any country. A hot climate causes greater fatigue than a temperate, and this may lead to fatigue indigestion, with resulting physical depression. Worry, whether official or private, similarly may cause ill health. Under these conditions trifling errors of refraction, if present, or slight degrees of heterophoria exert effects quite out of proportion to their actual severity. It is therefore of the greatest importance that correction of these errors should be made as carefully as possible, generally under a cycloplegic such as homatropin, and that the correcting spectacles should be adjusted accurately by the optician. In a highly sensitive patient, whose nerves are constantly being jarred by physical or mental discomforts, the correction of a very small degree of astigmatism may make all the difference between happiness and misery. The symptoms which patients with an uncorrected error of refraction complain of are headache, neuralgia, frequent frowning with consequent fatigue of the subcutaneous muscles of the forehead, indigestion, inflammation of the edges of the lids, with perhaps supuration of the glands of the lid margins, and so on.

3. *Effect of Acute Conjunctivitis.*—The same organisms cause this among the Europeans as among the Egyptians, and will be considered when speaking of the latter. I have seen acute gonococcal conjunctivitis in English children of 2 or 3 years of age, which had no doubt been contracted from the chronic gonococcal conjunctivitis of servants, without any suspicion of venereal taint.

4. *Effect of Chronic Conjunctivitis.*—The chronic conjunctivitis most prevalent in Egypt is trachoma. It occasionally attacks English children who have been taken care of by Egyptian or Nubian servants.

5. *Treatment.*—I have mentioned the importance of the accurate correction of ametropia; the glasses should always be worn in the sun and dust at any rate. This, with a good sun-hat, is all that is required in most cases, but tinted glasses may be ordered if they give relief to the patient. In dusty seasons it is most advisable to wash from the eyelids the dust which collects there and which may contain septic material. This should be done three times a day. In many cases this simple precaution is sufficient to prevent constantly recurring attacks of conjunctivitis. It must not be forgotten that dental apical abscesses and pyorrhoea are a fruitful source of ophthalmic trouble.

\* Abstract of a communication read at the Section of Tropical Medicine of the Royal Society of Medicine, February 12th, 1925.

## NATIVE POPULATION.

It is impossible to deal even cursorily with all the eye affections peculiar to a subtropical climate. I have, however, selected the following conditions about which to make some remarks: acute ophthalmias, chronic ophthalmias, ankylostomiasis and changes in the appearance of the fundus oculi, bilharziasis and eye conditions, an epidemic of chancres of the eyelid, and fly-blown orbit or orbital myiasis.

**Acute Ophthalmias.**—The number of new patients attending the hospitals is very much greater in the summer than in the winter, increasing from a winter figure of about 400 a day to a summer maximum of 2,800 a day. The increase is largely made up of acute conjunctivitis cases, especially of gonococcal conjunctivitis. This condition is usually of non-venereal origin, the infection spreading from eye to eye, by means of the fingers, towels, etc. Flies also play a part in the transference of the infection (this was discussed, but cannot be dealt with in an abstract). Traveling to the hospitals is easier in the summer, but the increase in the number of patients is more closely related to the increase of temperature, curves representing these showing similar variations.

[The author also dealt in some detail with the subjects mentioned in the previous paragraph.]

## Memoranda:

## MEDICAL, SURGICAL, OBSTETRICAL.

## DIPHTHERIA AT THE AGE OF SEVENTY-TWO.

In view of the rarity of diphtheria at any age over 50, the case here described may be worth publishing.

A lady, aged 72, was admitted on December 17th, 1924, for a fracture of the neck of the left humerus. She was feeble, childish, and demented. On January 24th, 1925, she was noticed to have a purulent, slightly haemorrhagic discharge from the left nostril. A case of diphtheria had occurred in the ward a few days before. A swab was forwarded to the Clinical Research Association, which reported Klebs-Loeffler bacilli present. There was no faucial exudation. A second swab on January 26th was also positive. In view of the unusual age, a third swab was taken on January 27th, from which the Clinical Research Association kindly did a test for virulence. A pure culture of Klebs-Loeffler bacilli was isolated and proved fatal to a guinea-pig in forty-eight hours. The patient's condition forbidding her transfer to an isolation hospital, she was isolated throughout in a small ward here. She received in all 24,000 units of antitoxin. A swab on February 12th was still positive. On February 20th, however, it was negative, and again on February 25th. Meanwhile, on February 23rd, she had a cerebral haemorrhage; she died on March 2nd. I do not think the diphtheria had anything to do with her death.

In my own experience, which has included three years in an isolation hospital, I never met with a case of diphtheria at this age, or indeed anywhere near it, nor have I heard of one.

I am indebted to my colleague, Dr. Thomas Dolan, for the prompt detection of the case, as well as for the treatment and notes.

London, E.11.

J. C. Muir.

GALL STONES IN A MALE AGED EIGHTEEN:  
CHOLECYSTECTOMY: RECOVERY.

I READ a report of this case to the Cambridge Medical Society on February 6th, and as no one present could parallel the age in a male subject I venture to think that it may be of sufficient interest for publication. I have heard of the same condition in a female of 16 years, at St. George's Hospital.

A somewhat frail-looking, pale undergraduate of 18, medium height, and spare, enjoyed ordinary health until the spring of 1924, when he had acute appendicitis, which was "sat on" for ten days. He was ultimately seen when an abscess had formed, and dealt with by a London surgeon, undergoing, in all, three operations. He made a good recovery.

For two or three weeks in November, 1924, the patient had discomfort in the epigastric region about one and a half hours after meals; this subsided with dieting and medicine. On November 17th, while walking in the street with a friend at 2.30 p.m., he was suddenly seized with violent abdominal (epigastric) pain, with difficulty, supported by his friend, who put him straight to bed, and called me to see him.

When I saw him at 3.15 p.m. he looked thoroughly ill. The temperature was 97.2° F., pulse 60, respirations costal. The pain

had become less severe. On palpation the upper right rectus muscle was rigid and exceedingly tender. There was no jaundice. The patient did not seem ill enough for perforation, yet the findings, in conjunction with the history and the age, seemed to suggest that the most probable provisional diagnosis was that of a perforated duodenal or gastric ulcer, and I therefore sent him to a nursing home for observation. At 4.30 he was easier, but the pulse had risen to 96. At 7 o'clock the pain had become very severe again, and he looked worse. Laparotomy was decided upon.

At 8.30 I made an upper right rectus incision, displacing the rectus outwards after freeing it in its sheath. When the peritoneal cavity was opened no evidence of any perforation was discovered, but the gall bladder was found to be acutely inflamed and markedly thickened, especially towards the proximal end; it contained small, easily palpable stones. The gall bladder was freed and excised, the ducts being found to be free from further stones. A tube was put in, down to the stump, and the abdomen closed in layers. The patient made a complete recovery.

**Pathological Report.**—"The stones were dark reddish-brown, and consist of bilirubin chiefly. The wall of the gall bladder is very markedly thickened and tough, and the mucosa is very dark red, and apparently haemorrhagic. Microscopic section shows congestion and haemorrhage into the mucosa, a little superficial ulceration of epithelium, and much submucous round-celled infiltration and fibrosis. A chronic cholecystitis with recent subacute inflammation."

Cambridge.

R. SALISBURY WOODS, M.D., F.R.C.S.

ANTERIOR POLIOMYELITIS, HERPES ZOSTER,  
AND VARICELLA IN SEQUENCE.

The following case seems of sufficient interest to place on record. The sequence of events—anterior poliomyelitis, herpes zoster, and finally varicella—suggest the possibility of some connexion between the three conditions.

G. E., a boy aged 5 years, was admitted to University College Hospital under the Surgical Unit on September 4th, 1924, suffering from anterior poliomyelitis affecting all the muscles of the left leg. The condition dated from ten weeks previously. It commenced with headache and malaise, rapidly followed by inability to move the left leg. On admission there was marked wasting of the muscles of the left leg; no voluntary movement was possible in it except to a slight extent through the action of the glutei. The boy was treated by extension on a Thomas's splint and massage.

By October 15th some power had been restored to the extensor muscles. Two days later his temperature rose to 99.4°, and on October 18th herpes zoster developed along the distribution of the first and second lumbar nerves on the right side; an increasing number of vesicles appeared during the succeeding days. By October 23rd the temperature had reached 101°, a generalized chicken-pox rash appeared, and the child was removed to the infirmary. Thirteen days later two further cases of varicella occurred in the ward in which the boy had been.

Another case illustrating the connexion between herpes zoster and chicken-pox occurred some years ago. A girl returned home from school suffering from herpes zoster; her brother, who had been playing with her, but had not been exposed to any other infectious case, developed typical varicella thirteen days after the return of his sister.

London, N.W.

H. S. MORLEY, M.R.C.S., L.R.C.P.

GUMMA OF CAECUM MISTAKEN FOR  
CHRONIC APPENDICITIS.

ABOUT a year ago I had occasion to treat a woman for a tertiary syphilitic condition. Her husband, when questioned, admitted that a few years previously he contracted syphilis, but that he was then quite "cured." I advised him to undergo treatment, but he refused. About a month afterwards I was called to see him. He complained of slight pain and discomfort in the right iliac region extending over a period of months; otherwise he stated that he was quite well and able to follow his daily occupation as driver of a wagon. I discovered a lump in the right iliac fossa, with slight tenderness on pressure, and made a provisional diagnosis of chronic appendicitis. I advised operation, and when I opened the abdomen discovered that the lump was an indurated, glistening enlargement of the lower end of the caecum, about the size of a duck's egg. The tumour had a springy feel, and the whole structure, including the appendix, was firmly bound to the posterior abdominal wall by a mass of adhesions. As it was futile to try to remove it the abdomen was closed.

When the abdominal incision healed sufficiently the patient was put on antisyphilitic treatment and the mass rapidly disappeared. When last heard from he stated that he was feeling quite fit and that the pain and discomfort previously complained of in the appendix region never troubled him again.

Lockport, Nova Scotia.

F. H. ALEXANDER, M.B., Ch.B.

BRAIN ABSCESS SIMULATING DEMENTIA  
PARALYTICA.

The following case may be of interest, as it shows how an abscess of the brain may cause many of the symptoms of general paralysis of the insane.

A man was admitted to this hospital on January 20th. He was dull and apathetic, listless, and indifferent to his surroundings; and had some difficulty in walking. No external marks were noticed on admission. His pupils were stationary, reflexes very exaggerated, gait unsteady, memory for recent and remote events poor, speech, though not slurring, very hesitant. He appeared to be drowsy. There was incontinence of urine and faeces. He was put on a liquid diet, which he was able to take without difficulty. In a few days he became less confused, and it was noticed that the left side of the body was paralysed. Lumbar puncture was performed on January 27th. The cerebro-spinal fluid was under very high pressure; the Ross-Jones and Weichbrodt tests were positive, as was the acetic anhydride, sulphuric acid test. The Wassermann test was positive 100 per cent. + 4 in the cerebro-spinal fluid and 40 per cent. + 2 in the serum. He was ordered potassium iodide 20 grains three times a day. On February 7th his temperature rose to 100° F.; the pulse was 140, respirations 22. At 9.30 the following morning he suddenly collapsed and died.

The necropsy revealed areas of suppuration in the upper and middle lobes of the right lung, and an area of softening in each corpus striatum and each internal capsule, more marked on the right side; otherwise the viscera were quite normal, and no gumata were found anywhere. The bacteriological examination of the abscesses showed some staphylococci and streptococci in the brain and the same in the lung with many other organisms.

The history, as given by deceased's wife, is that on January 13th the patient was knocked on the head by a trunk of a tree while unloading timber; that on January 15th he gradually became drowsy, complained of loss of memory, and could not look after himself.

S. GROSSMAN,  
Assistant Medical Officer,  
Cardiff City Mental Hospital.

INTRAPERICARDIAL RUPTURE OF AORTIC  
ANEURYSM IN AN INFANT.

The following notes on a case of aortic aneurysm in a child may be of interest, in view of the rarity of the condition at that age.

A male child, aged 20 months, was admitted on November 16th, 1924, with enlarged glands in the left anterior triangle of the neck and high temperature. The child was fairly well nourished but was very flabby, with yellow skin, and presented a somewhat cretinous general appearance. The enlargement of the glands was probably largely due to pediculosis capitis, as they subsided considerably after a week in hospital. The temperature ranged from 100° F. in the morning to 103° to 104° F. in the evening till death. The abdomen was rather large for the age and somewhat doughy, and a provisional diagnosis of tuberculous peritonitis was made. Nothing abnormal was discovered during the routine examination of heart and lungs.

On November 28th, while sitting up having its meal, the child suddenly turned pale and fell back, and when I saw it about two minutes later was dead.

I performed the *post-mortem* examination on the following day. On opening the pericardium a large fresh blood clot was seen enveloping the heart. The pericardium was quite smooth, except the visceral layer over the aneurysm, which had small fibrinous deposits. There was no blood in the mediastinum. The left ventricle showed moderate hypertrophy. The valves were normal. The foramen ovale and ductus arteriosus were closed. Commencing three-quarters of an inch above the aortic ring, the anterior and right walls of the aorta were deficient for seven-eighths of an inch, the aorta opening into a sacular aneurysm which extended along the upper end of the ascending aorta, covering its anterior and right aspects. The aneurysm was one inch in diameter. Practically the whole aneurysm was inside the pericardial sac. The inner wall of the aneurysm was shaggy; there was no recent clot. No definite opening could be found, but over an area a quarter of an inch in diameter on the anterior surface the wall of the aneurysm thinned down to the thickness of note-paper, and through this the blood must apparently have leaked.

The lungs were normal; the thymus also was normal in size for the age. The mediastinal lymph glands were enlarged; there was no caseation. The liver weighed 1 lb. 3 oz. fresh; there was no macroscopic evidence of cirrhosis. The abdominal glands were rather large; there was no caseation. The spleen, kidneys, and intestines were normal; there was no evidence of peritonitis.

The Wassermann test was not made, nor have I been able to obtain the consent of either of the parents to a blood examination; but when the child was in hospital, about three months previously, an entry in the notes stated "Liver enlarged, (?) congenital specific."

I am indebted to Dr. Williams for permission to publish these notes.

B. GLUCK, M.B., Ch.B.,  
Senior Resident Medical Officer, Kent and  
Canterbury Hospital, Canterbury.

## Reports of Societies.

## COCAINE: GOUT: COLLOIDS.

At a meeting of the Section of Therapeutics and Pharmacology of the Royal Society of Medicine, held on March 10th, with the President, Professor A. J. CLARK, in the chair, Dr. J. TREVAN gave an account of the physiological properties of some derivatives of cocaine.

Dr. Trevan explained that Miss Boock and he had carried out certain experiments on eleven derivatives of cocaine prepared by Mr. W. H. Gray. These derivatives had been obtained by substituting aromatic alcohols for the methyl group of the cocaine molecule, and the substances used for experimental purposes also included two derivatives of pseudo-cocaine. The toxicity of these various compounds was estimated by the effect of intravenous injection of solutions into mice: by using a sufficient number of mice the average lethal dose was obtained for each derivative, and this was used for comparison with the figure obtained in the same way for cocaine. The series proved very irregular in its toxicity: the least toxic was the salic oil derivative. The next investigation was to estimate the anaesthetic power of the various compounds. Standard cocaine solution was instilled into one eye and a solution of the substance to be tested into the other, and it was sought to find the minimum concentration necessary to produce loss of the corneal reflex. The best results were given by the benzyl derivative of pseudo-cocaine. A further step in the investigation of the anaesthetic properties was a series of "blindfold tests" on guinea-pigs. One worker handed unknown solutions to the other, who injected them under shaved portions of the skin of the animals, which were then pricked over the site of the injections until they ceased to squeak. The time for this to take place was noted, and the results afterwards worked out with reference to the substance used and its concentration. An attempt had been made to determine a therapeutic ratio for each of the derivatives used. The average lethal dose was divided by the minimum anaesthetic concentration, and this again divided by the same figure for cocaine. Some of the derivatives showed a high therapeutic ratio. Dr. Trevan pointed out that the solubility of the various compounds added to the complexity of the problem, and, similarly, some of the derivatives were more irritant than others, which also had to be taken into account. Of the group examined, the pseudo-benzyl compound seemed to be the most satisfactory from all points of view.

Dr. J. H. BRAN inquired whether the constrictor action of the various compounds had been worked out, since it was important to know how far a low toxicity to animals was a guarantee of therapeutic usefulness. He asked whether any of the substances produced necrosis, for example. The President inquired if mice varied a great deal as to the lethal dose required. Dr. Trevan replied that there had not yet been time to investigate the constrictor action of the cocaine derivatives. With regard to the susceptibility of mice, ninety animals were necessary to get a result within 10 per cent. of accuracy.

Dr. W. J. SMITH JEROME read a paper on the unknown factors in gout. He apologized for submitting what was an unsubstantiated supposition, but he felt that his suggestions went a long way towards solving the problems long associated with the biochemical mechanism of gout. He suggested that there were two unknown factors in gout. The first was that in gout uric acid occurred in the body in an abnormal form. As a result of some infection certain tissue cells were broken down and their nuclein yielded an abnormal type of uric acid of a colloidal nature which was unable to pass through the kidneys and was retained. The ordinary crystalline variety of uric acid was excreted in the usual way. The second unknown factor was a disturbance of the saline equilibrium caused by a violation of Ringer's law. Dr. Jerome then described how his suggestions would explain the various problems of gout.

Miss STEADMAN reported her observations on the action of colloidal substances on blood elements and antibody content. She explained that she had attempted to find some experimental evidence of the mechanism by which colloidal

substances appeared to have a beneficial effect in certain infectious processes. Her experiments had consisted of investigations in animals as to the minimum effective dosage, the changes produced in the blood elements, the action of colloidal substances on a stationary condition of immunity, and as to whether the production of immunity could be stimulated by the injection of colloids. The colloidal preparations used consisted of iron, silver, gelatin, dextrine, peptone, agar, and an emulsion of typhoid bacilli, while a solution of crystalline iron sulphate was used as a control. As far as dosage was concerned, there appeared to be some relation between the amount of colloid used and the changes produced in the blood elements and in the general condition. With regard to immunity production the colloids alone appeared to have no effect, but a combined injection of colloidal substances and an emulsion of killed typhoid bacilli gave rise to a definite increase in agglutinating titre as compared with controls. Miss Steinhilber suggested that the effects produced were probably mainly due to an alteration in the permeability of the lining of the blood vessels.

Dr. DOROTHY HARE referred to the immense quantities of colloidal preparations used within recent years, and expressed the hope that Miss Steinhilber would be able to extend her work to the chronic infections in human beings.

The PRESIDENT welcomed a paper on this subject which gave some positive facts as to the result of the injection of colloidal substances, for which, he said, there was nothing on earth which had not been claimed. He inquired whether it was the metal or the protective colloid which was thought to produce the effects reported.

Miss STEINHILBER replied that she had made her own colloidal preparations of the metals so as to avoid this difficulty, and the effects produced were probably due to the metallic elements.

### CONTAGIOUS ABORTION AND UNDULANT FEVER.

A JOINT meeting of the Comparative Medicine, Tropical Diseases, and Obstetrics Sections of the Royal Society of Medicine was held on March 12th, with Professor L. S. DUNGEON, the President of the Tropical Diseases Section, in the chair.

A discussion on infective abortion in cattle and its relation to Mediterranean (undulant) fever was opened by Professor JOHN ERNE. He gave a brief summary of what was already known about the diseases. He stated that, while infection was frequently caused by ingestion of the bacillus, inoculation was also an undoubted mode of entry, by cuts and abrasions coming into contact with infective bedding and excreta. Other possible paths of entry were sexual and from the hands of the attendants conveying infected milk to a healthy udder. He stated that abortion was a very frequent symptom in cattle, but that only about half of the infected goats aborted. It was uncommon in women, although lactation was often reduced. The morphology of the organism varied. In Mediterranean fever it was typically coccoid with a tendency to lengthen somewhat in culture. In contagious abortion it was a definite bacillus. It was doubtful whether they were really identical morphologically. The great question was as to the pathogenicity of the bovine organism to man. Until 1920, when Bevan reported cases from Rhodesia, it had not even been suggested. Since then several instances had been reported. Evans in America had done considerable work with the serums, and was able to show that there were very close resemblances between the two. For example, an *abortus* bovine serum would agglutinate *melitensis* organisms, and vice versa. Diagnosis of the human *abortus* cases had been based so far almost entirely on clinical symptoms, and so far he was of the opinion that bovine abortion in man should be regarded as non-proven.

Mr. L. E. W. BEVAN, who was unable to attend, contributed a paper on the disease as it exists in Southern Rhodesia. He pointed out that one of the characteristic symptoms of *melitensis* infections in goats was abortion; but that veterinary surgeons generally did not consider the disease identical with that caused by *B. abortus* in cattle.

In the human disease in Rhodesia the organism was identical with *B. abortus*. Although infectious abortion had existed for a long time in cattle, it was only recently that the disease had been recorded in man. In that subject the fever was less undulant and more irregular and persistent than the Mediterranean type of undulant fever. In discussing the methods of control of the disease in Rhodesia, Mr. Bevan indicated that the prevention of infection to man was ultimately part of the duties of the veterinary department. In the prevention of the disease in cattle, he had for some years now been using a "devitalized" vaccine (which should not be confused with a "dead" vaccine). It was prepared by treating saline suspensions of living bacilli with chloroform. This agent ruptured the organism without destroying its toxins. He considered that this vaccine possessed more specific antigenic powers than those in which these properties had been partly or totally lost by heat, subcultivation, and so on. The vaccine was not curative, and merely set up a temporary immunity until the source of the infection could be removed.

Sir P. BASSETT-SMITH stated that, although undulant fever had been traced to India and South Africa, it was significant that no cases occurred in Great Britain, where a large percentage of the cattle were infected with *B. abortus*, which must be frequently ingested by man in the milk. He had recently examined 130 serums from patients (who were not suffering from undulant fever) for specific agglutinins, and found that only two were positive—and that only up to 1 in 40. This made it highly probable that there did not exist any immunity to the disease in Britain. Bacteriologically the Mediterranean fever organism when freshly isolated was always a coccus, which in culture became a bacillus. The colour varied, and he had found that colour reactions were useless. The clinical symptoms of the South African disease were not the same as those of undulant fever. It was premature to suggest that the organisms were identical; their pathogenicity was the only reliable test.

Professor LOUISE McILROY stated that she had been unable to isolate any causal organism from human abortions in this country. In the cases examined the organisms were obviously contaminations. Nor had she been able to implicate any bacterial origin in the epidemic abortion which she observed in 1919, and which was probably a toxæmia. She observed that a number of cases of recurring abortion were habitual. A woman in her first pregnancy would abort owing to some slight accident, and although apparently healthy would acquire the habit of aborting at subsequent pregnancies. There was no organism causing contagious abortion in woman other than syphilis.

Colonel J. C. KENNEDY stated that it was impossible to differentiate the two organisms, which had been placed by the Americans in a new genus, *Brucella*. Pathologically, also, they seemed to be identical except for men and monkeys. In the undulant fever work in Malta they had found what they took to be *M. melitensis* in cows, but which in the light of more modern work might well have been *B. abortus*. It was assumed that cow's milk would not carry the disease, and a special herd of cows had been reserved for the Governor's use. So far as he remembered there had been no cases of undulant fever in the Governor's household. Abortion did occasionally take place in the goat from *melitensis* infection.

Dr. J. T. DUNCAN gave a detailed account of a recent case of human undulant fever from Rhodesia examined by him. The patient, a butcher, had been resident in Southern Rhodesia for fifteen years. He did not drink goat's milk, but had been in the habit of taking large quantities of cow's milk. When seen by Dr. Duncan the disease was at least six months old. A blood culture was made of the organism, which belonged to the *Brucella* group, and was present in a state of purity. It was indistinguishable morphologically from *B. melitensis* when cultivated under similar conditions. Using the patient's serum, a stock *melitensis* serum, and an *abortus* serum of bovine origin, he had carried out cross-absorption tests. The differences, as a rule, were slight; but in cases where there were differences the Rhodesian strain always

resembled the *abortus* strain more closely than it did the *melitensis*. Cultures were also made, and in these also the Rhodesian organism was very similar to *B. abortus*. Cultures of the three strains were also examined in lacrimal secretion in the hope that some special human affinities might be found, but there was never any evidence of lysis. Dr. Duncan believed that the weight of the evidence pointed to *B. abortus* as the cause of Rhodesian undulant fever in man, and the cow as the source of infection. Experimental proof was still awaited; as also was a really trustworthy test to distinguish *B. abortus* from *B. melitensis*. He was unable to state why *B. abortus* should be pathogenic for man in Rhodesia and not elsewhere.

Dr. H. H. SCOTT drew attention to an interesting and suggestive paper by Fica and Alessandrini which had been recently published, and which, if confirmed, might help to simplify the distinction between the two organisms. These authors record two cases of undulant fever due to *B. abortus*. The symptoms agreed with those in the *melitensis* disease, except that the fever was less undulant and more persistent. They had found that if the serum before being inactivated were diluted with distilled water (instead of saline) to 1 in 50, and subsequent dilution made with saline, then true antimelitensis serum would not agglutinate after heating for half an hour at 65° C.; but that antiabortus serum would agglutinate when heated to this temperature, and even up to 75° C. Dr. Scott suggested that if this method were found to be practicable on further investigation, then a very useful technique would be available for distinguishing the two varieties of the disease.

Mr. A. L. SHEATHER pointed out that once cattle had aborted from the disease they often did not abort at future pregnancies, although remaining carriers of the bacillus. A farmer who attempted to eliminate the disease by attending only to aborting animals was doomed to failure. In fact, cattle did not necessarily abort at all. There were no definite lesions associated with the disease in cows except when in calf; in fact, the disease could be said not to exist in non-pregnant cows. Abortion took place in the great majority of cases about the seventh month—not, as had been suggested, earlier in the first abortion, later in the next, and so on, ultimately disappearing. This was certainly not the case. He had also found that all antiserums were useless in the treatment of bovine abortion. In connexion with the non-specificity of serums, he recalled the case of a man who, suffering definitely from glanders (proved by means of diagnostic bacteriological tests), had a serum which reacted to *B. typhosus*, an organism from which he had never suffered.

### NEUROCYTOMA.

A MEETING of the Medico-Chirurgical Society of Edinburgh was held on March 4th, with Sir DAVID WALLACE, the President, in the chair.

Dr. R. A. FLEMING and Dr. JAMES DAVIDSON reported a case of neurocytoma in a boy aged 4 years.

The patient, admitted to hospital on December 15th, 1923, presented a remarkable appearance: he had a large head, the vertex overhanging a rather small face. There was considerable asymmetry, the left frontal and the left and right parietal regions showing marked local prominences suggestive of tumour formation. Extensive ecchymoses involved both eyelids; the superficial veins over the forehead, lateral and occipital regions were greatly dilated, and there was proptosis of both eyes. The boy was quite blind and corneal ulceration had begun in both eyes. The sutures of the skull gaped and both fontanelles were patent and pulsating. The spleen and lymph glands were somewhat enlarged. The blood showed the picture of pernicious anaemia. There was no optic atrophy, nor neuritis, but the boy suffered from attacks of vomiting preceded by nausea, and not of the usual cerebral type. His memory was good and intelligence average. The diagnosis during life was difficult, chloroma and suprarenal tumour being considered. The chief points in the history were as follows. About October 5th, 1923, the boy had fallen out of bed a distance of two feet and landed on his head. He got back to bed unassisted and made no complaint of pain. A day or two later he was found to be a little deaf, and a week later both eyelids were seen to be discoloured. Soon after this he began to have sudden severe intermittent attacks of pain in the head, referred to both temples and the top of the head; he also had occasional attacks of vomiting. His head progressively enlarged and the eyeballs became prominent. The boy's previous health and family history were satisfactory.

At the necropsy a large homogeneous mass was found replacing the left suprarenal gland. Metastatic growths were found in the liver, pancreas, lymph glands, and the long bones. The cranium was the site of large growths involving the subcutaneous tissues of the scalp and eroding and involving the bones so that most of the extracranial cavity was occupied by malignant growth. The growth had extended into the orbit, protruding externally and enucleating the eyeballs. The tumour had not become subdural at any part, and the brain was unaffected.

Dr. DAVIDSON showed lantern slides of sections through the tumour, demonstrating the nature of it to be neurocytoma. He commented on the recent changes in the interpretation of tumours of the nervous system, and pointed out that neoplasms of the nervous system might be composed of the developing cells of the various parts of that system. Thus tumours composed of cells which were the forebears of the sympathetic system, the chromaffin system, ganglion cells, or neuroglial cells, might occur. Tumours such as the case described were originally classified as sarcomata, and it was under this heading that Hutehison's ten cases reported in 1907 were placed. The course of these cases was similar to the case described, and the description of the histological appearances of the primary tumour corresponded very much with the appearances found in tumours which were now called neuroblastomata.

In the discussion which followed, Professor BRAMWELL described the case of a boy in which a brain tumour was found at autopsy, and in that case, as in Dr. Fleming's, the onset of the illness was referred to an injury. An actual causal relationship between trauma and brain tumour was, however, often questionable.

Dr. STEWART FOWLER said that in patients with the shape of the cranium as described in this case the diagnosis for all practical purposes rested between chloroma and suprarenal tumour. He referred to five cases in his own experience in which the diagnosis between these two conditions was frequently doubtful, as the blood picture in chloroma was not always characteristic.

### The Parkinsonian Syndrome.

Professor EDWIN BRAMWELL then read a paper entitled "The so-called Parkinsonian syndrome, with special reference to epidemic encephalitis." He drew attention to the frequency of appearance of this syndrome lately, and since it was typically met with in paralysis agitans he referred to this disorder. He pointed out that Parkinson, in his original definition, laid stress on tremor and lessened muscular power as the main symptoms. Later, Erb and Charcot drew attention to the rigidity, the immobility of the face, and the frequent absence of tremor. Discussing the pathology of this syndrome, Professor Bramwell referred to the various views held, and to the very general agreement nowadays that the lesion involved the basal ganglia. The fact that the syndrome was so frequently met with in epidemic encephalitis, and that the anatomical changes in that disease were situated more particularly, in the majority of cases, in the upper part of the brain stem, afforded corroborative evidence in support of the view that in paralysis agitans the causative lesion was situated in this region. The clinical features so far as the rigidity was concerned were summed up as a peculiar type of rigidity without spasticity, slowness of movement without actual voluntary motor weakness, a loss of automatic movement, and a tendency for the limbs to remain in a fixed position which had to be overcome by an effort of will. Professor Wilson's review of the dual innervation of muscle had stimulated observations and speculations relating to the subject of the mode of production of this peculiar type of muscular rigidity, but the brilliant experimental observations by the late Professor Irvine Hunter had served to replace pre-existing speculation by proved fact. Professor Bramwell referred to the plastic and contractile tone of muscle as demonstrated by Sherrington in the decerebrate animal, and said that Hunter's work on the wing of a bird after section of the somatic fibres justified the conclusion that the sympathetic nerve supply of skeletal muscle was responsible for the property of plastic tone. So, just as spasticity resulted from a lesion of the cortico-spinal neurons, exaggeration of plastic tone was produced by a lesion involving neurons associated with the corpus striatum and gave rise to the symptom-complex named the Parkinsonian syndrome. Both

those conditions were therefore release phenomena. The further interesting question arose: Assuming that corroboration was obtained of Ramsay Hunt's observations to the effect that the lesion in paralysis agitans was to be found in localized disease involving certain groups of neurons arising in the globus pallidus, was it the case that in epidemic encephalitis these neurons were actually affected and particularly selected?

In the discussion which followed, Sir DAVID WALLACE paid tribute to the brilliant work of John Irvine Hunter, and observed how much science had lost by his early and tragic death.

### ZOOLOGY IN THE MEDICAL CURRICULUM.

At a meeting of the Royal Medico-Chirurgical Society of Glasgow on March 6th, the President, Professor ARCHIBALD YOUNG, in the chair, Professor J. GRAHAM KERR communicated some general remarks upon zoology and the medical curriculum.

Professor Graham Kerr remarked that the attitude of the medical profession had changed greatly during the last few decades, it being now generally recognized that zoology was one of the important basic sciences in the medical training. It did not seem, however, to be within the domain of practical politics to advocate any extension of the time being given to this subject in the present congested state of the medical curriculum. A preliminary step would have to be the relief of that congestion, and at present there was no general agreement whether this could be best brought about by lengthening the curriculum, by reserving two preliminary years for a training in the basic sciences as in various American schools, by cutting down considerably the amount of post-registration chemistry, by relegating specialist courses to the post-graduation period, or by some other method. In the meantime the main determining factor in planning the course in zoology was the rigid time limit. Perhaps the most important object of the course was the training in biological method, which was the method used later on in the general work of the practitioner. It was not the method of the "exact" sciences consisting mainly of measurement and calculation, but rather the method used in early childhood, when by far the greater part of the mental development took place. In ordinary school training this method was replaced by the gulping down without question of information supplied by the teacher. The result was often disastrous as regards the development of the powers of observation and of reasoning from observations; to undo this harm and to develop further these powers was the chief function of the introductory zoological part of the curriculum. Emphasis was laid upon the special importance of drawing as a means of developing the powers of observation.

The part played by the course in zoology in leading up to anatomy, physiology, and pathology was emphasized, and Professor Kerr concluded by accentuating the importance of turning out the fully qualified practitioner at the end of his curriculum as a naturalist who would view the problems before him with the eye of the naturalist. Many of the greatest triumphs of medicine in the past—the solution of such problems as inflammation, malaria, yellow fever—had been reached by tackling particular problems as problems in natural history, and this would also be the case in the future. An avenue of great promise was the study of the internal medium of the body, in which the members of the cell community still led their ancestral aquatic existence. Slight deviations from the normal ordered complexity of this internal medium induced specific physiological reactions; greater deviations induced reactions which were recognized as pathological. The various normal activities of the living body were intimately adapted to the normal composition of the internal medium; included in these were the processes of normal cell multiplication and growth. It seemed to him probable that the deviation from the normal regular processes of growth, such as occurred in malignant growths, was in many cases due to an abnormal condition of the internal medium in some part of the body, the result of neighbouring associated tissues failing to supply their normal contribution. He suggested the great biological interest of experimentally injecting an extract of

pure connective tissue into actively growing epitheliomata. If the normal epithelial growth was dependent upon the connective tissue framework supplying its proper contribution, then irregularities in such growth might be expected to be countered by supplying the appropriate contribution artificially in the form of extract from a culture of pure connective tissue.

### HYPERTROPHY OF THE COLON.

A CLINICAL meeting of the Aberdeen Medico-Chirurgical Society was held on March 5th, the President (Dr. Peter Howie) in the chair. Dr. WILLIAM BROWN showed a case of Hirschsprung's disease in a boy of 3 years, the youngest of a family of eight. There was no history of tubercle or syphilis in the family, and the patient's Wassermann reaction was negative. Attacks of diarrhoea had occurred during the past eighteen months, with swelling of the abdomen, visible peristalsis, and rumbling noises which all disappeared temporarily when an aperient was given. There was no constipation. On admission to hospital peristalsis of the large bowel was visible. Screen examination after a barium enema showed an enormous pelvic colon lying in the right iliac fossa and extending up to the liver, with dilatation of the descending and transverse colon. Treatment consisted of lavage with saline solution, at first once, later twice, daily, with a weekly dose of castor oil. Great improvement followed, the peristalsis ceased, the abdomen decreased in size, and the tone of the wall improved. Recent examination showed that the calibre of the colon was smaller and the tone of its walls better. The patient was not confined to bed. Photographs and tracings of the radiographic examinations were exhibited.

Mr. ALEXANDER MITCHELL showed a case in which treatment of a streptococcal arthritis of the knee by Willem's method had resulted in a completely mobile joint. He emphasized the necessity for making the incisions the whole length of the joint, and for full active movement. Pain was an obstacle to movement, but by adopting Everidge's method of a back splint slung by an arrangement of weights and pulleys the effect of gravity could be almost entirely eliminated. Dr. A. G. ANDERSON showed a boy who had sustained a fracture of the skull in a motor accident; the signs and symptoms indicated the existence of a right-sided cortical lesion. Immediate operation revealed a diffuse meningeal haemorrhage, and decompression was followed by recovery, practically complete in two days. There were no sequelae. Dr. Anderson also exhibited a case of chronic adhesive mediastinitis in an adult woman, where the signs were cyanosis of the upper part of the body, breathlessness, and staring eyeballs. There was no evidence of aneurysm or neoplasm, and the condition was either tuberculous or syphilitic. Mr. WILLIAM ANDERSON showed a tailor, aged 31, who complained of loss of power in extending the fingers of the right hand. It was found that the extensores communis digitorum and carpi ulnaris did not react to faradism. There were no sensory changes. X-ray examination showed uniform thickening of the shaft of the radius, and the Wassermann reaction was strongly positive. All ordinary treatment by electricity and physiotherapy had proved useless. Mr. G. H. COLE demonstrated a small loose body removed from the upper end of the olecranon fossa in the elbow-joint. He raised the question whether the loose body was a chip off the epiphysis which had continued growing, nourished by the synovial fluid, or represented a complete ossific centre.

### THE PAINFUL DYSPEPSIAS.

At a meeting of the Brighton and Sussex Medico-Chirurgical Society on March 5th, Dr. E. F. MAYNARD, the President, in the chair, Mr. H. N. FLETCHER read a paper on some points in connexion with the painful dyspepsias and their diagnosis.

Mr. Fletcher remarked that the old view of hyperacidity as the cause of pain had been discarded, except in so far as it might be so indirectly; he then described the experiments of Hardt, Carlson, and others, and their evidence that increased intragastric tension was the true cause. Reference was made to the recent views of A. F. Hurst

as to how this increased tension was brought about by the reflex influence of diseased states within and without the stomach, and the need for further knowledge of the neuromuscular apparatus of the stomach, the exact part played by the vagus and sympathetic nerves, and their possible control through Keith's nodes was emphasized. Mr. Fletcher then described in detail the salient characteristics of the common causes of painful dyspepsias, gastric and duodenal ulcer, gastric cancer, cholecystitis, chronic appendicitis, visceroptosis, and "nervous" dyspepsias. He laid stress upon the paramount necessity of obtaining a detailed history and making a physical examination of the patient; he defined the important differential points concerned in diagnosis.

The PRESIDENT agreed with Mr. Fletcher regarding the time incidence of pain as a valuable means of differentiation between gastric and duodenal ulcer. Vomiting was not at all characteristic of gastric ulcer. With epigastric pains and vomiting present, not gastric ulcer but disease of the gall bladder or duct was suggested. The pain in the gall bladder radiated up to the right shoulder. Epigastric pain might be due to angina, pericarditis, or pleurisy. He considered that in neurasthenia there were almost as many cases of hypochlorhydria as hyperchlorhydria.

Mr. G. W. BERESFORD remarked that in neurasthenic subjects slight pain was exaggerated into severe pain. Excluding dyspepsia of nervous origin, epigastric pain was due to an organic lesion in the upper abdomen. He was doubtful about the existence of chronic appendix dyspepsia.

Dr. W. BROADBENT said that in his experience of duodenal ulcer there had seldom been any previous history of dyspepsia. He referred to the diminution in the number of gastric ulcers of recent years, and suggested that modern hygiene might account for this. Neurasthenic dyspeptics complained of very severe pain, but there was absence of tenderness on palpation.

Dr. DONALD HALL supported Mr. Fletcher's statement that  $\alpha$  rays were not so reliable in duodenal as in gastric ulcer, and quoted three cases.

A medical man, aged 47, had symptoms of duodenal ulcer for seven years, with typical time incidence, relieved by taking food and alkalis, and with the characteristic remissions. By  $\alpha$  rays a diagnosis was made of chronic duodenal ulcer, but a surgeon advised a course of strict Sippy dieting for six months. On this régime the patient was free from symptoms, but before the six months had elapsed he had for the first time pain and tenderness in the right iliac fossa. He was operated on the same evening, when the greater part of the appendix was found to be represented by a mere cord, while the proximal stump was acutely inflamed and would have progressed to perforation. That patient had had repeated mild attacks of obliterative inflammation without there being at any time pain or other symptoms in the region of the appendix; but in his case there was a possible fallacy, because the surgeon did not feel justified at the laparotomy in exploring the upper abdomen, and there might have been a coexisting duodenal ulcer. He had, however, on ordinary diet been free from symptoms now for eighteen months.

A middle-aged clergyman had suffered from painful dyspepsia for several years and had declined exploratory laparotomy. He had then been  $\alpha$ -rayed and was found to have dropped colon. After a sudden attack of acute agony, as from perforation, he was operated on, and a large tear was found in a chronic ulcer of the duodenum. He died on the following day.

A retired army officer, aged 56, with a long history of dyspeptic troubles, was radiographed. Lane's kiuk and visceroptosis were found, and after an elaborate surgical operation he was sent down to Brighton to convalesce. He became suddenly ill during lunch, and at first sight appeared to be dead. Later on he was found to have fainted as the result of severe internal hæmorrhage. Melaena was present for some days, and after medical treatment for several weeks gastro-enterostomy was performed and the clinical diagnosis of duodenal ulcer was confirmed.

Dr. Hall stated that he was a firm believer in "appendix dyspepsia" as a clinical entity, but where local signs were wanting the mentality of the patient must be carefully studied before operation. Abdominal operations based solely upon subjective symptoms were to be deprecated.

Dr. W. BARRINGTON PROWSE said that too much must not be expected from  $\alpha$ -ray examinations, and the result must always be taken in conjunction with the clinical evidence; but there was no doubt that  $\alpha$ -ray examinations were a very valuable help in doubtful cases. In supposed gastric cancer,  $\alpha$  rays were extremely valuable as a help in determining the question of operation.

## THE CATARRHAL CHILD.

A MEETING of the Bristol Medico-Chirurgical Society was held at the University on March 11th, the President, Dr. J. O. SYMES, in the chair. Dr. James Swain, O.B., C.B.E., M.S., who had been for twenty-five years a member of the Editorial Committee of the society's *Journal*, and for longer a very active member, was elected an honorary member of the society.

Dr. R. C. CLARKE opened a discussion on the catarrhal child. The views he wished to put forward might be new, but they were based on extensive observations in children's clinics of several thousand children, and represented ideas that had forced themselves upon him. The subject was one that had not received the attention it deserved. Only of late years had the routine examination of children supposedly healthy been systematically undertaken. When advice was sought only for acute bronchitis or bronchopneumonia, the significance of preceding bronchial infections might escape notice. Among children between 3 and 6 weeks old, not less than half were already subjects of respiratory catarrh; in the last thousand cases the exact figures were 499 with catarrh, 501 without. "Catarrh" was diagnosed on the simultaneous presence of three signs: (a) snuffles, (b) Harrison's sulcus, (c) definite bronchial catarrh, determined by auscultation. In this connexion, he wished to warn members about "snuffles." A nasal catarrh, a napkin rash, and the marasmus which followed inability to suck, from nasal obstruction, must not lead to the (false) diagnosis of congenital syphilis. When a young infant "caught cold," the first thing that occurred was nasal obstruction. The whole respiratory mechanism was thrown out of gear, for infants refused to breathe except through the nose. Only when half stifled would they open the mouth and breathe through that, so that sleep was disturbed. The drawing in of the lower ribs produced Harrison's sulcus; the latter was a sign solely of nasal obstruction. Rickets might emphasize it, but did not cause it. Since sucking was deficient, feeding became very difficult; if the child did not suck properly the natural stimulus of the breast was lost, and the breast milk might go—a disaster, especially among the poor.

The earlier the catarrh affected the child, the longer it took to clear up and the greater the certainty that the chest would be affected. If the first "cold" could be postponed till after the sixth month, it was practically certain that the chest would escape. But in a series of 400 sufferers, every baby that had nasal catarrh under 4 weeks old had bronchitis. Further, Dr. Clarke believed that once a child became bronchitic it remained bronchitic; every cold "flew to the chest," and it was proper to describe some children of only 6 months old as "chronic bronchitics." As the children grew up, the attacks continued; but between the acute attacks there could always be found signs in the chest. The bronchitic baby produced the bronchitic child, and later the bronchitic man; witness the almost invariable presence of Harrison's sulcus in pensioners with bronchitis. Further, he believed that chronic nasal catarrh was the one and only cause of "tonsils and adenoids"; the latter phenomenon was merely a part of the picture of chronic respiratory catarrh. A badly developed nasal organ, leading to deflection of the septum, and a permanently damaged mucosa, leading to chronic sinus disease, were other sequelae of the same condition. The otitis media, so very common among school children, was probably only a recurrence of an unnoticed otitis in infancy. The development of this catarrhal condition depended on two factors: (1) the number and virulence of the organisms reaching the mucosa; (2) the local and general resistance. (1) The amount of infection depended on the presence of persons carrying these organisms and the lack of ventilation. (2) As to resistance, he did not think the mucosa of the young infant had any power of resistance; and the membrane which had been subjected to repeated infection never gained this power, which was otherwise definite. The very young baby invariably got the whole respiratory tract infected if any part was involved.

Dr. Clarke maintained that prophylaxis of this condition was not difficult. During the first six months of

life every effort must be made to avoid infection. The baby should live in the open air, even in a draught; this rule should not be broken even during the bath. The mother should be examined to exclude chronic suppurative rhinitis; if this was found, the use of a mask during the whole time that she was doing anything for the infant was important. The same rule applied to the nurse, though no nurse with a definite nasal infection should be engaged. All visitors should be subjected to the same rule, and never allowed to kiss the child. The parent, nurse, or other children who were carriers—those who nourished the organisms of disease without manifesting symptoms—presented a difficulty. As for treatment of older children, this was important, because the mucous membrane, if preserved from repeated infection, did recover some power of resistance. Hopelessly infected tonsils and adenoids should be removed. The same general hygienic rules as for infants should be observed; the child should live in the open air, and visits to the cinema, and parties, should be reduced to a minimum. Cod-liver oil was the only medicine of any value.

The PRESIDENT thought that Dr. Clarke had described an entirely new disease. According to the thesis, 50 per cent. of all children born got bronchitis within four weeks of birth and were bronchitic thereafter. For his part, he had not met with this disease. He thought that up to 6 months of age children were extraordinarily immune to infection. The picture they had had presented might be produced by underfeeding, rickets, or teething—all might manifest "catarrh" without there being any infection. Dr. Symes suggested that small children did not readily clear the trachea of secretion, which might lead to râles, etc.

Dr. C. E. K. HENRATH agreed with Dr. Clarke. He thought this a disease of the hospital class. As for clearing the air passages, very young babies sneezed more than adults. Mr. J. P. I. HARRY believed that infection of the air passages could take place at a later age than that discussed by Dr. Clarke, especially from parent or nurse. Otitis media was quite common at the very earliest ages. He thought adenoids should be removed at any age, without waiting.

Dr. P. WATSON-WILLIAMS thought Dr. Clarke wanted to make their flesh creep. He was glad to hear that Dr. Clarke thought "tonsils and adenoids" were a response to infection. "Catarrh" was the important matter. One should not remove the tonsils in very young children; these glands had often great value in the fight with infection, and should be preserved as long as possible. Having had many years' experience as a physician, and given especial attention to the chest, he could not agree with the large incidence of bronchitis described. He was interested in Dr. Clarke's observations on sinus disease in families; he had had many cases where sinus disease in all the children of a family coexisted with a latent sinus infection—perhaps producing no symptoms—in one or other parent.

Dr. R. A. ASKINS (school medical officer) thought 20 per cent. of all children of school age suffered from adenoids. The prevention of so much sickness was of first importance. Further, bronchitis was very common among the children at primary schools. He had observed the frequency with which the operative treatment of tonsils and adenoids was needed in all members of a family. He considered that children had some inherited immunity in respect of ordinary infections, which lasted for some months after birth; but this did not occur with catarrhal infections.

Dr. J. A. NIXON thought that though Dr. Clarke's views were extremely heterodox, they drew attention to an important aspect of catarrh. Why should the chronic sequelae of catarrh occur only in the poorer classes? What factor was concerned other than perhaps feeding? He thought it very necessary to guard the newborn from loss of heat—mistake catarrh for congenital syphilis; in the latter the discharge was purulent. He agreed that Harrison's suture was a sign of nasal obstruction only. Dr. Clarke had omitted the question of asthmatic children, those sensitive to certain proteins; such a condition might lead to bronchitis.

Dr. J. R. R. TRIST called attention to the extreme sensitivity of other mucous membranes, such as the vaginal, in the young child. He agreed with the view that young children should be properly protected from loss of heat. Dr. C. J. C. FAYLL remarked that the tuberculous child was not "catarrhal." If children were to be exposed in all weathers to the open air—that is, naked—they must have bronzed skin and be well fed; then they did not require clothing. Mr. A. W. ADAMS pointed out that newborn babies seemed immune from empyema; he thought this could hardly be consistent with such a very high incidence of bronchial infection. Dr. J. A. BRINELL felt that perhaps Dr. Clarke had mistaken the sounds produced by a flapping soft palate for bronchial râles. Did asthma occur at the age of a few weeks, and was "croup" a condition analogous to asthma? He could not agree that newborn children might safely be exposed to cold.

Dr. CLARKE, in reply, said that he thought the newborn child was infected very readily. Pneumonia did occur in children of this age, and explained some of the cases of "sudden death" in infants. His figures were from four clinics, but all from the lower strata of the population. Catarrh did not confer any immunity, but rather predisposed to a further infection. He had formerly thought that repeated infection was the principal factor in producing the chronic catarrhal child, but he now thought that the earliness of the infection was the real deciding factor. Children did not seem to mind the cold; but the poor used much more clothing for their children than the well-to-do. He thought most cases of asthma in young children were really bronchitic.

Mr. H. CHURCH showed three cases: (1) Osteomalacia in a girl of 18; union of ununited fractures of the tibiae followed local injections of colloidal magnesium. (2) Ununited fracture of the tibia in a child of 5; local injections of magnesium, and a rib graft, had alike proved ineffectual. (3) Double pleural empyema in a child; both sides of the chest were opened at the same operation, with perfect result.

Mr. A. W. ADAMS showed a case of malignant disease of the thyroid, with secondary glands, relieved by operation; specimens and sections were shown with the case.

## HERNIA THROUGH THE TRANSVERSE MESOCOLON.

At a pathological meeting, on February 26th, at the Liverpool Medical Institution, Mr. HEANEY and Mr. SIMPSON read a note on two cases of hernia through the transverse mesocolon into the lesser sac. One case was in a woman, aged 52, with many years' history of gastric trouble. The whole of the small intestines, except the last few inches, had passed into the lesser sac and then returned through the gastro-hepatic omentum. A marked degree of hour-glass contraction of the stomach occurred where the coils crossed the stomach. The hernia was reduced and a gastro-enterostomy performed; the patient died eleven months later of valvular disease. The other case, in a woman aged 38, gave a sixteen years' history of gastric disturbance. The whole intestine had passed into the lesser sac, but had emerged again through the gastro-ocolic omentum; there was hour-glass contraction of the stomach and an ulcer on the lesser curvature. Reduction of the hernia with excision of the lower sac and ulcer proved successful and the patient recovered completely. The seventeen cases collected by Rendle Short were alluded to, and also a case recorded by Coffey; in no previous cases had definite hour-glass contraction been found. The second case was exceptionally interesting, since in Pringle's case, and also in the case illustrated by Crimble, adhesions had much obscured the picture.

Mr. Heaney and Mr. Simpson thought that the hernia was due to enteroptosis, and they discussed the origin of the hole in the transverse mesocolon, which might have been due to upward pressure on the small intestine behind the loaded colon, to congenital deficiency, to rupture of the sac, or to a retroperitoneal hernia into the rare inter-mesocolic fossa. Cases were mentioned of such congenital abnormalities occurring.

## Rebels.

### THE COCHLEA.

WILKINSON and GRAY, in their work on *The Mechanism of the Cochlea*,<sup>1</sup> recall the circumstance that Helmholtz undertook a minute study of the cochlea in the expectation of proving that it acted as a resonator, since he held that there existed no way by which the ear could analyse sounds except that of sympathetic vibration. He hoped to find in the cochlea some mechanism analogous to that of the piano, the strings of which vibrate sympathetically to sounds of similar vibrational rates emitted in their neighbourhood; the microscopical technique of his time was insufficiently advanced to furnish convincing proof of the truth of the theory. Other theories have since been mooted, resting on the supposition of analysis of sound impressions by the brain, but none have been proved and the mechanism of the cochlea is still a vexed question. The recent work of the authors, however, on the function of the spiral ligament, the principle of maximum stimulation, and the demonstration of the bearing of the factor of mass on the working of the cochlea, has removed most of the difficulties standing in the way of an acceptance of Helmholtz's theory, and the authors' book is a restatement of the resonance theory in the light of these new facts.

To appreciate the analogy between the cochlea and a stringed resonator such as the piano, it is necessary to imagine the cochlea unrolled. There will then appear a straight tube of bone, divided into an upper and a lower chamber by a delicate basilar membrane stretched across its cavity. The chambers, which are filled with fluid, have at the base of each a small window closed by membrane; the one membrane serves to transmit vibrations from the exterior to the fluid and basilar membrane, the other (that closing the foramen rotundum) allows, by a slight outward yielding, for the displacement of fluid caused by the vibration of the membrane. The problem is to show that the transverse sectors of the basilar membrane form a series analogous to the strings of a piano, as regards tension and other physical conditions. The essential features of the latter are that the strings are shorter and more tense in the higher octaves and become longer and less tense in passing down the scale; and that the thickness, or weight per unit of length, increases from above down in the series. In the mechanism of the cochlea, as expounded by the authors, these three factors—the serial variation in length, tension, and weight—appear to be represented. As regards length, the basilar membrane gradually increases in width from the base (that is, near the two foramina) to the apex; the transverse sectors therefore show a gradual increase in length. As regards tension, the authors have shown that the spiral ligament, by which one border of the membrane is attached to the bony wall, is stouter towards the narrow end of the membrane and gradually diminishes in thickness towards the broader end. From this it is inferred that the tension of the shorter sectors is greater than that of the longer. As regards weight, since there appears to be no appreciable difference in the thickness of the basilar membrane in its different parts, the necessary weighting has to be sought for outside the membrane, as in the case of the piano, where the lower strings are weighted with a close spiral of copper wire wound round them, without which vibration would be impossible. The authors consider that the necessary weighting is provided by the fluid in the lower chamber—that connected with the foramen rotundum, which, as before mentioned, is situated near the narrow end of the basilar membrane. Vibration of sectors in this situation will only entail movement in the small column of fluid between it and the foramen rotundum; while vibrations of sectors more remote from the foramen will involve movement in a column of fluid which increases in length with the increase in length of the vibrating sector. It is to the inertia of these varying columns of fluid that the authors ascribe the factor of weight.

<sup>1</sup> *The Mechanism of the Cochlea: A Restatement of the Resonance of Hearing.* By George Wilkinson, M.B. Cantab., F.R.C.S. Eng., and Albert A. Gray, M.D. Glasg., F.R.S.E. London: Macmillan and Co., Ltd. 1924. (Demy 8vo, pp. xx + 253; 50 figures. 12s. 6d. net.)

The book contains many other matters of interest connected with hearing, including an article on the damping of vibrations, by Professor Milner; and as it is written with exceptional clearness it will prove attractive to the intelligent layman as well as to the physiologist.

### BROCQ'S LECTURES ON DERMATOLOGY.

Brocq,<sup>2</sup> the doyen of French dermatology, has collected and published in a large volume many of his clinical lectures on certain types of skin disease. Although some of the lectures date from as far back as 1896, and some are as recent as 1923, there is an undoubted constancy of outlook throughout the whole series, which shows that, though the fundamental attitude of the distinguished author towards the problems of dermatology may have developed, it has certainly not essentially changed since the early stages of his career. The value of the book lies largely in the carefully detailed clinical observations and clinical histories derived by the author from his very extensive private practice over many years. These dermatological dramas he unfolds with all the felicity of phrase and epigrammatic skill which we have long learnt to associate with French medicine, and uses them to illustrate his favourite theses of cutaneous reaction and morbid predisposition with the most delightful aptitude. If a sceptical reader may be permitted to criticize ever so delicately, it might be hinted that the amazing accuracy with which the facts fit the author's theories is almost terrifying! While ready to avail himself of the new therapeutic weapons provided by modern research into the bacteriology of skin diseases, Brocq has taken little part in that work. He is essentially a clinical observer of great acumen and a therapeutic artist of much resource, rather than the apostle of scientific experiment.

Another great French dermatologist of a more modern generation, Sabouraud, has also recently published volumes of clinical lectures, and the two authors provide an interesting contrast. Both have busied themselves principally with the commoner dermatoses, but while Sabouraud has the distinction of having solved the problems of impetigo and ringworm by the purely scientific methods of the microscope and the test tube, the conditions which have occupied the mind of Brocq for the major part of his career—namely, the diverse manifestations of dermatitis or eczema, the production of lichenification, and the relations between dermatoses and the internal condition of the human organism—still present problems of etiology and pathology which are, for the most part, unanswered. Brocq can, however, claim to have put these problems in a form which at some future time will facilitate their scientific solution. It is also quite possible that the theories of cutaneous reaction and so on, with which he so skilfully fits his clinical experiences, may some day find a sure biochemical foundation as our knowledge of the delicate chemical mechanisms involved in human metabolism is further advanced. Brocq in this book does not confine himself entirely to theories: there are chapters on the treatment of acne, of eczema, of lupus erythematosus among other subjects, and, as would be expected, any medical man, whether specialist or general practitioner, can profit from the experience of so distinguished a dermatologist. Though the book is long, it will well repay trouble of perusal. Like many French publications, the printing is good; the forty-two photographs with which it is illustrated are well reproduced, but it is unbound, and it is sewn together so weakly and poorly that, in the words of the domestic servant, "It comes to pieces in the hand."

### GROWTH.

KNOWLEDGE concerning normal and abnormal growth has made great advances in recent times, so that the subject is now presentable in systematic form; it has an important bearing on pathological processes such as hypertrophy, inflammatory new-formation, and tumours. Apparently it is at present regarded as being too remote from the practical

<sup>2</sup> *Cliniques dermatologiques.* By L. Brocq. Paris: Masson et Cie. 1924. (Roy. 8vo, pp. 739; 54 figures. Fr. 60.)

matters of medicine, surgery, and gynaecology, to claim much of the student's time, but there is very little doubt that some day it will be recognized as one of the main foundations of pathology.

An excellent little book on *Growth*,<sup>3</sup> which every student may be recommended to read, has been written by Mr. DE BEER; it gives the main facts within a small compass, and clearly shows their bearing on pathological questions. Thus, one of the most interesting problems discussed is the limitation of the size of organs within definite bounds—the cessation of growth when the adult size and form have been reached. This is shown to be due, in part, to the balance between growth on the one hand and the metabolic wear and tear of the tissues on the other; but other factors come into play. Tissues of high metabolic activity are found to exercise an inhibitory influence on those of lower metabolic activity; for instance, the growing point of plants inhibits the growth of the nearest lateral buds within certain limits, and if the growing point is arrested in its development by artificial means the lateral buds will become dominant and grow, and the terminal bud will die. Another instance of the power of one tissue over another is seen in the culture of tissues *in vitro*. A piece of kidney will dedifferentiate and grow as a sheet of embryonic cells; apparently the separation from the control exerted by the rest of the organism sets free its inherent capacity for independent, undifferentiated growth. If, then, a piece of connective tissue be added to the culture, some of the cells will differentiate into tubules, characteristic of the kidney. Similarly, a culture of carcinoma of the breast produces an undifferentiated mass of cells, but the addition of connective tissue causes a differentiation in the direction of the normal breast tissue. Such observations as these would seem to throw considerable light on the nature of tumour formation.

The starting point and main theme around which de Beer's book is written is that growth is a fundamental property of living matter, and takes place whenever circumstances do not prevent it. The actual phenomena observed in growth are first described, and this is followed by the discussion of regeneration, asexual reproduction, abnormal growths, the causes and nature of growth, substances stimulating it, and external conditions affecting it. There are also interesting chapters on size, the rate of growth, and senility. A selected bibliography is appended to each chapter to guide the student in a more detailed study of the subject.

### THE NATURE OF THINGS.

SIR WILLIAM BRAGG is making a second reputation. The first was won by pioneering work in the borderland of physics and chemistry, and especially by the application of x rays for the determination of the architecture of crystals; the second is being gained by his exposition of such matters. His most recent book, for which he has borrowed the Lucretian title *Concerning the Nature of Things*,<sup>4</sup> is founded on a course of lectures given at the Royal Institution; it is concerned with the structure of atoms, with the nature of gases and liquids, and with crystals—the diamond, ice, and metals. The discussions on bubbles and scums in the chapter on liquids will perhaps be of special interest to medical folk, because, better than any other writing we have come across, it enables the reader to visualize the plan of a molecule and its relations to other molecules. Even the sketch here given is sufficient to make plain the amount of information of fundamental importance to physics Professor C. V. Boys has extracted from the soap bubble. It is a thin-walled air-filled sphere of solution bound within and without by a film of soap molecules with water molecules; it holds together by reason of the film, and the film holds together

owing to the properties of the soap molecule, of which Sir William Bragg writes:

"It is of very curious shape, many times as long as it is broad; and it is made up of a chain of carbon atoms fringed along its length with hydrogens, and ending, at one end, in a little bunch of three hydrogen atoms, at the other in a little group consisting of oxygen and sodium. The former of these bunches is very self-contained: its attractions for other atoms and molecules are small. But the latter is by no means so unsocial: it is an active group tending to enter into association with others, and especially it has a strong desire to join up with molecules of water, for which reason the soap dissolves in the water. Because, however, it is only one end of the chain which is very active in this respect—the other end and the sides of the chain behave differently—the soap molecules are apt to stay on the outer fringe of the water if they come there in the course of their wanderings. In this way a real film forms on the surface of the water, consisting of soap molecules standing on end, so to speak, one end rooted in the water, and the other exposed to the air. They are packed together side by side like the corn in a field, or the pile on a piece of velvet. They are not as free, however, as the hairs of the pile: they are tied together side by side, because there is some force of attraction between them when so laid alongside."

The behaviour of what we have for short called "scums" illustrates what happens when oils are allowed to spread on the surface of water. On to a perfectly clean water surface a powder, such as talc, is thinly dusted; a fine drawn glass point or needle is dipped in oil, and nearly all the oil wiped off; when this slightly greasy point is dipped into the dusted water surface a circle is instantly cleared around the needle; this is due to the activity of the oil molecules, which, spreading equally in all directions, drive away the dust particles.

"Each molecule hastens to root itself in the water by its active end, and stands upright, as if it were a water plant rooted and growing in the water. In the end all the molecules are successful, and a thin sheet, one molecule thick, covers the surface of the water; its thickness is of the order of a ten-millionth of an inch. By measuring the weight of the oil that has been placed on the water—a difficult task, since it is so small—and the area covered, it is possible to find a measure of the thickness of the film. . . . On the result of [this] work it was possible to assert that the thickness of the layer was such as would be expected if it were one molecule thick; and the argument was greatly strengthened by the fact that when different substances, known by chemists to be chain molecules of different length, were placed upon the water, the thickness varied with the length, as it ought to do."

These quotations will serve as examples of the way in which Sir William Bragg deals with his subjects. The first chapter, on atoms, is very clear and easily understood; the last chapters, on crystals, are rather stiffer, but the reader is led on gently from the simpler to the more abstruse.

### GUY'S HOSPITAL REPORTS.

THE first number of the seventy-fifth volume<sup>5</sup> of the *Guy's Hospital Reports* opens with the sermon preached by the Bishop of Oxford in St. Saviour's Cathedral, Southwark, at the commemoration, on January 6th last, of the bicentenary of the hospital, and contains two full-page plates—a fine engraving by Bartolozzi of the tomb of Thomas Guy in the hospital chapel and a drawing of the hospital on January 6th, 1925, by Mr. Hanslip Fletcher. There is a full and sympathetic memoir of the late Dr. Lauriston E. Shaw by Dr. John Fawcett, illustrated by a full-page photograph and by Stanley Cook's kindly caricature of "Laurie" from the *Guyoscope* (1897); it contains extracts from the obituary notice of this active member of the British Medical Association which appeared in our columns (1924, i, 40). Of the thirteen articles dealing with professional subjects two are by the indefatigable editor, Dr. A. F. Hurst, and seven others are on subjects dealing with the alimentary canal, and it may be suspected, even when not so stated, due to his inspiration. There are three articles on ulcerative colitis; Dr. Cyrus Ive analyses six cases, four of which were treated by the Lister Institute's multivalent antidyenteric serum; two patients were definitely improved, though none were dramatic cures. Dr. J. F. Venables records a case of recovery with a stricture of the pelvic colon, a very rare sequel of sporadic ulcerative colitis. In the third article on this disease, which owes so much to Guy's physicians, Dr. A. F. Hurst

<sup>3</sup> *Growth*. By G. R. de Beer, B.A., D.Sc., F.L.S. London: E. Arnold and Co. 1924. (Demy 8vo, pp. viii + 120; 33 figures, 7 plates. 6s. 6d. net.)

<sup>4</sup> *Concerning the Nature of Things*. Six lectures delivered at the Royal Institution. By Sir William Bragg, K.B.E., D.Sc., F.R.S. London: G. Bell and Sons, Ltd. 1925. (Cr. 8vo, pp. xii + 232; 32 plates, 56 figures. 7s. 6d. net.)

<sup>5</sup> *Guy's Hospital Reports*, vol. 75 (vol. 5, fourth series), No. 1, January, 1925. Edited by A. F. Hurst, M.D. London: Wakley and Son (1912), Ltd. 1925. (Med. 8vo, pp. 123; 3 plates, 9 figures, 9 charts. Subscription £2 2s. for volume of four parts; single numbers 12s. 6d. each.)

brings forward evidence in favour of the conclusion that medical is more successful than surgical treatment; among 118 cases treated surgically the mortality was 24.6 per cent., whereas none of his thirteen cases treated medically proved fatal. Dr. R. N. Gauz of Harvard contributes a note on the importance of the presence of leucocytes in the "resting" gastric juice, and Drs. K. D. Fairley and Cyrus Iye find that neutral red, after intramuscular or intravenous injection, is so irregularly excreted into the stomach that it is not of any value as a clinical test. Mr. G. G. Exner and Dr. Cyrus Iye report a case of very severe anaemia, secondary to dental sepsis, successfully treated by removal of all infective foci, early administration of a vaccine of a haemolytic *Streptococcus longus*, and transfusion of defibrinated blood from a donor, who four hours before had been inoculated with the vaccine. Mr. W. H. Ogilvie's paper on the surgical aspects of gall-stone disease contains a number of original observations; he finds that the gall bladder is entirely lacking in temperature sensation and in sensibility to light touch; he also localizes the pain due to its distension; in addition a number of experiments with injections of inert particles were undertaken in order to elucidate the problem of infection of the gall bladder. Mr. R. P. Rowlands writes vigorously on the waste of life from appendicitis, which in England and Wales is responsible for 3,000 deaths a year, mostly in the young. The treatment of asthma at Mont-Dore is described from personal experience by Dr. A. F. Hurst, who attaches considerable importance to its psychological atmosphere as well as the ordinary methods of the cure; in an appended note on four other spas in Auvergne he repeats the dictum that more cases are caused than cured by Plombières treatment. A case of rheumatoid arthritis of dental origin, in which the teeth appeared superficially normal, is related by J. N. A. as a medical autobiography. Massage and remedial exercise in disease of the circulation by Dr. G. H. Hunt is the first of a series of articles dealing with physiotherapy. Dr. Geoffrey Marshall describes the circulatory changes in wounded soldiers, with special reference to the influence of drugs used for the production of anaesthesia, and Dr. Maurice Shaw gives an account of a new technique for the Sigma reaction.

#### NOTES ON BOOKS.

A LITTLE book by Mr. R. T. HUGHES, *Hints on Notemaking*,<sup>6</sup> might advantageously be studied by medical students. Considering the amount of time that is wasted by students in taking notes most teachers probably would advise an abolition of the habit. A certain degree of experience is needed before the nature and value of notes can be appreciated, and this the student does not possess. The matter can, however, be put in a nutshell: In the early stages of his career the student, in his observation of facts, is dependent on his teachers and textbooks for the correctness of his ideas on the subjects of study; they are his mental controls. As he advances in his course he gradually becomes independent of these leading strings and is able to trust his own faculties in the observation of facts, and it is only when this stage is reached that his notes come to be of value. Henceforward the teaching of his mentors and textbooks can be gradually discarded and replaced by his own observations. Notes now become absolutely essential, for it is only by their aid that he can hope to recall and retain the impressions of the innumerable facts that he receives in the course of months and years. Most students fail to take notes of this kind; they cram textbooks and students' aids so called—mere words and printer's ink. The right and necessary use of textbooks at this stage is to enable students to compare their own observations with those of others, to correct their observations with the assistance of better authorities than themselves, and to gain information on subjects that have not come under their notice.

Dr. GUBB of Algiers has compiled a *Questionnaire Médical*, English-French-Arabic, and has added a list of organs, of numbers, and of times of the day or week. The Arab phrases are printed in roman type and appear to be given in the local dialect. Copies of the pamphlet can, we are informed, be obtained free of charge from Nestlé's Milk Company, Rue Charras, Algiers.

The spirit of the medicine of the age is illustrated by the titles of the current textbooks; a few years ago the two large volumes on *Endocrinology and Metabolism*, edited by Professor Lewellys Barker of Baltimore and others, were reviewed in our columns (BRITISH MEDICAL JOURNAL, 1922, vol. ii, p. 873), and since then Professor A. W. HEWLETT of the Stanford Medical School has brought out a volume of more than seven hundred pages which is the second edition of his work entitled *Pathological Physiology of Internal Diseases: Functional Pathology*.<sup>7</sup> It gives a clear and readable account of the present state of knowledge, and has been thoroughly revised and added to since the first edition appeared in 1916. This applies especially to the accounts of cardiac irregularities, cyanosis, the metabolic rate, which has attracted so much attention in America, vitamins, protein hypersensitiveness, endocrine diseases, and the functional aspects of organic diseases of the nervous system. It is a useful and valuable source of reference.

<sup>7</sup> *Pathological Physiology of Internal Diseases: Functional Pathology*. By Alphonse Walter Hewlett, M.D., B.S. New York and London: D. Appleton and Co. 1923. (Roy. 8vo, pp. xxxi + 765; 101 figures. 35s. net.)

#### INCOME TAX: EXPENSES INCURRED BY SALARIED OFFICIALS.

A CASE, *Simpson v. Tate*, which is of considerable interest to professional men holding salaried appointments, was decided in the King's Bench Division recently. Dr. John Tate, County Medical Officer, Middlesex, had claimed, and had been allowed by the local commissioners of taxes, expenses representing the cost of membership of certain professional societies. The revenue authorities appealed against the decision of the commissioners, and a statement of the facts was furnished for the basis of the legal arguments. Briefly, the statement set out that Dr. Tate was not required as a condition of his appointment to be a member of the societies, but that through his membership he received information, in periodical or other form, which enabled him to perform his duties with increased efficiency, and which in the main would not otherwise have been available to him. Dr. Tate's income was assessable, as arising from an employment, under Schedule E, and the rule under discussion, therefore, was that which authorizes the deduction of sums expended "wholly, exclusively, and necessarily in the performance of the duties of the office." That rule has already been examined in the courts on previous occasions, mainly in connexion with claims to deduct travelling expenses, and, following the general trend of those cases, Mr. Justice Rowlatt decided against Dr. Tate and in favour of the contention of the Crown. He may, however, be said to have carried the principle a step further. That principle may be briefly stated to be that the cost of travelling to the place where the duties—for example, those of a company director or a clerk to justices—are to be performed is a preliminary expense—that is, it is incurred, not in the performance of the duties of the office, but to put the office-holder into the position in which he may begin to perform them. Mr. Justice Rowlatt has now stated that principle in broader terms, holding that expenses incurred in qualifying the office-holder to perform his duties cannot be allowed. This would have been taken for granted as regards the original expense of qualification, representing capital outlay, but now covers "all the expenses involved in keeping a man fit for the work he is doing." That rule is laid down by a judge who has had a large experience in revenue cases, and must presumably be regarded as settled law, though on grounds of equity more than one objection could be urged. Perhaps the strongest is that it accentuates the distinction drawn between the output of a machine and that of a trained mind. The existing difference of treatment is that in the latter case no allowance for "depreciation," the gradual exhaustion of productive power, is made, though the fact, if not the probable duration, of the process is as certain. Perhaps the removal of that difference is impossible on practical grounds, but if the rule now laid down is to be fully applied the mental equipment will be deprived not only of a depreciation allowance, but also of the allowances for current expenses of maintaining efficiency. When the "earned income relief" was introduced into the system in 1907, it was represented as to some extent rectifying the

<sup>6</sup> *Hints on Notemaking in Science and Mathematics for Students and Teachers*. By R. T. Hughes, M.A. London: G. Bell and Sons, Ltd. 1925. (Double sup. roy. 32mo, pp. 132. 2s. 6d. net.)

absence of any "exhaustion" allowance; at that time it represented a 25 per cent. reduction on the full rate, whereas now the difference is 10 per cent., and the present moment seems, therefore, to be a particularly unfortunate one at which to stiffen the regulations against the brain worker. In such a case as Dr. Tato's, however, the remedy appears to lie in the hands of the employing authority to some extent. In so far as the information to be derived from the societies is desirable for the proper carrying out of their officer's duties, it would seem only reasonable that the authority should pay the expense of obtaining it—even if, in practice, it is found that the best means of doing so is to pay their officer's membership subscriptions.

## *Nova et Vetera.*

### SOME OLD MEDICAL BOOKS.

A FURTHER instalment of the famous Britwell Court Library is announced for dispersal by Messrs. Sotheby day by day from March 23rd to April 3rd. It has been supposed that this would complete the realization, which has been going on for some years, but the catalogue is silent on this point, so there may yet be further portions to be sold at auction. The section to be dealt with between March 30th and April 3rd contains mainly early English works on arts and sciences, among which medicine and surgery are well represented. Hospitals are represented by the very rare "Ordre of the Hospital of S. Bartholomewes in West Smythfelde in London," 1552; by a similar volume published exactly a hundred years later; and by a book dealing with St. Bartholomew's, St. Thomas's, Bridewell, and Christ's—a reprint, published at the expense of Samuel Pepys, of the original of 1557. Among the large number of books dealing with medicine it is possible to mention only a few of more exceptional interest or rarity.

There are two copies of William Ward's translation of Alexis of Piedmont's textbook: an imperfect one of 1562, and a better copy of the 1595 issue. Colloid therapists may be interested in Francis Anthony's "Apologie or Defence of a verity heretofore published concerning a medicine called *Avrm Potabile*," first edition, 1616, an exceedingly rare monograph. There are three copies, all slightly different, of a pamphlet published by Robert Wyer, "at the sygne of soynt John Evangelyst, in seynt Martyns parryshe, besyde Charynge Crosse," entitled the "Antidotarius," and dealing with "bawmes, oyles, and wounde drynkes . . . ryle and profitabill for every Surgyan"; all are very rare. From the same publisher there is a translation of Arnold's (of Villa Nova) "Defence of Age," apparently differing from all other copies, and possibly therefore an unrecorded edition. Another choice volume is George Baker's " . . . Oleum Magistrale . . . the which Oyl cureth . . . Wounds, Contusions, Hargubush shot, Cankers, pain of the Raines, Apostumes, Hemerhoids, olde Ulcers . . ." published in the "Pultrie" in 1574.

The study of special subjects seems to have evolved earlier than is sometimes realized; for instance, there is R. Banister's "Treatise of One Hyndred and Thirteene Diseases of the Eyes, and Eye-Liddes," the second edition of which was published in 1622; a copy of this may be seen as Lot 68 in the March 30th sale; and Lot 125 is William Briggs's "Ophthalmographia" (1686), a textbook of ophthalmic anatomy, including the author's new theory of vision. The familiar name of Jenner appears as the compiler (or possibly only the publisher) of a book on invalid cookery dated 1655. Andrew Bordo's "Breviary of Healtthe" is represented by five different editions, the earliest of 1552 and the latest of 1598. First aid, too, is another conception by no means modern, as is shown by Stephen Bradwell's "Helpe for suddain accidents endangering life, by which those that live farre from Physicians or Chirurgions may happily preserve the Life of a poore Friend or Neighbour," the very rare first edition of 1633. William Bullein seems to have been a prolific medical author: four separate treatises are contained in this sale, ranging from 1562 to 1595, and devoted mainly to the prevention of disease; one

of them is the only copy known of the particular book in question. Dr. John Caius is represented by a good copy of the first edition of his "Boko or Counseill against the Disease commonly called the Sweate or Sweatyng Sicknesse"; this also is extremely rare, though it is accessible in a reprint issued by the London Sydenham Society in 1844.

From Wynkyn de Worde's press there is a copy of a medical textbook by Bishop Canutus, published about 1510; the only other copy known is in the Cambridge University Library. William Clowes is represented by three monographs, one on venereal diseases (1585) and two on gunshot wounds (1588 and 1586); and there are three editions of Thomas Cogan's "Haven of Health" (1584, 1589, and 1612). "The Castel of Helth," by Sir Thomas Elyot, is represented in five separate editions, one of them the only copy known. Erasmus of Rotterdam devoted one of his literary efforts to the "praysse and comendation of the most hygh and excellent science of phisicke," as the translator renders it; the only known copy of this translation (of about 1538) is Lot 269 in the April 1st sale.

National Health Insurance practitioners may be interested to know that in 1628 William Folkingham published "Panala Medica . . . the Fruitfull and Frugal Nourse of Sound Health and long Life." The full title of a translation of one of Guy de Chauliac's works is worthy of being set out at length: "The Questyonary of Cyrurgyens, with the formulary of lytell Guydo in Cyrurgie, with the spectacles of Cyrurgyens newly added, with the fourth Boke of the Therapeutike, or Methode curatyfe of Claude Galyen prynce of physiciens, with a Syngular treaty of the cure of vlcers"; the colophon at the end relates that the translation is "out of the Frensshie (at the instigation and costes of the ryght honest parson Henry Dabbe staeyoner and byblyoplyst in Pauls churche yerde) by Robert Coplande of the same faculte," about 1543. Another reminder that there is nothing new under the sun is brought home by Lot 415, Irvino's "Medicina Magnetica: or the rare and wonderful Art of Curing by Sympathy," first edition, 1656; while the interest of the female sex in medicine is exemplified a few items further on in the "Choise Manuall, or Rare and Select Secrets in Physick and Chirurgery," by Elizabeth Talbot, Countess of Kent, second edition, 1653. Another early surgeon of renown is represented in a translation of "Lanfranc of Mylayne his brieve . . . now first published in the Englysho prynto by John Halle Chirurgien. An Historiall Expostulation also against the beastly abusers, both of Chirurgerie and Physicke in our tyme," first edition, 1565.

The subject of diet is often dealt with in these early textbooks, as, for example, in Christopher Langton's "Introduction into Physicke, wyth an vniversal dyet," about 1550. Peter Lowe's "Whole Course of Chirurgerie" (first edition, 1597) is said to be one of about six known copies; correspondence in this JOURNAL some few months ago revealed the whereabouts of several of these, previously not generally known. A valuable rarity is Thomas Moulton's "Mirrour or Glasse of Helth," about 1540, of which but one other copy (and that imperfect) is known to exist; copies of two other editions are also for sale. Another book on first aid is the "Help for the Poor . . ." by Robert Pemel, Physician of Crane-brook in Kent, 1653, described by the auctioneers as exceedingly rare. Thomas Phaer published in 1544 his "Regiment of Lyfe," a treatise mainly on diseases of children, but containing also sections upon the plague; the only copy known of the first edition is one of those now offered, also one of 1553, thought to be of the fourth edition, and another of 1560. An early treatise on helminthology is that of W. Ramsay, 1668, whereof the first edition is represented in this collection. The extremely rare "Urinal of Physick," by Robert Recorde, of which the British Museum possesses the only other extant copy (1547), is dedicated, curiously, to the "Wardens and Company of the Surgions in London," not to the physicians, as might have been expected; including a later edition of this book, there are in all five volumes from the pen of this writer included in the sale.

So far as this collection is concerned, the earliest work devoted to midwifery seems to be that by Thomas Raynold,

1545. The "Regimen Sanitatis" of Salerno is represented in five translations, ranging from 1550 onwards. A very timely production was the monograph on the plague, published by George Thomson, M.D., in 1666, though he seems to have been more eloquent on the symptoms and the *post-mortem* anatomy of the disease than on treatment. No less than five editions are listed of the "Treasure of Poor Men," a medical textbook of unknown authorship, first published about 1526; two of these five are the only copies known of their respective editions, and two more are of the utmost rarity. There are also copies of four editions of Thomas Vicary's "Englisho Man's Treasure," the earliest of which is dated 1586; this book was the subject of careful analysis in the BRITISH MEDICAL JOURNAL of January 25th, 1896, by Dr. J. F. Payne, who showed that it is really a plagiarism of Lanfranc and Henri de Mondeville. Unique save only for a copy in the British Museum is the translation of John of Vigo's "Lytell Practyce of Medecyne," published by Robert Wyer, one of the early sixteenth century printers. Indeed, the vast number of books valuable by reason of being unique or almost so has all along been a feature of the Britwell Court Library; it is still prominent even in these later sections, where one hardly expects to meet so many items of this degree of rarity.

## THE HEALTH OF THE ARMY.

### ANNUAL REPORT FOR 1922.

THE Annual Report on the Health of the Army for the year 1922 has just been issued.<sup>1</sup> It is unusually brief, and the delay in its publication has the effect of making it less much of its interest. It is very desirable that Sir William Leishman should, as he hopes, manage to expedite the publication of future reports during his term of office as Director-General.

In the report under review several details to which we were accustomed in previous reports have been omitted. It would be difficult, for example, from the statistical data provided in it to compare the health of the army in 1922 with other years and other armies, except in a limited degree. There is no reference to climatic conditions in commands abroad, such as Turkey, Iraq, the Rhine and Silesia, Egypt and Palestine, where troops were stationed during the year. But what we miss most is the means of comparing the incidence of sickness and of the more important diseases in 1922 with the years previous to the war, more especially as so much has been done in recent years for the prevention of enteric fever and venereal and malarial diseases. The only comparison of the kind that is possible is found in two of four charts at the end of the volume on invaliding, in connexion with which there has been a remarkable increase in 1921 and 1922. In 1921 the ratio of men discharged from the army as medically unfit was 27.5 per 1,000 of strength, and, in 1922, 19.3 per 1,000. Since the year 1899 the former ratio was only once exceeded, in 1901, and the latter only during the three years of the South African war. From 1903 the ratio had declined steadily to 8 per 1,000 during the three years previous to 1914. The only light thrown on this is in the opening paragraph of the report, where it is stated that there was a gradual elimination of the unfit who were enlisted in the transition period following the war.

As bearing on this, a report by the medical specialist at Netley is quoted, and is significant: 20 per cent. of the cases brought before the medical board there were suffering from tachycardia for which no cause, such as debilitating illnesses or prolonged service abroad, could be found except in a comparatively small number. The suggestion is made that the young man of 18 years of age, who enlisted in 1919 and 1920, was, during the war, at an impressionable age physically and mentally, and lacked parental discipline and control, so that the unwelcome

discipline and irksome regularity of army life induced in his inferior nervous system the syndrome of disordered action of the heart. The majority of these youths broke down if any hard or disagreeable task had to be done. This is scarcely pleasant reading, if the medical specialist's suggestion is a correct explanation of the breakdown.

In the recruiting year, 1921-22, to which the report refers, 29,079, or 375.22 per 1,000, of the recruits examined were rejected and 2,487 discharged within six months of enlistment as medically unfit. The highest number of rejections was 433.63 per 1,000 in the Scottish Command, and the lowest 209.46 per 1,000 in the London District, where the largest number were examined. The great difference between these and other figures is probably due, to some extent at any rate, to less careful selection in some commands than in others of the men sent before the medical officer. Defective vision, under-developed chest, loss or decay of many teeth, and flat-feet were the chief causes of rejection.

The admission rate for sickness in all commands at home and abroad was 515.8 per 1,000 of an average strength of 208,079, and the death rate 3.22, as compared with 649.9 and 4.20 per 1,000 respectively in 1921. The constantly-sick rate was 41.47, as compared with 50.46 in 1921 and 32.21 in 1913, the only comparison made with any year previous to 1921. The admission rate in the United Kingdom was 376.4, and in the large garrisons of India, Egypt and Palestine, the Army of the Rhine, Iraq and Turkey, it varied between 600 and 700 per 1,000 of strength.

The chief cause of admission to hospital was venereal disease, with a ratio of 70.7 per 1,000 of strength. The rate was exceptionally high, 254.2 per 1,000, in the Army of the Rhine, where licensed brothels were put out of bounds and other extensive prophylactic measures enforced. The only other rates above 100 were 125.2 in Gibraltar, 103.6 in Malta, and 113.4 in Egypt and Palestine. The Indian rate was 84.7 and the home rate 35.4. A marked decrease is shown in the incidence of syphilis.

The next greatest cause of admission to hospital was malaria, with a rate of 65 per 1,000 of strength. Except in the small European garrison of West Africa, where the admissions for malaria amounted to 582 per 1,000 of strength, the only other rates in excess of 100 were 175.4 in India and 120.9 in South China. Very little inefficiency was caused by the enteric group of fevers, the highest admission rate being 6.3 per 1,000 in Iraq. In India it was 3 per 1,000. Unfortunately there is little or nothing said in the report about these diseases, nor any indication of the percentage of men protected by prophylactic vaccines. No other group of diseases calls for special mention.

Short summaries and statistics are given under the heading of each command. A section of the report deals with the work of the dental department, and other sections are allotted to the work of the directorates of hygiene and pathology.

### A MILK OUTBREAK OF PARATYPHOID FEVER.

THE Ministry of Health has issued a report<sup>1</sup> of an outbreak of milk-borne paratyphoid, by Dr. W. V. Shaw. The report is prefaced by a note by the Chief Medical Officer, Sir George Newman. The epidemic comprised 52 cases, of which 2 ended fatally. In the two weeks ended October 4th, 1924, 31 cases of enteric were notified to the Ministry by the borough medical officer, and Dr. Shaw began investigation on October 7th. Up to October 22nd 21 more cases were notified, making the total of 52 above stated. After considering and excluding other possible causes of spread, attention was concentrated on the milk supply, which was quickly proved to be responsible. The organism was *Bacillus paratyphosus* B, and the outbreak had the explosive character typical of spread by a specifically infected article of food consumed by many persons. The cases were all within the area of one milk vendor, who

<sup>1</sup> Report on the Health of the Army for the Year 1922. Volume Ivii. London: H.M. Stationery Office. (8vo, pp. iv + 105; with 4 charts. Price 3s., purchasable at H.M. Stationery Office, Adastral House, Kingsway, London, in Manchester, Cardiff, Edinburgh, and through any bookseller.)

<sup>1</sup> Report on an Outbreak of Paratyphoid Fever in the Borough of Chorley. By W. V. Shaw, O.B.E., M.D. (Report No. 30.) H.M. Stationery Office. 2d. net.

obtained his supply from eight farms outside the borough, the milk from all of them being mixed before distribution. Instead of following in detail Dr. Shaw's convincing story of his tracing of the source, it will make for brevity to state that of eight members of the household at the incuolated farm it was ultimately found that only three had escaped attack. A case of enteric fever was notified from the farm to the medical officer of health of the rural district on August 7th. He was off duty for a few days, but the acting medical officer visited on August 7th and consented to the child being nursed at home, though accommodation was available at the isolation hospital. A trained nurse was employed, her work being supplemented by two members of the household, who were also engaged on ordinary domestic duties. The milk probably became infected about the end of August. The farmer himself, who was stated to be feeble-minded and uncleanly, with clothing soiled at times with faecal matter, was definitely out of sorts with fever and diarrhoea at the beginning of September, but continued milking all through September until removed to hospital on October 7th. Certain other members of the household had similar symptoms a little later. The water supply, from a local spring, was poor in quantity, and there was no water equipment such as a milk farm ought to have, nor for due attention domestically to the cleansing of infected clothing. The farm had no dairy for storage of milk.

Concerning the action of the medical officers, Sir George Newman writes thus in his prefatory note:

"In the circumstances described by Dr. Shaw, specific infection of the milk at the farm was almost inevitable. The patient was, nevertheless, permitted to remain at home throughout the course of her illness, without any supervision on the part of officers of the local authority. No official inquiry was made to ascertain whether adequate isolation of the patient was being maintained or whether secondary cases had occurred among other members of the household.

"In brief, the mistakes in administrative procedure made in connexion with this outbreak may be summarized as follows:

1. The acting medical officer of health, who visited the farm on August 7th, did not remove the patient to hospital.

2. He did not revisit the farm to satisfy himself that his instructions regarding the isolation of the patient and disinfection of excreta, etc., were being carried out.

3. The medical officer of health, who resumed duty on August 11th, did not appreciate his responsibilities in the matter and did not visit the farm till October 1st.

4. Thus after the first visit there was a period of complete disregard between August 7th and October 1st, during which no restrictions were placed upon the milk supply. On the latter date the medical officer of health of the borough visited the farm accompanied by the medical officer of health of the rural district, because by that time suspicion had been aroused that milk from the farm was the vehicle by means of which infection was being spread in the borough.

"The facts recorded in this report emphasize the necessity for constant vigilance on the part of the officers of sanitary authorities when dealing with even an isolated case of infectious disease. In the present instance, an extensive outbreak of paratyphoid fever was caused by failure on the part of the responsible officer concerned to appreciate the danger inseparable from the retention at a dairy farm of a case of that disease.

"The importance of prompt and continuous attention being exercised by medical officers of health on the occurrence of cases of infectious disease among persons engaged in occupations associated with the production and distribution of food and milk is demonstrated by this outbreak. Neglect to take the most ordinary precautionary measures led to disaster, and I trust that the lessons to be derived from the facts recorded by Dr. Shaw will not be lost upon local authorities and others responsible for the maintenance of the public health."

This outbreak is referred to in the article on local government in rural districts at page 565 of our present issue.

## RUTHERFORD MORISON TESTIMONIAL.

THE following is the second list of subscriptions to this fund, particulars of which were published in our issue of January 17th (p. 138). The amount received up to March 13th was £1,143 7s. The committee has decided to close the fund on March 31st; until that date subscriptions can be sent to the Honorary Secretary and Treasurer, Mr. R. J. Willan, M.V.O., M.S., F.R.C.S., 6, Kensington Terrace, Newcastle-upon-Tyne.

### SECOND SUBSCRIPTION LIST.

£25.—Mr. W. G. Richardson (Kewick), Mr. S. S. Whillis (Newcastle).  
£10 10s.—Dr. J. J. Campbell (Newcastle), Dr. J. Charles (Stanley), Mr. J. Clay (Newcastle), Dr. W. S. Dickie (Middlesbrough), Dr. A. Duke (Newcastle), Mr. O. W. M. Hope (London), Lieut.-Colonel A. H. Procter (Darjeeling), Dr. Fred. Proud (Newcastle), Mr. S. Raw (Sunderland), Dr. W. L. Ruxton (Newcastle), Mrs. Balgout and Hutchinson (Northallerton).  
£8.—Dr. G. W. Pallthorpe (London).  
£5 5s.—Dr. H. H. Altholson (Wallsend), Dr. J. Anderson (Scotlan Delaval), Dr. W. D. Arnison (Newcastle), Dr. Badcock (Carnhill-on-Tweed), Dr. J. Berry (London), Dr. H. S. G. Boswell (Ladysmith, Natal), Dr. Campbell (Sldmouth), Professor H. Horsley Drummond (Newcastle), Dr. J. C. Hamilton (Scribston), Dr. N. Hodgson (Newcastle), Dr. J. A. McLeod (Alnwick), Dr. S. D. McKeefe (Newcastle), Dr. H. B. Ord (South Shields), Dr. H. W. T. Russell (Trimdon Station), Dr. T. Russell (Trimdon Grange), Dr. W. Seymour (Newcastle), Dr. J. S. Taylor (Vryheid, Natal), Dr. R. Walker (Wooler), Dr. R. J. Weldner (North Shields), Dr. J. Whyte (South Shields), Surgeon Commander F. G. Wilson, R.N.  
£5.—Dr. E. Davison-Smith (Whickham), Dr. Ruth Nicholson (Liverpool), Mr. A. S. Percival (Newcastle—second donation), Dr. Olive Wilson (Newcastle).  
£5 5s.—Dr. N. R. Beattie (Walker Gate), Dr. E. O. Bralhtwalte (Warri, Nigeria), Dr. H. P. Benn (Censham), Dr. A. J. Dr. A. Fairlie (Shields), Dr. S. Dr. E. Farquhar (G. R. Newsome Ramsay (Beckars Margate), Dr. J. Swenberg  
M. A. Archdale (Ashington), Dr. H. Hartlepool, Dr. H. Crichton (T. Dixon 122 Fairweather Hewlson (Newcastle), Dr. Lillie  
J. Leishman (Barnard Castle), Dr. J. Macfadyen (Newcastle), Dr. D. R. MacGregor (Wallsend), Dr. McCullagh (Bishop Auckland), Dr. T. W. Maddison (London), Dr. W. Martin (Newcastle), Mr. D. M. Millar (Pelling), Dr. I. M. Pirrie (Maldon), Dr. E. Pirrie (Maldon), Dr. F. W. Ramsay (Bournemouth), Dr. E. Ranken (Sunderland), Dr. N. R. Rawson (Witley Bay), Dr. D. R. Roberts (New Tredegar), Dr. R. Sanderson (Maryport), Dr. A. E. Bernard Shaw (Newcastle), Dr. Sparks (Whitby Bay), Dr. F. S. Walker (Newcastle), Dr. N. B. Walley (Dudley), Dr. G. S. Woodman (Baghdad), Mr. O. Hamilton Whiteford (Plymouth).  
£2.—Dr. S. Louise Rook (Bradford), Dr. L. H. Walker (Dinnington), Dr. Edith S. Williamson (Newcastle).  
£1 1s.—Dr. E. O. Abraham (Wolston), Dr. A. Angus (Tynemouth), Dr. F. Barron (Barnard Castle), Dr. J. I. Blandford (Hewick), Dr. H. O. Broadhurst (Barnard Castle), Dr. J. M. Braithwaite (H.M.S. Valiant), Dr. J. F. Bridge (Leamington Spa), Dr. J. Ferens Colman (Newcastle), Dr. Corbett (Hove), Dr. Cowpen, Dr. O. P. Fairlie (Newcastle), Dr. W. Gibbons (Gateshead), Dr. J. E. Goffton (Stanhope), Dr. Barbara N. Grinling (Hewlson), Dr. Helen Gurney (Newcastle), Dr. S. He (Sunderland), Dr. C. J. Henderson (Barnard Castle), Dr. R. S. Hindmarch (Barnard Castle), Dr. R. Hunter (Barnard Castle), Dr. Kendall (Brixton), Dr. H. Kerr (Colliery), Dr. F. S. Leach (Colliery), Dr. D. J. Lewis (Machynallath), Dr. W. G. Lidderdale (Cheltenham), Dr. McCull (Pruboe), Dr. J. R. (Blackhill), Dr. Mackenzie (Colliery), Dr. A. Martin (Tunbridge Wells), Dr. F. W. Melvin (Oswestry), Dr. Jean M. Morden (Nottingham), Dr. S. E. Murray (Leicester), Dr. H. Newsome (Pill), Dr. D. F. O'Kell (Baldon Colliery), Dr. MacRae and Raine (Corbridge), Dr. S. Phillips-Bedson (London), Dr. T. Price Poole (West-cliff-on-Sea), Dr. Smallwood (Gateshead), Dr. A. Smith (Swallow), Dr. J. L. Spiers (Gateshead), Major T. W. Stallybass (Hounslow), Dr. Russell Steele (London), Dr. J. B. Tigbo (Stannington), Dr. Dorothea M. Tudor (Leamington Spa), Dr. W. A. Tweddle (Newcastle), Dr. W. Vincent (Sheffield), Dr. Olivia N. Walker (Plymouth), Dr. G. W. Weir (South Shields), Dr. J. Whillis (Gosforth), Dr. A. F. Wilkin (Farm-on-Tees), Dr. H. A. Wilson (Newcastle), Dr. W. Q. Wood (Edinburgh).  
£2.—Dr. Sollman (Birmingham).  
£2.—Dr. Christina Barrowman (Newcastle), Dr. R. E. Brown (Willington), Dr. Craig (Dudley), Dr. Dr. T. M. Kimpster (Gateshead), Dr. N. O. L. (Middlesbrough), Dr. W. H. Mallow (Hill), Dr. M. H. Munro (Nettleworth), Dr. E. J. Scoresby-Jackson (London), Dr. W. 10s.—Dr. Florence B. Lambert (London), Dr. J. W. Sandoe (Broad Clyst).  
£5.—O. F. D. H.  
Subscriptions promised, but amounts not specified: Dr. Modlin (Sunderland), Dr. Norris (Gateshead), Dr. W. Smith (Gateshead).

# British Medical Journal.

SATURDAY, MARCH 21st, 1925.

## LOCAL GOVERNMENT IN RURAL DISTRICTS.

ELSEWHERE in this issue (p. 563) will be found a note of a remarkable report by Dr. W. V. Shaw, a medical officer of the Ministry of Health, concerning an outbreak of paratyphoid fever in a borough in Lancashire. The outbreak is clearly traced by Dr. Shaw to a milk farm in the adjoining rural district. The facts as to mismanagement of the infection at its source speak so loudly as to need no emphasizing. Suffice it to say that the article in the *BRITISH MEDICAL JOURNAL* of August 30th, 1924 (p. 377), on the conquest of enteric fever could never have been written if the average health administration throughout England were on anything like so low a level as it appears to have been in this particular instance and at this particular time in the rural district in question. But our present purpose is not to animadvert on the deplorable occurrence; the terms of Sir George Newman's prefatory note need no supplementing.

In concluding his note the Chief Medical Officer of the Ministry says that he trusts the lesson to be learned from the facts recorded by Dr. Shaw will not be lost upon local authorities. If that means that risk really exists of similar administrative failure in other rural districts (the possibility in boroughs seems almost inconceivable in the present day), then what Dr. Shaw has written should definitely be brought under the notice of the Royal Commission on Local Government. The report of that body is being looked forward to with much interest by all parties concerned. Presumably it will deal with the whole subject of the suitability for their work of the several classes of local health authorities in England—those in control of great cities, of county boroughs, of ordinary municipal boroughs, of urban districts, and of rural districts.

An important question certainly ought to be whether the last named group, or even the last two groups, are so constituted and administered as to afford adequate protection against invasion by infectious disease, not only of their own populations, but of neighbouring communities. A mutual obligation rests on them whether they be large or small, and the question is whether the obligation is being duly fulfilled. There are in England and Wales 663 rural districts, with an extraordinary range of population—from a few hundreds up to 76,000. Eleven of them have less than a thousand inhabitants; of districts between one and five thousand there are 117; between five and ten thousand 209; between ten and twenty thousand 370; and so on to the top of the scale, where five have between 50,000 and 76,000 inhabitants. Urban districts vary similarly. Their total is 784, and the populations range from under 1,000 to over 165,000. Thus we have the absurdity that one so-called "urban" district has under 1,000 people, and another so-called "rural" district has over 76,000.

The fact that a rural district can, if the Ministry of Health approves an application to that effect, obtain urban powers does not concern us here, but the anomalies just indicated will doubtless receive attention from the Royal Commission. What may be the smallest unit of population which can be normally relied on to furnish reasonably efficient local govern-

ment in respect of public health demands consideration. Each rural and urban district, even if merely a village, has laid on its shoulders responsibility for routine administration of the Public Health Acts. But in the whole sphere of health preservation and disease control no local authority can live to itself. Indeed, it is permissible to inquire here whether there may not be a risk of neglect, alike in town and country, of this duty of mutual protection, owing to modern developments of the health work of local authorities within their own areas. Is it not possible that an officer may get so much absorbed in "welfare" work of all sorts, in respect of mothers and infants and school children, and so forth, as to be less alert in what were his primary functions a generation ago? We have no knowledge of what is done in the new directions in the rural district to which Dr. Shaw's report refers, but the general query can do no harm, and if it is everywhere needless that is all the better.

The city has a duty to endeavour to prevent invasion of the country around it by infectious disease, and the country has its duty to the town, as exemplified in its supervision and control of milk supplied for urban use. That, as it happens, is the particular question which emerges from Dr. Shaw's report. But there is no profit in dwelling on individual errors. A rural district of even 20,000 inhabitants cannot usually be expected to pay for the whole time of a medical officer of health, and, if it must make provision for itself, may have no choice but to accept such services as can be rendered by a general practitioner with or without a special diploma. In these days it can only be a man of quite exceptional capacity who finds himself able to maintain a working knowledge of the continued advances in medicine, surgery, and midwifery, and at the same time perform the ever-widening functions of a health officer. It is the system which is at fault, and we must wait for Lord Onslow's Royal Commission to submit proposals for the remedy of existing defects at the same time that it has regard to the case of those medical men who, under conditions for which they are not responsible, have struggled hitherto to carry the double burden of public health work and private practice.

## DUST SAMPLING IN SOUTH AFRICAN MINES.

GOLD-MINING on the Witwatersrand has always been a dangerous trade, with its own occupational disease. In 1912 a commission reported that 32 per cent. of a group of 3,136 miners examined were affected by silicosis or tuberculosis-with-silicosis. Conditions appeared to have improved greatly by 1917, when out of 14,625 miners examined only 5.9 per cent. were found to be the subjects of tuberculo-silicosis. The report for the year ending July 31st, 1923, showed that the proportion had fallen to 3.07 per cent. The diminution in the amount of silicosis has gone hand in hand with diminution of the dust content of the air, for during recent years an intensive campaign against dust has been waged, because it has been proved that the particles of metallic dust created by the drilling machines damage the lungs and pave the way for tuberculosis.

Since silicosis has a latent period of several years before it manifests itself by any clinical signs, the data available at present do not afford any information as to whether or not fresh cases of silico-tuberculosis are arising; the cases now developing may all have been produced by conditions no longer obtaining. A further

period of years will have to pass before it can be decided whether the steps which have been taken to avoid the inhalation of metallic dust are adequate or not; but in the meantime it is important that a careful study should be made of the atmospheric conditions in the mines and the amount of dust in the air accurately registered. All these questions are gone into very fully by Dr. A. Mavrogordato in a report published by the South African Institute for Medical Research.<sup>1</sup> Different methods for dust sampling are in use in different parts of the world, and several of these methods are described by Dr. Mavrogordato, but he devotes most of his report to the instrument known as the konimeter, which seems to be in general use in the mines of the Witwatersrand. His experiments will be of considerable interest to sanitarians who are studying methods of measuring atmospheric dust in factories and workshops in this country, although their problems may not be identical with those which face the health officer in the gold-mining districts of South Africa.

Apart from the technical details of dust-sampling tests, two observations made by Dr. Mavrogordato in his report deserve special notice. The pathological changes grouped under the term "silicosis" do not occur apart from the presence of visible particles of dust in the tissue, or, to speak more exactly, particles visible under the microscope. The smaller ultra-microscopic particles, which, of course, are much more plentiful in the air, do not appear to be injurious to the lungs in the same way as the larger particles. Probably the lungs behave in a similar way to ordinary filters, and only retain particles above a certain size, allowing smaller particles to escape. The minimum size of particles likely to be retained is about half a micron, which, curiously, is about the size of the smallest pathogenic bacteria.

The other observation to which we wish to call attention is the question of using captive animals for the purpose of recording the dust concentration of the atmosphere. Although it appears that, in the hands of experts, the various dust-sampling instruments give a reliable record of atmospheric dust, yet reading such a report as this the question naturally arises whether we are in possession of sufficient knowledge of the effects of dust on the lungs to be able to interpret these konimeter findings, and to say, for instance, that more than a certain amount of dust is dangerous and a less quantity to be disregarded. To ask this question does not mean that we fail to appreciate the value of the figures supplied by dust samplers: it is obvious that where health is at stake the most accurate records must be kept of the atmospheric conditions in such a dangerous occupation as gold-mining. But it will take many years before the figures of the dust sampler can be correlated with the incidence of silicosis, and in the meanwhile it would seem that a much quicker way of judging of the potential danger of the atmosphere would be to keep guinea-pigs or rats in cages in the mines, and to compare the duration of life underground with the duration of life above ground, and to study the particular conditions under which such captive animals most quickly develop silicosis. Dr. Mavrogordato states that some such tests are being carried out in South African mines, the animals being used for testing atmospheric conditions in the same way that mice and small birds are used in collieries and in submarines.

#### ACQUITTED—BUT FINED.

WE invite the attention of all members of the profession, whether on the panel or not—as the *Times* has invited the attention of all citizens, whether members of the profession or not—to the proceedings under the Insurance Acts reported in the SUPPLEMENT of this week (p. 122) under the title "A fatal case of diphtheria." The London Insurance Committee brought a charge of gross negligence against Dr. Z in failing to diagnose diphtheria. The Inquiry Committee found that the accused person was not negligent but attentive, that at most the accused committed an error of judgement in not recognizing before he did the supervention of diphtheria in a complicated case of tonsillitis and Vincent's angina, that the machinery which involved the inquiry should never have been put in motion, and that the respondent should receive his taxed costs. The Ministry of Health agrees that he should receive his costs, but considers that he ought to be fined £20. A similar course was taken by the Ministry in regard to the inquiry into a fatal case of appendicitis reported last week (SUPPLEMENT, p. 100). There the Ministry made no order as to costs, but imposed a fine of £10 upon the practitioner. In that case, however, the Committee of Inquiry, while finding that the charge of negligence put forward failed, expressed the view that the complainants were justified in making the representation which led to the inquiry. In transmitting the documents in the case of diphtheria upon which the report on page 122 of the SUPPLEMENT for this week is founded, the Ministry requested us to publish the text of the letter it had addressed to the London Insurance Committee, and with a slight modification, in order to omit the name of the practitioner, this has been done. In that letter it will be observed that the Minister states that he was advised that some of the symptoms from which the patient suffered should have suggested the presence of diphtheria. It is not stated by whom this advice was tendered; it does not seem to be in accord with that tendered by the Committee of Inquiry. Mr. Neville Chamberlain only came into office at about the time the proceedings were instituted, but he is technically responsible, and we shall be happy to receive from him or from any responsible representative of the Ministry any further explanations they wish to offer, and shall be prepared to publish them if of reasonable length.

#### ADDITIONS TO THE POISON SCHEDULE.

THE regulations governing the sale of dangerous poisons to the public were modified in 1908 by an Act of Parliament which relaxed the stringency of the previous law. That Act permitted traders other than chemists to hold a licence for the sale of arsenical and other poisonous preparations used in agriculture and horticulture, such as sheep-dips, insecticides, and weed-killers. It was not necessary that the licensee holder should keep a poison book for the entry of the sale and of the signature of the buyer as a chemist had to do for poisons named in Part I of the schedule. An anomaly was thus created: the restrictive term in the schedule which had formerly read "arsenic and its preparations" now became "arsenic and its medicinal preparations." Thus, except under a physician's prescription, anyone buying a medicinal preparation containing arsenic must be a person known to the seller or introduced by someone known to the seller, and he must sign the poison book; but if he wanted arsenical weed-killer he could get half a hundredweight by an order on the telephone. The danger underlying this freedom was brought prominently to notice in a trial for murder by poisoning with arsenic obtained as weed-killer some two or three years ago. Resolutions were submitted to the Privy Council by the Pharmaceutical Society proposing amendment of the poison schedule in respect of this and other matters. Approval

<sup>1</sup> *The Value of the Konimeter. Being an Investigation into the Methods and Results of Dust-Sampling as at Present Practised in the Mines of the Witwatersrand.* By A. Mavrogordato, M.A., M.R.C.S., L.R.C.P. Publications of the South African Institute for Medical Research, Johannesburg; No. XVII. (Cr. 4to, pp. 71; 23 figures. 5s.)

of the resolutions submitted has been signified by an Order in Council dated February 26th, 1925. Under this order the limiting word "medicinal" again disappears from the text, and the poison book must now be signed for all purchases of material containing arsenic. Nicotine and tobacco extracts which are used as insecticides will be included in the same group as arsenic. The word "vegetable" is deleted from the text of "poisonous vegetable alkaloids." By this amendment substitutes for cocaine and other synthetic alkaloids are brought into the schedule. The active principles of digitalis and strophanthus, not being alkaloids, were not previously included with other vegetable principles among the potent articles forming Part I, where they rightly belong; these have now been added to the list. Cannabis indica has now been made a scheduled poison for the first time, and has been grouped in Part I. This was done because information was received indicating that its use as an intoxicant was spreading in this country. The word "coea" is now deleted from that provision which exempted from the regulations weak preparations containing, like some coca wines, less than 0.1 per cent. of the alkaloids. Any preparation of coea is now a poison within the meaning of the Act. Barium salts, except barium sulphate, have been added to Part II of the schedule. Poisons named in Part II may be bought without any restriction on the buyer; the only restrictions on the sale are that they must be labelled with the word "poison" and the name and address of the seller, and can only be sold by registered chemists. Barium carbonate has been introduced as a rat poison, and there have been fatal cases of poisoning from barium salts given in error. It thus became necessary to provide for the proper control of barium compounds. There would seem, however, to be a danger in exempting barium sulphate from these provisions of the Act, for it has been used as a preliminary meal for x-ray photography, and it is only non-poisonous when highly purified.

#### DIFFICULT CHILDREN—AND A PHILOSOPHER.

THE social evening at the Royal Society of Medicine on Monday last was attended by a large and distinguished company, who were received by the President, Sir StClair Thomson, in the library, where various objects of interest were exhibited. Later on Dr. H. C. Cameron gave a brief address on John Locke, the philosopher, and his views on the upbringing of children. Many parents, said Dr. Cameron, must have experienced painfully the contrariness of children—how, shepherded in one direction, they stampeded in another; how for the parent to insist was only to arouse new forces of resistance, and for him to forbid was only to provoke the spirit of disobedience. Harassed parents of the twentieth century might do worse than consult the philosopher of the seventeenth, who found time to dip his quill in the inkhorn and put on paper a picture of the child for all time. There could scarcely have been another member of the medical profession, said Dr. Cameron, who came near to Locke in his combination of philosophy and skill in practical affairs. It was Locke who restored the finances of the country after the Revolution; it was he who played a great part in the foundation of the Bank of England; it was he who introduced permanent and striking reforms in what would now be called Poor Law administration; it was he who was largely responsible for drawing up the charter for the new colony of Carolina. Probably it was his medicine which gave his philosophic mind its practical bent. His association with medicine was not merely preparatory to other and greater work, but he was throughout an ardent practitioner, and intimate with Sydenham. For many years the famous Lord Ashley, afterwards first Earl of Shaftesbury and Lord Chancellor, was his patient. Ashley had been tortured by

a painful abdominal swelling, and in 1668 the all-seeing Pepys wrote that he heard "my Lord Ashley was going to have his body cut into"—in other words, Locke had determined to act. The lecturer described how Locko operated for hydatid cyst and kept the wound open by means of a silver tube, which tube had to be worn permanently, and in the scurrilous political literature of the time took the place occupied in a later day by Mr. Gladstone's tree-felling exploits or Mr. MacDonald's motor car, as a subject on which the poorest wit of the opposite faction could feel moderately sure of raising a laugh. When such a man as Locke—philosopher, political economist, financier, physician, and, apparently, no mean surgeon—turned to the study of the child the result was bound to be interesting. His ideas, invested with the genius of Rousseau, reappeared in the Frenchman's famous *Emile*. Locke's writing was cold and devoid of feeling; Rousseau's was disfigured by straining after paradox, but it pulsated with fire and enthusiasm as he proclaimed the ministry of the schoolroom to be as sacred as the ministry of the altar. But it was to Locke and not to Rousseau that those who found their children a little difficult to-day should turn for guidance. Locke tackled the difficulty of the crying child—the child with what he called the "stomachful cry," the cry intended to disturb and distress the parent. Locke saw that parents whose children cried were nearly always parents most distressed by crying children, and least able to hide from the children the fact that they were distressed. It was astonishing, said Dr. Cameron, with what certainty the child divined the weak point in its mother's heart and exploited its advantage. Much childish wickedness, said Dr. Cameron, was designed by the culprit to produce the maximum emotional response having regard to the character of the mother, nurse, or whoever had charge of the child. The children in these instances were gifted examples. The more ordinary child fell to howling as the easiest way of provoking emotional response, giving vent to what Locke called the "stomachful cry." Locke said that children, earlier perhaps than their elders thought, were very sensible to praise and commendation. They found a pleasure in being esteemed and valued, especially by their parents; but when the child, through some excess of egotism, issued a challenge, when it did some persistent act intending to disturb and dominate, then and then only must punishment be inflicted. Locke practised restraint in the matter of punishment. "It is mere cruelty and not correction," he wrote, "to put their bodies in pain without doing their minds any good." He counselled that they be chastised, "without passion, sparely, and yet effectually." They would seldom, he added, need like punishment again. Locke had also something to say about the difficult school-boy; who, in the oft-repeated words of the school report, "could do better," lacked concentration, would not attend. He pointed out that some boys were idle through sheer love of idleness, but with many others the more they were appealed to or threatened the more lamentable was their performance. Dr. Cameron illustrated his point by relating how a surgeon brought his boy to him one day with a sheaf of school reports couched in terms which would have squeezed the self-confidence out of a judge on the bench. He said to the father, "Suppose for a moment that it was possible to value your surgical work in terms of numbers, and that every week at your hospital the marks you had received, with those of the other surgeons, were posted up, and you were invariably at the bottom, and the governors of the hospital called you in and suggested that you return on Saturday afternoon and perform twenty hernias, with what success would your work be carried on?" Locke was wiser than some modern teachers. He wrote that it was "the usual method of tutors to endeavour to procure attention in their scholars and to fix their mind to the business in hand by rebukes and corrections if they found them ever so little

wandering. But such treatment, Locko said, might produce a quite contrary effect. Passionate words or blows filled the child's mind with terror and affrightment, leaving no room for other impressions. It was as impossible, declared the author of the *Essay on Human Understanding*, to draw fair and regular characters on a trembling mind as on a trembling paper.

#### SPIRITUAL HEALING: AN ECCLESIASTICAL VIEW.

THE Bishop of Durham, Dr. Hensley Henson, in his address to the Durham Diocesan Conference on Saturday, March 14th, spoke at some length about spiritual healing. He asserted that spiritual healing meant no more and no less than mental healing, that the faith which effected the marvellous healings of ecclesiastical record, and created a number of miracles about saints and shrines, need not be distinguished from suggestibility. Faith healing was common to all religions, and there was nothing distinctively Christian about the "Christian healing" described by Mr. J. M. Hickson. In the bishop's opinion, Mr. Hickson's conception of faith hardly rose to the Christian level; his notion of prayer seemed frankly pagan, and his reading of Christian history quite mistaken. On Mr. Hickson's view it would appear, said the bishop, that his healing power was coextensive with that of Jesus as described by the evangelists; but it did not appear that Mr. Hickson had claimed to have actually raised the dead, although his ability to do so was clearly implicit in his general position. Dr. Hensley Henson observed that the science of psychology was throwing a flood of light on that obscure region in which the psychical operated upon the physical. The healing of disease was the incommunicable task of the physician; and the Christian ministry was not charged, and could not seriously concern itself, with this healing. When Mr. Hickson called upon the Church to revive this part of her ministry—physical healing—which he alleged had been lying in abeyance so long, the bishops owed it to the Church to declare their deliberate judgement. Mr. Hickson, in his enthusiasm for "spiritual healing," was led to use language which implied that the cessation of a healing ministry in the Church had been calamitous to mankind. When miracles of healing were most numerous, the bishop observed, public health was least satisfactory. The wonderful advance in medical science had been conditioned throughout by its hard-won independence of theological presuppositions and ecclesiastical control. "It cannot be the duty of the Church," concluded the bishop, "deliberately to return to the beliefs and methods of a primitive and superstitious past." Bishop Hensley Henson, when Dean of Durham, sat on the committee on spiritual healing which met at Westminster under the chairmanship of Bishop Ryle, Dean of Westminster, and presented a unanimous report to the Archbishop of Canterbury in 1914. He had the opportunity, therefore, of hearing and examining the witnesses who gave evidence before that committee. Mr. Hickson was unable to appear before the committee; in fact, it does not appear that any official investigation of Mr. Hickson's cases has taken place since the British Medical Association appointed a committee to investigate in 1909. (The committee's report appeared in the SUPPLEMENT of July 15th, 1911.) According to the Bishop of Durham, Mr. Hickson admits that the testimonies to his cures fall short of what might fairly be required, so that in the absence of scientific diagnosis before the Bradford mission and examination afterwards they could not be decisive. But Dr. Hensley Henson's opportunities for hearing the claims of healers and for judging the standard of validity in evidence required by medical men have been larger than those of many of his fellow bishops. As a result of these opportunities the bishop, while professing no concern with the faith healer's

gift, which, he says, Mr. Hickson appears to possess, expresses the view that Mr. Hickson would be wise to exercise the gift with caution lest he should do irreparable injury to those who sought his aid. In the bishop's opinion the sphere of conscience is pre-eminently the sphere within which the clergyman's duty is unquestionable. The modern physician can discern the nature of the psychic trouble which arrests and defeats physical treatment, and his knowledge might lead him to desire the clergyman's distinctive service. The bishop's remarks strike us as sound sense, and (if we may venture to say so) as sound doctrine, too.

#### HARNETT V. BOND AND ADAM.

THE sense of uneasiness felt by the medical profession at the result of the trial by Mr. Justice Lush and a special jury of the case of Harnett v. Bond and Adam has, we may hope, been lessened materially by the decision of the House of Lords, given on March 16th, that the judgement of the Court of Appeal (reversing that given in the court below) should be upheld. The case in its three stages has been reported at length in the BRITISH MEDICAL JOURNAL. The proceedings in the King's Bench Division were reported on March 8th, 1924 (p. 449 et seq.), in the Court of Appeal on April 12th, 1924 (p. 692 et seq.), and in the House of Lords on March 14th, 1925 (p. 533 et seq.), and in our present issue at page 579. We have devoted so much space to reporting the case because of the grave effect Mr. Justice Lush's judgement would have had upon the whole medical profession, and the general practitioner particularly, if it truly expressed the law on two most vital questions—first, the standard of reasonable care a doctor must exercise when acting in pursuance of the Lunacy Act, 1890, in order to bring him within the protection afforded by Section 330; and secondly, whether, if such protection be not afforded, a doctor may be made liable in damages for the whole of the period of detention of a patient whom he has certified, even though such patient has been recertified again and again by different doctors during that period. At the conclusion of the hearing of the appeal in the House of Lords on Monday the Lord Chancellor intimated that their lordships had unanimously arrived at the opinion that the judgement of the Court of Appeal was right. The medical profession, thus reassured, awaits the delivery of the reasoned judgement of their lordships with confidence that the law as it affects medical practitioners and mental patients will be clearly and succinctly stated. There is now but one question outstanding: Dr. Bond's act in detaining Mr. Harnett in the Commissioners' office in London for three hours or so was technically unlawful, in view of the fact that the jury expressly found Mr. Harnett to be sane on that date; the Court of Appeal ordered a new trial, to be confined to ascertaining the damages sustained by Mr. Harnett for those few hours' detention, and, we assume, unless the measure of damages is settled out of court, this point will come to trial in due course.

#### MEDICAL SOCIETY OF LONDON.

THE 152nd anniversary dinner of the Medical Society of London was held on Wednesday, March 11th, at the Grand Hotel, with the President, Dr. Eustace M. Callender, C.B.E., in the chair. There was a large gathering of Fellows and guests, and the evening was in every way a success. The toast of prosperity to the Medical Society of London was entrusted to Sir StClair Thomson, President of the Royal Society of Medicine, who in the course of a witty speech reminded his hearers that he was very much one of themselves, being a Fellow of thirty-one years' standing and a former president of their body. Since the Medical Society of London stood for the unity of medicine, it was with special pleasure that he coupled with this toast the name of Dr. Callender, and congratulated the society

on appointing for the first time a general practitioner as its president. In the course of his reply the President mentioned that the lease of 11, Chandos Street, where the Society has had its home for the past forty-five years, is now running out, and he gave some striking illustrations to enforce Sir StClair Thomson's point that the extreme specialization of to-day is injurious. In proposing the toast of the Royal Navy, the Army, and the Royal Air Force, Sir Humphry Rolleston, Bt., President of the Royal College of Physicians, spoke of the gratification felt by the profession that Sir William Leishman, a man who had devoted his whole life to science, should now be Director-General of the Army Medical Service. In his reply Surgeon Vice-Admiral Joseph Chambers, Director-General of the Medical Department of the Admiralty, whose exploits as an old international footballer had been mentioned by Sir Humphry Rolleston, said that the Navy looked on Sir Humphry as its greatest friend. Among other representatives of the services present were Air Commodore David Munro, Medical Administrator of the Royal Air Force, and Surgeon Rear-Admiral Sir Percy Bassett-Smith, R.N. (ret.). The health of the visitors was proposed in a most entertaining speech by Dr. Herbert R. Spencer, who welcomed among the guests the presidents of six daughter societies and the Master of the Apothecaries' Society. After some good-humoured banter directed at Lord Riddell, Dr. Spencer turned to Mr. Basil Hall, and, having complimented him on being President of the British Medical Association—a body to which, he said, every doctor ought to belong—invited him to interest the Association in the rebuilding of the fallen tower of Hempstead Church in Essex, where William Harvey's tomb reposes. Both Lord Riddell and Mr. Basil Hall responded in light strain, the latter acknowledging himself "a schoolfellow of Harvey," though perhaps of a rather later generation than Dr. Spencer might seem to imply. The last toast was that of the President, proposed by Sir Charters Symonds.

#### SUN YAT-SEN.

THE death of Sun Yat-Sen closes the story of another of those members of the medical profession who have preferred to undertake the healing of nations rather than of individuals. His life illustrated the fact, which has been so evident during the last ten years, that the gravest difficulties of the reformer are often encountered only when the first successes have been gained. The thorny problems of adjustment which spring up after a successful revolution have frequently resulted in clouding the reputation of the victor, as was the case with Sun Yat-Sen; it is never easy, therefore, for contemporary opinion to be quite just—the temptation to partiality or to hostile prejudice is too strong. Even if Sun Yat-Sen allowed dreams to become his master, as his opponents have asserted, it must be admitted that some of his visions have been realized. Since the middle of the seventeenth century the Manchu dominion of China had kept back the country from participating in the growth of civilization elsewhere in the world, and until the revolution—in the preparation of which Sun Yat-Sen played so prominent a part—this alien tyranny pressed hardly upon the vast Chinese population. Western influences, including the introduction of European medical teaching, slowly instilled an instinct of revolt against the dominant sterile obscurantism, and the connexion of Sun Yat-Sen with the medical school of Hong-Kong, of which Sir James Cantlie was dean from 1889 to 1896, was probably an important factor in the subsequent liberation of China. Sun Yat-Sen's father, a convert to Christianity, was employed as a missionary agent by the London Missionary Society; Sun Yat-Sen, who was born in 1867, became attached to the hospital of the Anglo-American Mission at Canton at the age of 18, where he developed an interest in

medicine and surgery. In 1887 the College of Medicine was founded by Sir Patrick Manson and Sir James Cantlie in connexion with the Alice Memorial Hospital in Hong-Kong; it has been part of a university since 1912, and a combined conference of the Hong-Kong and China Branch of the British Medical Association and the China Medical Missionary Association was held there last January. To this college Sun Yat-Sen came when it opened, and obtained its licence to practise medicine and surgery five years later. He then began medical practice in the Portuguese colony of Macao, where was a hospital half of which was devoted to Chinese and the other half to Western methods of treatment. Sun Yat-Sen worked in this latter half, taking special interest in surgery. Whilst in Macao he had joined the Young China revolutionary party, and, on removing to Canton, he formed a branch there, beginning the fifteen years' work that was to triumph eventually in the expulsion of the Manchu dynasty. After an unsuccessful attempt to capture the Canton arsenal, Sun Yat-Sen fled to Honolulu, and thence by way of America to London. In October, 1896, he was arrested by the Chinese in London, and imprisoned in the Chinese Legation for ten days. It was a curious episode to happen in an ordinary-looking house in the West End of London, but the prisoner might easily have been deported clandestinely had not Sir James Cantlie, almost by accident, got into communication with him. The intervention of Lord Salisbury, then Prime Minister and Foreign Secretary, brought about his liberation. The life of Sun Yat-Sen was at this time largely a blend of organization work and narrow escapes, as much as £100,000 being offered at one time for his capture. He continued actively the work of preparing for the revolution which broke out in November, 1911, and he accepted the provisional presidency of the republic which followed. He retired in favour of Yuan Shi-Kai, but continued to co-operate with him for six years, after which differences of opinion led to Sun Yat-Sen's endeavour to set up a separate Government in Canton. He was later elected President of a Southern Chinese Republic, but in 1922 was expelled from Canton by a revolt. His power was re-established in the following year, and at the end of 1924 there seemed to be a possibility of fresh developments in the North of China. Sun Yat-Sen proceeded to Peking, but was shortly after incapacitated by the illness from which he has now died. When the mists and misunderstandings that still confound the progress of China have finally lifted, it is probable that Sun Yat-Sen, in spite of his mistakes, will be recognized as one to whom his country owes deep gratitude for his active share in her liberation.

#### CONTAGIOUS BOVINE ABORTION AND UNDULANT FEVER.

IN a note published on July 5th, 1924, we drew attention to the close relation existing between the organisms of contagious bovine abortion and human undulant fever. At a joint meeting of three of the sections of the Royal Society of Medicine held last week, this formed the subject of a joint discussion, reported at page 554. Two points of general interest are suggested by this discussion. It indicates that contagious abortion in Southern Rhodesia is apparently transmissible to the human species; and that the undulant fever so caused differs definitely, but only slightly, from typical Mediterranean fever. So far the two diseases, although undoubtedly very similar and closely related, cannot be regarded as identical. From Mr. Bevan's remarks it seems that although contagious abortion has been present in Rhodesia for many years, it is only recently that mankind has become infected. Apparently either the bovine strain has become more virulent, the human race has become more susceptible, or some third factor, at present unknown, has entered into the problem. Now a very large number of cattle in this country eliminate

the bacillus in their milk; and, as Sir Percy Bassett-Smith pointed out, the British cannot be considered immune to the disease. The organism in this country seems to differ from the Rhodesian organism only in its pathogenicity to man. It is therefore all the more important to elucidate these unknown factors in Rhodesia, and to ascertain whether or not a low-grade undulant fever exists in this country. The fact that it has not so far been identified does not altogether preclude the possibility of its being present. The circumstances illustrate once more the great importance of continued and increased co-operation between human and comparative medicine. Although the need for these two allied subjects to come together has only of late been generally appreciated, many far-seeing men have recognized the mutual benefits which could be obtained by such an understanding. Chief among these in recent times was the late Sir Clifford Allbutt, the first president of the recently created Comparative Medicine Section of the Royal Society of Medicine. Another of the great pioneers on this work was the immortal John Hunter; it was he who was mainly responsible for the foundation of the London Veterinary College over a century ago, and, with it, the veterinary profession. There is little doubt that, but for his untimely death a few years later, the connexion between human and veterinary medicine would have been much more intimate than it now is. In this, as in so many other respects, Hunter's ideas were far in advance of his time, and it is only in recent years that steps have been taken to promote this closer association. The discussion on Malta fever shows that this connexion must not be confined to temperate climates, but that it is at least equally essential in the tropics.

#### VERONAL.

The dangers attending the unrestricted sale of veronal are shown in a striking manner in a recent article in the *Journal of the American Medical Association*, where Drs. Leake and Ware<sup>1</sup> give an account of no fewer than sixty-one cases of veronal poisoning treated within the last two years in a single institution, the Los Angeles General Hospital. This very high figure can be accounted for by two facts—first, the unrestricted sale of veronal in California, and secondly, the presence in Los Angeles of a large class of persons of unstable character, and nearly all the persons treated were thus handicapped, and belonged to an inferior section of society. Eighteen were veronal addicts, ten were chronic alcoholics, eight were morphinists, and one a cocaineist. In nineteen cases the drug was taken with suicidal intent. The patients were for the most part inordinately liars, and often denied having taken the drug. The symptoms of veronal poisoning are not very characteristic. The authors remark that often, in the absence of a true history, the nature of the poisoning could only be determined by analysis of the urine or the stomach contents. Hence they suggest that many cases of death from veronal poisoning may escape recognition. The evil, therefore, may be even greater than suggested by the figures given above. As has been said, there is no restriction on the sale of veronal in California, and it can be bought by anyone without a doctor's prescription; this state of things is held to be responsible for its popularity as a drug of addiction and a means of suicide. This failure to control the sale of veronal is not universal in the United States, for New York has followed the present English practice of forbidding the sale of veronal except on a doctor's prescription.<sup>2</sup> The figures given by Leake and Ware reveal clearly the evils which may arise from unrestricted sale. Veronal poisoning on the scale described above has never been known in this country, but even with our present regula-

tions it is unnecessarily frequent, and hence additional regulations will be welcome. The editor of the *Journal of the American Medical Association* points out,<sup>2</sup> however, that America is considerably in advance of this country as regards another aspect of the problem. He discusses a recent article in the *BRITISH MEDICAL JOURNAL*,<sup>3</sup> in which we deplored the host of unnecessary barbituric derivatives exploited under every kind of fancy name, and stated to be endowed with every virtue that any hypnotic can possess and devoid of every fault. In England there is no guide at the disposal of the medical practitioner to enable him to distinguish between a valuable new discovery and an old drug under a new name. In America the American Medical Association has furnished such a guide through its Council of Pharmacy and Chemistry, which publishes annually a volume entitled *New and Non-official Remedies*, and only admits to this list substances the utility of which has been established. Hence the practitioner who confines himself to this list can be certain that the claims of any new drug that he wishes to try have passed the scrutiny of an impartial tribunal.

#### CARE OF CRIPPLED CHILDREN.

THE Board of Education, in a recent circular, drew attention to the need of better provision for the education of physically defective children, and suggested that each local authority should now consider the preparation of a good orthopaedic scheme. It is pointed out that if such a scheme is established as part of the school medical service on the lines sketched by the Board's chief medical officer, one of the main sources of the supply of physically defective children will be closed, and the need of special schools for cripples would be correspondingly reduced. In 1919 the Central Committee for the Care of Cripples drew up the comprehensive scheme for the education, treatment, and after-care of crippled children which was adopted by the Board of Education. Although complete schemes exist in some counties, including Shropshire, Buckinghamshire, Berkshire, and Oxfordshire, the provision in most counties is either inadequate or non-existent. At a conference organized by the Central Committee which opened on March 12th the Duchess of Atholl pointed out that whereas about 106,000 children in England and Wales had been certified as physically defective, there was available accommodation for only 16,000. More hospital centres were wanted, as well as clinics for continued treatment and the adjustment of surgical appliances. In many cases it was possible to effect cure as the result of definite treatment. In the final session of this conference on March 14th, Dr. Eichholz advocated the combination of all the agencies concerned with the physically defective child in one central association, which should be in touch with all education facilities, so that restoration to physical efficiency, vocational training, and the full development of citizenship could be synchronized without interruption. Such an association would have as its objective the preparation of crippled children for active life.

#### INFLUENZA.

LAST week the deaths from influenza in the great towns increased slightly, from 346 to 361, and the notifications of pneumonia in England and Wales from 1,306 to 1,441. In London the mortality from influenza continues to decline; it fell from 64 to 59, and the increased mortality in the great towns as a whole is attributable to certain of them—namely, Liverpool, where the deaths increased from 7 to 26, Nottingham, an increase from 4 to 14, and Birmingham, an increase from 15 to 26. Three other large towns returned 10 or more deaths—Stoke-on-Trent (12), Croydon (10), Portsmouth (10). The increased prevalence of pneumonia is very distinct in the Midlands.

## ROYAL COMMISSION ON LUNACY AND MENTAL DISORDER.

### BRITISH MEDICAL ASSOCIATION EVIDENCE (*continued*).

The session of the Royal Commission on Lunacy and Mental Disorder was occupied on March 11th with further oral evidence tendered on behalf of the British Medical Association. The Memorandum of Evidence appeared in the SUPPLEMENT of January 17th (p. 29), and the report of the first hearing in the JOURNAL of January 24th (p. 170). The witnesses attending on the second occasion were Dr. R. Langdon-Down (chairman of the Association's Committee on Lunacy and Mental Disorder), Dr. J. W. Bone, Dr. C. O. Hawthorne, Mr. E. W. G. Masterman, Dr. Christine Murrell, and Sir Jenner Verrall, with Dr. C. Courtenay Lord (Assistant Medical Secretary).

### Licensed Houses.

The Chairman of the Commission (the Right Hon. H. P. MACMILLAN, K.C.) said that there were some supplementary topics on which the Commission thought it desirable to have the opinion of the Association. The first of these was with regard to the position of the licensed house. This was dealt with in paragraph 54 of the Memorandum of Evidence, which stated that the Association was satisfied that there existed a desire in the community generally that many patients should be able to be treated otherwise than in public institutions. He imagined that the objection in principle which was taken in some quarters to this type of institution was that it might give rise to a possible conflict between duty and interest on the part of the management.

Dr. Langdon-Down said that he believed that was the basis of the theoretical objection sometimes urged, although as a matter of fact the reports with regard to these houses were by no means adverse to them in the main. It was really for the benefit of the patients and their friends that the Association urged the position which was set out in paragraph 54. He thought that those who put forward the view that there might be a conflict between duty and interest overlooked certain considerations which told the other way—for example, the desire to do a good thing and to do it well, and the importance of gaining and maintaining a good reputation.

The Chairman said that there did seem to be some anxiety in the public mind with regard to the profits made by the proprietors of such establishments. There was a suspicion of large profits undisclosed.

Dr. Langdon-Down replied that he was afraid he was not in a position to say anything with regard to the profits, but he did not think any suggestion of exploitation could be justified. He regretted the unavoidable absence of Dr. F. H. Edwards, who had furnished to the committee some figures showing the recovery rates in these houses, and, although he himself could not recall them, he believed they compared favourably with those relating to public institutions.

The Chairman said that Dr. Edwards might be called later. He went on to point out that in the case of patients who were rate-aided there was comparatively little motive for unnecessary detention; the only ground on which such detention had ever been suggested as possible was that a patient might have made himself extremely useful to the institution. In the licensed house, on the other hand, there was possibly more public anxiety, because the inmates were generally persons of some means, and there might be a motive on the part of the relatives to keep them there unjustifiably, and also a pecuniary interest in their detention on the part of those conducting the establishment. Positive ill treatment in such institutions was perhaps less likely than in public institutions, because the patients had means and could command better attendance, but the possibility of wrongful detention seemed to be rather greater, and behind the whole thing was a question of public policy, that money should not be made out of such circumstances.

Dr. Langdon-Down said that the present position whereby a veto existed against the setting up of new houses was illogical. If a thing was wrong it should not exist at all, even in a limited form; if it was right to have such institutions, the supply should meet the demand.

The Chairman, in reply to a remark by Sir Jenner Verrall, who instanced the parallel of the nursing home, said that the Commission was not entirely without evidence that abuses had occurred in licensed houses; that, of course, was a reason for stiffening the safeguards. The question was whether the public at large desired this kind of institution. The nursing home, of course, of which the licensed house was the counterpart in mental cases, had come to stay; but then, in the ordinary nursing home, the patient remained more or less a free agent—at all events there was no legal ingredient. He took it that it was the view of the Association that if the safeguards were

adequate this type of institution should be encouraged rather than discouraged.

Dr. Langdon-Down said that that was so. He also pointed out that the attitude of the Legislature, which in 1890 was rather against licensed houses, was modified in 1913 when the Mental Deficiency Act was passed, for in that Act the wisdom of allowing institutions run for profit or from motives of semi-charity to deal with mental deficiency cases was recognized. In answer to Sir Humphry Rolleston, he added that he would not like it to go forth that the Association was desirous in any way of fortifying a monopoly.

The Chairman remarked that it was rather odd that in 1913 it should have been recognized that premises might be approved for the reception of defectives, although the institutions were run for private profit. He asked whether the witness believed that the demand for licensed houses justified their retention and encouragement, notwithstanding the risks attaching to them.

Dr. Langdon-Down replied that he thought the public might be divided into two categories: those who had relatives who wanted this care and treatment, and those who had not. The latter took a detached and *a priori* view, but the former—those who were interested in particular cases—asked for and wanted these institutions.

The Chairman thought that complaints had been made more frequently against licensed houses than against public institutions. Dr. Langdon-Down pointed out that this might be because the medical superintendent or proprietor of a licensed house was more readily "shot at." The person who had a real or fancied grievance believed himself likely to get more out of him than out of the medical superintendent of a public institution.

The Chairman said that the proposals of the Association under this heading must be linked up with its general proposal for a provisional order. A provisional order might eliminate a number of cases which would otherwise reach licensed houses, and in that way diminish their transitory population.

### Functions of the Medical Superintendent.

The Chairman stated that a considerable body of evidence had come before the Commission to the effect that the medical superintendent's work as a doctor was interfered with by his administrative duties. He asked for the views of the Association.

Dr. Langdon-Down said that he did not think his committee had discussed that point. His own view was that the whole of the circumstances in which a patient was situated affected his treatment, and that there would be great difficulties in dividing up the management of an institution. The supreme authority ought to be the medical superintendent, who should be able to impose his will on every department.

The Chairman instanced the analogous case of the nursing home, where the doctor in charge did not concern himself with administration, but entrusted the matron with general oversight. The physician or surgeon at the head of a nursing home was not "cumbered with much serving," as was the head of a mental institution.

Dr. Langdon-Down pointed out the difference between a resident medical superintendent and a doctor in charge of a nursing home who lived outside. The medical superintendent, of course, if the institution was big enough, should have several departmental chiefs under him.

The Chairman said that the Commission had been informed in evidence of a medical superintendent who took such an interest in a farm attached to his institution that he developed into an admirable farmer, but to the disadvantage of his medicine. It could not be regarded as ideal if a medical superintendent had his attention diverted so largely to administrative matters that he was compelled to delegate his medical duties to subordinates. It was a matter, of course, largely of temperament; some superintendents might prefer the administrative to the medical work. But he thought the Association would agree that as far as possible the medical superintendent should be able to free himself from the routine matters of administration, and, among other things, should have opportunity to acquaint himself with the advances of medical science, particularly in regard to mental disease.

Mr. Masterman said that he was medical superintendent of a Poor Law hospital with 800 beds. All the financial side was entirely out of his hands, but he agreed that it would be impossible for a medical superintendent to divorce himself wholly from responsibility for the administrative as well as for the professional side. He himself would, of course, be consulted on anything affecting structure or general arrangement in his own institution, but he would not concern himself with details.

### After-care.

The Chairman next sought the opinion of the witnesses on after-care, which was discussed in paragraph 43 of the Memorandum. Two views had been laid before the Commission—one

that it was desirable to have associations, preferably of a voluntary character, to assist the patients in getting back to ordinary life; the other, that many patients, having left the institution, would desire to close the episode, and would resent people, however well intentioned, busying themselves with their affairs.

Dr. Langdon-Down thought that it would be well if those concerned in the working of the asylum took a larger share in the after-care arrangements, particularly by habitual communication with the patients' doctors after the patients had left the asylum.

Dr. Christine Murrell said that the committee had felt that patients suffered from lack of continuity. When a patient went into an institution, his doctor as a rule—not always—was asked to send a report to the medical superintendent, but it was not the custom when the patient was discharged for the medical superintendent to communicate with the patient's own practitioner.

The Chairman said that it had been impressed upon him that the transition from institutional to ordinary life must be a very critical period in the history of the individual. Dr. Langdon-Down agreed, and added that it was important that the period of actual insanity should not be regarded as a separate episode, but should be a part of the entire medical history.

Mr. Micklem asked whether, when a patient on some insurance practitioner's list went into an institution, he did not automatically drop out of insurance, and therefore had no doctor to whom to return. Dr. Bone said that such a patient did not come off the list for a considerable period—more than a year. He believed the longest period possible was one year and nine months. But when he resumed work he would immediately enter again into insurance, though whether he went on the list of the same insurance practitioner or not would be a matter for his choice.

Sir H. Rolleston asked whether the Association would support any scheme for social service connected with mental hospitals whereby cases might be visited afterwards by a friendly body of visitors, who would be to all intents and purposes members of the staff of the institution. Dr. Langdon-Down could see no objection, but the Association had not considered the matter. It would be a logical extension of after-care. Dr. Murrell begged that if the Commission made any recommendation to that effect the consent of the patient would be obtained. The patient might not want the asylum to follow him home. Given such a safeguard, the medical value of any scheme of the kind would be enormous. The Chairman agreed that the wishes of the patient should be safeguarded.

#### *Treatment of Mental Cases at General Hospitals.*

The Chairman said that on the previous day, in evidence from the Mental Hospitals Association, the question of the assimilation of the treatment of mental disease in its early stages to the treatment of tuberculosis or venereal disease at public clinics had been discussed. At present these other diseases were dealt with in special premises, and, in the case of tuberculosis, in-patients as well as out-patients were provided for. Would it be possible for similar clinics to be established for mental disease short of insanity? The theory was simple, but the practice might be difficult.

Dr. Langdon-Down said that he thought that some such provision for mental cases might be linked up very advantageously with the teaching hospitals. Opportunities would thereby be afforded for the study of mental disorder by those entering the practice of medicine; such a plan, moreover, would help to prevent the unjustifiable severance of psychiatry from medicine in general.

The Chairman said that the whole conception was most attractive, but any such arrangement must take one of three forms: (1) a department of an existing asylum; (2) a branch of a general hospital; or (3) a separate institution similar to the clinics already set up for dealing with tuberculosis and venereal diseases. He gathered that the second of these proposals was the one favoured by the witnesses, but it was one which might encounter opposition from those conducting general hospitals; the introduction of these cases might be resented. Dr. Langdon-Down said that he thought the tendency now was to encourage psychiatric departments in general hospitals.

Mr. Micklem asked whether it was contemplated that cases should go to these clinics under temporary orders. The Chairman said that he did not see how such a department could be conducted unless some form of restraint was available, and this would involve registration and the whole apparatus over again, and would be resented by the management of the general hospital.

Dr. Langdon-Down described the psychiatric clinic of Professor Winkler, at Utrecht, to which patients came voluntarily and yet were detainable. In reply to the Chairman, who asked how the carrying on of such an institution was

reconciled with the legal aspect, Dr. Langdon-Down said that he was afraid things were done in Utrecht which might not have the approval of the legal authorities in this country, but he promised to obtain for the Chairman a copy of an address which Professor Winkler delivered not long ago to the Medico-Psychological Association, and which the Chairman said he would read with great interest.

Dr. Langdon-Down added that he wished to make one emendation of his oral evidence given on the former occasion. He had stated that it was unfortunate that there were not institutions for the treatment of mental illness short of insanity. That was a hasty generalization, and, of course, there were a few such institutions, notably the Lady Chichester Hospital at Hove, the Maudsley Hospital, and an institution in Edinburgh.

Mr. Masterman pointed out that Maudsley Hospital was in very close association with King's College Hospital and had the services of its staff when required. That, indeed, was a model of what might be done. Maudsley was not under the control of King's College, but was associated with it. The Chairman said that he feared that when once a hospital was given a special name it became in the popular mind an asylum. Mr. Masterman said that he could testify, as one living in the neighbourhood, that Maudsley in the minds of the people round about had a quite distinct signification, apart altogether from that of an asylum.

#### *Protection for Certifying Doctor.*

Dr. Hawthorne again raised a matter discussed on the previous occasion in connexion with the claim that the certifying practitioner should enjoy the immunities of a witness in a court of law. One of the members of the Commission had suggested that there was a parallel between a lunacy certificate and a certificate given in a case of diphtheria or small-pox, and that as a medical certifier could not avoid a legal responsibility in the case of the latter it was reasonable to infer a similar responsibility in the case of the former. But there were two respects in which these two classes of certificates differed the one from the other. In diphtheria, for example, the doctor offered himself to the community as one who was ready and willing to certify and to do whatever was necessary in the case. It might be said that it was the same in lunacy, but there was a difference. The doctor undertook with great reluctance to certify a patient as a lunatic. The total amount of this work which fell to the individual doctor in the course of his career was very small, and the remuneration negligible. In the case of these lunacy certificates, the witness submitted, the doctor acted as a public servant, whereas in the case of certificates given in diphtheria or small-pox he acted in the proper and ordinary practice of his profession. The second difference was that in a certificate of a certifiable disease the doctor expressed an opinion only, he did not state the facts upon which he founded that opinion; in lunacy certificates the facts had to be stated to the judicial authority, who had the right to accept them or challenge them, to act upon them or to decline to act upon them. Therefore the certificate had a different quality, and the analogy drawn by a member of the Commission at the last hearing was fallacious.

The Chairman said that he gathered that the Association contended that the immunity of the certifying doctor should be as complete as the immunity of a witness testifying in a court of law. But it must be remembered that the doctor was a professional man who held himself out as able to perform certain things in which he was skilled, and he must be judged by that criterion. If, therefore, it could be shown that he had performed his function carelessly or in bad faith he ought not to be protected. If a doctor made a malicious statement on a certificate—a statement perhaps not on a professional but on some collateral matter—was he to be protected?

Dr. Hawthorne said that no one asked for any protection for a doctor making false statements. The Chairman instanced the hypothetical case of a doctor giving a certificate while drunk. If the legislative protection which the Association wanted were accorded, he would be absolutely safe. Dr. Hawthorne thought it difficult to imagine a case of a doctor who, being drunk, was yet able to construct a certificate commending itself to the judicial authority.

Some discussion took place on the question of onus of proof, and the Chairman gave an account of the legal procedure in Scotland, which he considered more favourable than the English system to the doctor against whom a complaint was made with regard to a certificate. He went on to say that it was asking a great deal of the Commission to recommend that the certifying doctor should be placed in the position of a witness giving oral testimony in a court. Even such a witness was not entirely protected. If he committed perjury he was subject to legal process.

Dr. Hawthorne said again that he did not ask that the doctor should be free from responsibility for perjured statements.

The Chairman pointed out that the whole procedure of certification was administrative rather than judicial. He agreed that it was very undesirable that members of the profession should feel that they were performing their work under the possible menace of legal action, to answer which, even though they were found guiltless, might involve them in severe financial loss. But while anxious to give every encouragement to the profession, he felt there must be preserved in the law the right of action where action ought to lie.

Sir Jenner Verrall spoke of the risk of doctors not doing their duty unless some increased protection were accorded.

Dr. Murrell asked whether it would not be possible to increase the responsibility of the judicial authority. If the risk of the medical certifier could not be lessened, could not the judicial authority at least be associated with the risk? The Chairman said that the judicial authority was not exempt from possible action, though he agreed that, generally speaking, it was against the medical certifier that action was taken.

This concluded the evidence of the British Medical Association, and the witnesses were thanked for the assistance they had given to the Commission.

## South Australia.

[FROM OUR OWN CORRESPONDENT.]

*The British Medical Association.*

DR. RIDDELL of Kapunda retired from office as President of the South Australian Branch of the British Medical Association last June, and was succeeded by Dr. Steele Scott of Malvern. The outstanding feature, perhaps, of the year's scientific work was the Listerian Oration delivered by Mr. F. A. Hadley, F.R.C.S., of Perth, Western Australia, on "Deformities of the alimentary tract." A medal has now been struck, which has been presented to all who have delivered this oration in the past. In addition to the medal, the interest from a small endowment fund which has been established will be handed to the orator in futuro to help to defray his travelling expenses.

### Medical Politics.

Our fairly satisfactory Medical Act was recently in danger of being wrecked by an amending bill introduced by an irresponsible member of the lower house. He proposed to allow the registration in South Australia of such men as had been medical officers of an armed transport during the war and had been discharged with a good character after a year's service. There have been instances recently in which persons have been registered in one of the Australian States on the strength of American diplomas, and it has afterwards been ascertained either that they did not hold such diploma or that it was not of a character to warrant registration. All the Labour members who spoke seemed to think that the British Medical Association was at the bottom of some tyrannical objection to registration. The sensible view taken by Mr. Denny, the Attorney-General, in opposing this private member's bill probably influenced the Labour cabinet to vote against it, and its second reading was lost by 18 to 15 votes.

### The Medical School.

Dr. Cleland's chair of pathology is transformed into the "Marks Professorship," and in addition a Keith Sheridan Fellowship has been created with the bequests mentioned in my last letter. Professor Brailsford Robertson will probably direct his energies more particularly to his favourite study of biochemistry, and a Marks lecturer on applied physiology will be associated with the Sheridan Fellowship. Preventive medicine has suffered a great loss by the death of Dr. Thomas Borthwick, the health officer for the city of Adelaide, the first man in South Australia to devote himself exclusively to health work. His successor is Dr. Angus Johnson, a member of the corporation. At the hospital Dr. Darcy Cowan has been promoted to full physicianship, and two vacancies in the out-patient department have been filled by the appointment of Drs. Guy London and Southwood. The lectureships on obstetrics and gynaecology have been reunited, after more than twenty years' divorce, in the person of Dr. T. G. Wilson, Dr. A. A. London, the last of the original staff, having resigned the former of the two posts.

*Royal Society.*

The last three presidents of the local Royal Society have all been medical graduates. When Sir Joseph Vereco declined re-election after holding office for about eighteen years he was succeeded by our local authority on orchids, Dr. R. S. Rogers. Dr. Pilleine, who is an omnivorous scientist, has now completed a year in office, and has given way to the professor of geology, Sir Douglas Mawson, of Antarctic expedition fame.

## England and Wales.

### LIVERPOOL VOLUNTARY HOSPITALS.

At the annual meeting of the Royal Southern Hospital on March 3rd, when the Right Hon. the Lord Mayor presided, it was stated that the effort to establish a co-operative contributory scheme in Liverpool, on lines which have brought relief to hospitals in other large centres, is making satisfactory progress and would receive the speaker's whole-hearted support. The financial position of the hospital is a matter of grave concern to the committee; not only is it living considerably above its income but has an overdraft of £20,000. The cost of maintenance showed an increase during the year of £2,164, due chiefly to the increased cost of provisions, surgical and dispensary items, and salaries and wages. The total number of in-patients in 1924 was 2,673, as compared with 2,472 in 1923; the total number of out-patients was 21,922 with 88,780 attendances, showing an increase of 2,956 and 11,078 respectively over the corresponding figures in 1923. The important event of the year was the opening of the electro-therapeutic and massage department last October to commemorate the jubilee of the hospital (1922). There is now a special clinic for heart diseases equipped with an electro-cardiograph. It was reported that the Newbolt Memorial Fund in memory of the late Mr. G. P. Newbolt, F.R.C.S., amounted to £1,264, and was being utilized to enlarge the x-ray department, in which he took a keen interest during the whole period of his twenty-six years' service. The committee records in its annual report with profound regret the loss of Mr. Newbolt, and adds its sincere testimony and appreciation of his great loyalty and devotion to the hospital.

### The Liverpool Royal Infirmary.

The annual meeting of the Royal Infirmary, Liverpool, took place on March 13th at the infirmary, under the presidency of Dr. T. R. Glynn, consulting physician and emeritus professor of medicine. The x-ray department has been extended and a new ward—the Larrinaga maternity ward—in connexion with the gynaecological department is to be ready in the near future. The number of in-patients in 1924 was 5,069, and exceeded the admissions of the previous year by 289. The number of out-patient attendances amounted to 174,795, and the number of new patients showed an increase of 2,017 over that in 1923. The financial statement showed that the expenditure was £7,714 above the annual income, and that the accumulated deficit on the general maintenance account amounted to £24,210. The new nurses' home is badly in want of funds, and £25,000 is required to complete the second portion of the building. During the past year Dr. R. J. M. Buchanan, honorary physician for twenty-three years, and Mr. W. Thelwall Thomas, honorary surgeon for thirty-three years, have retired and were appointed consulting physician and consulting surgeon respectively by the meeting, which recorded its appreciation of their services and devotion to the hospital.

### MAUDSLEY HOSPITAL LECTURES.

The second part of the eighth course of lectures on psychological medicine at the Maudsley Hospital will commence early in April. Dr. F. C. Shrubbsall will deliver eight lectures on the practical aspect of mental deficiency on Wednesday afternoons, beginning April 1st, and eight lectures on morbid psychology will be given by Dr. E. Mapother on Tuesday afternoons from April 7th. On

Monday afternoons, from May 4th, Dr. Bernard Hart will deal with the psychoneuroses, and on Tuesday afternoons six lectures on the pathology of mental diseases will be given by Sir Frederick Mott, beginning on May 5th. Six demonstrations in clinical psychiatry will be given on Wednesday afternoons, commencing May 6th, by Dr. E. Mapother, and twelve clinical demonstrations in neurology by Sir Frederick Mott and Dr. F. L. Golla on Thursday afternoons from April 2nd. Lectures on crime and insanity by Dr. W. C. Sullivan, and on the legal relationships of insanity and treatment, will be given on dates to be announced later. Further information may be obtained from the Director of the Pathological Laboratory, Maudsley Hospital, Denmark Hill, S.E.5.

#### LONDON CONFERENCE ON VENEREAL DISEASE.

A conference of representatives of London local authorities and propaganda committees associated with the venereal diseases scheme for London was held at the County Hall on March 16th under the auspices of the National Council for Combating Venereal Diseases. Mr. E. B. Turner, F.R.C.S., who presided, pointed out the greatness of the field covered by the London scheme, embracing as it did a population of eight million. During 1924 the number of meetings in furtherance of the anti-venereal propaganda was 258, and the number of people directly reached was nearly 37,000—a small figure in relation to the population of London, but including many people of local influence, such as borough councillors, school teachers, and church workers. Dr. Letitia Fairfield then gave an address on the working of the London scheme. The scheme, she said, involved arrangements with eighteen general and ten special hospitals, and the value of the anti-venereal work done in London was enormously assisted by the interest of the teaching schools, which ensured that the medical practitioners of the future would know a great deal more about venereal disease than the medical profession had known in the past. At St. Thomas's, Guy's, St. Paul's, the Royal Free Hospital for Women, and the Lock Hospitals the clinics were now open for practically the whole day, so that there was no excuse on the part of patients that their professional or industrial occupations deterred them from attending. Seven hostels for women had been established, all of them in connexion with general hospitals. A gratifying feature was the extent to which laboratory facilities were being used by general practitioners as well as public health officers. Dr. Mary Scharlieb spoke on the organization and work of local committees. The happiest method of propaganda, she said, was by a judicious mixture of voluntary and official work. When one found in any borough public health authorities acting on their own, without co-operation with voluntary workers, there was a lack of intimate touch with the problem. Officialdom without its voluntary partner was officialdom partially paralysed. Professor H. R. Kenwood gave an address on the work of the National Council. Drs. Dorothy Hare and Margaret Rorke spoke on the women's hostels, and there was a good deal of general discussion in the way of an interchange of experiences between representatives of different boroughs, chiefly on the question of propaganda.

## Scotland.

#### ODONTO-CHIRURGICAL SOCIETY OF SCOTLAND.

The annual meeting of the Odonto-Chirurgical Society of Scotland was held in the Dental Hospital, Edinburgh, on March 6th, under the presidency of Dr. H. Gordon Campbell. A paper on immediate and remote effects of infections of the mouth was read by Dr. J. E. McCartney, lecturer on bacteriology in the University of Edinburgh. It was possible, he said, in an average month to find anything from 100 to 150 different organisms. Many of these, no doubt, were merely transient residents, having been introduced by food, but others were more permanent. The total number of organisms in the mouth was in the

main determined by the cleanliness of the patient and the variety of food taken; starchy foods were those most likely to encourage the growth of organisms. Rheumatic troubles would be better treated at the seat of origin than by local counter-irritants, and treatment should be carried out before the infection was well advanced, for then the damage had been done. Another point he emphasized was the futility of mouth-washes, which did not produce an effect beyond the surface of the gums, while infection needed more radical treatment.

#### GLASGOW VETERINARY COLLEGE.

The Royal Faculty of Physicians and Surgeons of Glasgow has forwarded to the Secretary for Scotland a resolution regarding the proposal of the Board of Agriculture and the Government to withdraw grants from the Glasgow Veterinary College. The opinion is expressed that the continuation, maintenance, and advancement of the college as a centre of teaching and research are urgently desirable, and it is maintained that Glasgow is the most convenient and suitable centre for students drawn from an area embracing one-half the entire population of Scotland. It is urged further that the success of the Glasgow College, both in the number and quality of its students, fully justifies its continuance, and that its work in relation to the diseases of man and the lower animals is of vital importance to medical science and to public health, with both of which Glasgow has a profound and intimate concern, and for both of which the whole country is calling for encouragement from the Government. On these grounds the Faculty regrets the proposal to concentrate the teaching of veterinary medicine in one centre in Scotland which is involved in the proposed withdrawal of the grant-in-aid to the Glasgow College.

#### GLASGOW ROYAL HOSPITAL FOR SICK CHILDREN.

Sir Hector Cameron presided over the forty-second annual general meeting of the Governors of the Royal Hospital for Sick Children, Glasgow. The report for 1924 showed that over 6,000 children had been treated in the wards, while at the hospital and at the dispensary in West Grinham Street there had been altogether 77,973 attendances of out-patients. The expenditure of the hospital for the year had been £30,177, as compared with £29,902 in 1923. The chairman, in moving the adoption of the report, expressed the thanks of the meeting to those persons who had responded so generously to the directors' appeal for £75,000 required to meet the cost of additions and extensions. In answer to this appeal £71,000 had been contributed within less than twelve months, and a further £1,000 received that morning left only £3,000 to make up the amount which had been originally required. The chairman declared that when the extensions were completed the hospital would rank as one of the finest and best equipped institutions of its kind in the country.

#### THE PERMANENT CARE OF THE FEEBLE-MINDED.

A lecture was delivered at a meeting of the Edinburgh Women Citizens' Association on March 3rd, when Lady Leslie Mackenzie was in the chair, by Dr. J. Keay, medical superintendent of Bangour Asylum, who estimated that there were in Scotland at the present time 19,686 mentally defective persons; many of them were constantly drifting in and out of poor-houses, reformatories, asylums, and similar institutions. Many others were at large, and the great majority were in urgent need of protection, of training in industrial employment, and of control to prevent the propagation of mentally defective children. Feeble-minded women were nearly twice as prolific as normal females, and, while the birth rate of the normal population had steadily declined since 1878, that of the feeble-minded had increased. The only practical method of dealing with this problem was to segregate them permanently in industrial colonies. Here they would be happy, instead of, as at present, being trained to the age of 16 years and then turned adrift to sink or swim, just at the period of life when training was most essential. No civilized country could afford to neglect this matter.

## Ireland.

**FREE STATE ELECTIONS.**  
By-elections in nine Free State constituencies were held last week. Among the successful candidates was Dr. Thomas Hennessy, Irish Medical Secretary of the British Medical Association. There appear to have been three parties at these elections—Government, Republican, and Labour. Dr. Thomas Hennessy was returned for Dublin (South City) as a Government candidate by 24,075 votes, against 13,900 for the Republican candidate, and 4,237 for the Labour candidate.

**LOCAL GOVERNMENT AND PUBLIC HEALTH BILL (IRISH FREE STATE).**

During the passage of the Local Government Bill through the Senate an amendment making it mandatory on coroners to hold an inquest on a body where there was reasonable ground to believe that death might have been due to causes other than common illness was carried. An amendment was moved to the effect that the county medical officer of health should act as local government inspector in connexion with the administration of county hospitals, county homes, mental hospitals, and dispensaries in the areas assigned to him. At present these institutions are inspected by a staff of some seventeen lay inspectors and ten medical inspectors. Under the bill there would be a new office, county officer of health, and the amendment proposed that he should act as local government inspector. It was urged by senators that economy to the danger of public health was not wise, and the Minister of Local Government and Public Health stated that he could not accept the amendment. He mentioned that his department, which had been taken over from the British, with all its functions, now showed a saving of £15,000 a year. He considered it would be wrong to push untried men in to the position of local officers over the various public health areas. The amendment was withdrawn. A new Government section was proposed, providing that at least one of the sanitary officers appointed by any sanitary authority under the provisions of the Public Health Act, 1878, should be a duly qualified veterinary surgeon, and that his duties should include inspection and examination of meat, inspection of cattle and dairies, and other similar duties. Sir John Keane said that since the question was raised, members of the veterinary profession had been very busy, and seemed to be rather apprehensive that the House was inclined to encroach on their professional duties. What the House objected to was these gentlemen overlapping under different Acts. The Minister of Local Government and Public Health said it was the intention at first to have one veterinary officer to carry out all the co-ordinated duties in the county. Though one veterinary officer would not be able to take on all the duty of the public health district, it would be better to have one than none at all. The section was carried.

**VITAL STATISTICS OF NORTHERN IRELAND.**

During the quarter ending December 31st, 1924, 6,474 births were registered in the twenty-seven superintendent registrars' districts in Northern Ireland, the number being equivalent to an annual birth rate of 20.2 per 1,000 of the estimated population, as compared with the corresponding figures of 17.5 for England and Wales and 20.7 for Scotland. The deaths registered during the quarter numbered 4,592, representing an annual rate of 14.3 per 1,000, as compared with 11.1 per 1,000 for England and Wales and 13.7 per 1,000 for Scotland. The birth rate was 1.7 below the rate for the corresponding quarter of 1923, and 1 below the average rate of the fourth quarters of the ten years 1914 to 1923. The death rate was 0.3 below the rate of the corresponding quarter of 1923, and 2.1 below the average rate for the fourth quarters of the ten years 1914 to 1923. Of the total number of deaths registered, 17 per cent. occurred in public institutions; another 11.8 per cent. were uncertified, there having been neither a medical attendant during the last illness nor an inquest held by a coroner. The equivalent birth rate for the

quarter under review of the county boroughs and urban districts, which contained nearly half the total population of Northern Ireland, was 25.8 per 1,000 of the population, the birth rate for the remainder of Northern Ireland being 16.2 per 1,000. The annual rate represented by the number of deaths from all causes in the county boroughs and urban districts during the quarter was 16.4 per 1,000 of the population, and the corresponding rate for the remainder of Northern Ireland was 13.1 per 1,000. The urban mortality from the principal epidemic diseases was equivalent to an annual rate of 1.2 per 1,000 of the population, the corresponding death rate for the remainder of Northern Ireland being 0.4 per 1,000.

**VACCINATION DEFAULTERS IN DUBLIN.**

Mr. Collins, district justice, recently imposed nominal fines of 6d., with £1 1s. costs in each case, on a number of persons who were prosecuted by the Dublin Union Commissioners for failing to have their children vaccinated. Mr. J. Crowley, for the Commissioners, said there were about 7,000 defaulters in the city, and the Commissioners were determined to have the law enforced. One of the defendants said, in his defence, that he looked upon vaccination as an act of cruelty, and he would be going against his conscience to have his child vaccinated. He felt it was a criminal law.

**Medical Notes in Parliament.**  
[FROM OUR PARLIAMENTARY CORRESPONDENT.]

THE House of Commons has this week discussed the Army and Navy Estimates. In the former debate references were made to the diminished inflow of medical men to the R.A.M.C. The Medical Committee of the House will meet next Monday, and will discuss certain proposed bills of medical interest, including probably a Births and Deaths Registration Bill. The Nursing Homes Registration Bill introduced by Mr. G. Hurst has been printed. The text does not incorporate all the results of recent negotiations between the promoters of the bill and the Ministry of Health, but this, it is stated, is due merely to exigencies of time.

The Performing Animals Bill and the Birds Protection Bill both passed through Grand Committee on March 17th without amendment, and the Government is likely to help their progress towards the Statute Book. On the same day the House of Lords gave a second reading to Lord Carson's bill for the regulation of moneylenders, and agreed that it, together with a bill for a similar purpose which has received a second reading in the Commons, should be sent to a joint committee of both Houses.

**BILLS.**

**Therapeutic Substances Bill.**  
The House of Lords, on March 17th, passed the Therapeutic Substances Bill through Committee and Report without amendment. During the Committee stage Earl Russell said that Clause 2, dealing with the restrictions on the manufacture of therapeutic substances, made no provision for the cost of examination, and asked whether these substances were to be tested by a voluntary committee or by whole-time public officers, and whether the manufacturers of the products were to pay. The Marquess of Salisbury, the Minister in charge of the bill, said the routine tests would be done at the expense of the manufacturers, who would provide samples free of charge. In special tests by the Medical Research Council the expense would be provided out of parliamentary votes. The number of manufacturers was too small to justify the introduction of fees, but if too large a charge were thrown on the Vote for the Medical Research Council in the House of Commons would take note of it, as the tests were in the interest of the public.

On Clause 3, imposing restrictions on the importation of therapeutic substances, Viscount Haldane said that certain substances would be imported in small quantities for purposes of research by men of science, and he asked whether a distinguished physiologist, for example, might be placed on a list and enabled to obtain supplies with a minimum of trouble. Lord Salisbury said it was not proposed that licences should be given for special parcels, but to individuals or to institutions, enabling them to import at will for research. Information that such licences had been issued would be passed to the Customs. All the regulations would be laid before Parliament. Lord Haldane said the explanation was satisfactory.

**Mental Deficiency Bill.**  
Sir Leslie Scott introduced, on March 17th, a Mental Deficiency Amendment Bill, described as a bill to amend Section 7 of the Mental Deficiency Act, 1913, for the purpose of enabling a defective to be removed from an institution for the purpose of being placed under guardianship. He said it was intended to

repair an omission in the Act of 1913, which provided for the transfer of a mentally deficient person from guardianship to an institution, but not for the reverse process. After treatment of a defective in an institution it was sometimes found that such an improvement had taken place that transfer to guardianship was desirable. The bill provided that the transfer could be made under the order of the judicial authority which originally made the order, or under another judicial authority, and by the same procedure as in the original process. As chairman of the Central Association of Mental Welfare, he knew that this small change would be of great advantage. The bill, which was backed by Mr. H. A. L. Fisher, Sir Henry Stessler, Dr. Fremantle, and Mr. G. Hurst, was read a first time without discussion or division.

#### Summer Time Bill.

The second reading of the Summer Time Bill was moved, on March 13th, by Colonel Lambert Ward, and after the Home Secretary had announced that in the event of the bill receiving a second reading it would be taken up by the Government and given facilities for passing through the House, it was read a second time by 289 to 63.

In seconding the motion, Mr. Cooper Rawson said that the bill would be of great benefit to the health of the people, and urged that an argument for the bill was that hospitals would save the money now spent on artificial sunlight, as it would be possible to get the natural sunlight out of doors.

Dr. Little said medicine was on the eve of gaining extensions of knowledge of the properties of sunlight. Members could visit any of the light departments of the great London hospitals and see the transformation of a wreck of humanity into a reasonably healthy person as a result of sitting for half an hour, three times a week, in front of the very feeble imitation of sunshine which came from a carbon arc lamp. The importance of sunlight and fresh air could not be overestimated, and both would be increased to large numbers of people by this bill; he wished the House of Commons itself could receive more sunlight and fresh air than it did. The psychological effect of sunlight was very great. Amazing influence on nutrition was exercised by the application of sunshine and fresh air.

Sir Kingsley Wood, for the Ministry of Health, read a letter from the London County Council, dated March 13th, which contained the following passage: "At one time it was alleged that summer time had a detrimental effect on the health of children and young persons, by leading to reduce the hours of rest, but the Council, in 1921, after consulting the school medical staff and the authorities of elementary, secondary, and continuation schools, and evening institutes, came to the opinion that the consensus of expert educational opinion was that summer time was an advantage to school children and to young persons continuing their education beyond the school age." That was the considered opinion of the greatest educational authority in the world.

Mr. Rhys Davies asserted that medical evidence was definitely in favour of more sun and daylight.

Mr. Lunn, on the other hand, said that if members lived among the people they would see that in consequence of summer time children did not get the sleep they ought to have. Most working-class mothers were opposed to it. Other members supported this view.

The Home Secretary said that the British Medical Association had expressed regret that summer time had been curtailed last year, and declared that it was beneficial to health and efficiency. The council of the Society of Medical Officers of Health recently passed a resolution in favour of summer time for six months each year, and at a deputation in favour of the bill, which he received at the beginning of the week, representative medical men had spoken. Mr. E. B. Turner, who represented the British Medical Association, alleged that it was quite false to say that summer time was bad for children. The additional fresh air which summer time gave the children was a definite benefit to their health, and they were able to see more of their fathers.

A county medical officer of Hants, Dr. R. A. Lyster, was on the deputation, and declared that medical officers of health in school medical officers throughout the country were enthusiastic supporters of summer time because of the evidence of its benefit to health. The Home Secretary claimed that these two strong statements from representatives of the British Medical Association and of the medical officers of health disposed of the objections which had been made about the children.

#### Pensions.

Instructions are being issued to the heads of the various pension areas to continue the practice of giving sessional work on medical boards to medical officers discharged from the medical staff employed by the Ministry.

The convalescent treatment and training centres at Barry and Blackpool were closed during 1924, and the centre at Epsom will be closed this month. The centre at Birmingham is still required, and no date can at present be assigned for its closing.

Colonel Sir Arthur Holbrook, on March 12th, asked the Minister of Pensions whether he would consider the grant of a bonus to ex-service medical officers now in the employ of the Ministry and under notice of discharge in cases where these officers had five years' service or more under the Ministry, seeing that those to be retained were to receive a rise of pay of £50 per annum in lieu of a bonus based on the number of years served. Viscount Curzon replied that it was not customary for temporary civil servants to be paid a bonus on discharge, and the Minister would not feel justified in urging the Chancellor of the Exchequer to grant a special privilege to the temporary medical officers of the Ministry of Pensions. The increase in the pay of the medical officers retained

was not granted in lieu of any such bonus. It had been decided upon as part of a general scheme for the future remuneration of the medical officers of the Ministry, which had been framed after consultation with their staff association.

Mr. Percy Harris asked whether many of these medical officers had not given many years' efficient medical service to the Ministry, and whether it was fair or reasonable, when their services were dispensed with because of decreased work, to throw them out of employment and give them no bonus or gratuity to enable them to find other work. No answer was returned.

Viscount Curzon, on March 12th, stated that a man who, prior to discharge, was found by the military medical board to be suffering from a permanent disability of more than 20 per cent. aggravated by service, would not necessarily be given a pension for life. The worsening by service of the man's pre-existing ailment or injury might be only temporary, and if it were not found to persist the pension could not be continued. He stated also that, subject to the conditions prescribed under the terms of the Royal Warrant, the judgement on which a grant of constant attendance allowance was made to a man was that of his medical advisers.

Viscount Curzon has stated in reply to questions that, although neurasthenic patients undergoing a specific course of treatment were retained in an institution for that purpose, it was not the intention of the Ministry that cases should remain indefinitely or unnecessarily in an institution, and where they could suitably be dealt with by discharge to their homes with an appropriate pension this course was adopted.

**Patent Medicines.**—Mr. Groves asked the Minister of Health, on March 11th, whether he had considered the conditions under which patent medicines were manufactured and sold in this country as compared with other countries; whether he was aware that ill informed persons were attracted by advertisements and thereby failed to obtain proper medical attention; and what steps he could take to ensure public health and safety in this respect. Sir Kingsley Wood said that the question of statutory regulation of the conditions under which patent medicines were advertised was under consideration, but unless a substantial measure of agreement could be secured the Minister of Health did not think it would be possible to introduce legislation in the present session.

**Medical Attendance on Unemployed.**—Mr. Groves, on March 11th, asked the Minister of Health if he had any information on the health of the men and women who had been out of work for two years and upwards, and whether, as such persons might be quite outside the national health insurance benefits, the Minister had considered the issue of instructions to boards of guardians to arrange special medical attention to them. Sir Kingsley Wood, answering for the Minister, said the Prolongation of Insurance Act, 1921, was still in force, and in view of this Act the Ministry of Health had not thought it necessary to make any special inquiries as to the health of unemployed persons. The Minister was not aware that there was any need for the issue of such instructions as Mr. Groves suggested. Mr. Groves asserted that in West Ham a large number of people were outside the scope of the national health insurance scheme, but Sir Kingsley Wood replied that the district medical service was available to them, as to the rest of the community.

**Influenza.**—Sir A. Butti, on March 12th, asked the Minister of Health the number of deaths caused by influenza or its complications in London during January and February, 1925; whether these deaths had any correlation with age, occupation, or locality; and whether, in view of a probable return of the epidemic and its crippling effect on industry, he would consider any amendment of the National Health Insurance Acts to encourage the withdrawal of early influenza cases from factories, workshops, and offices during the most infectious period. Mr. Neville Chamberlain replied that the total number of deaths in London during January and February, 1925, notified as due to influenza was 480, equivalent to 649 per million of the population per annum. Information as to occupations could not be given without a re-examination of the entry relating to each individual death. He thought an amendment of the National Health Insurance Act on the lines suggested would not be practicable. The effect of the Act was already in the direction desired, inasmuch as it encouraged workers to seek prompt medical advice as soon as they began to feel ill, and by providing cash payments during absence from work owing to illness it alleviated the financial loss through such absence.

**Infantile Mortality.**—The Minister of Health stated, on March 11th, that he had received a report from a woman medical inspector on infantile mortality in Market Drayton. It had not been published, but certain suggestions arising out of the report had been sent to the Salop County Council, and he awaited a reply. In the urban district of Market Drayton there had been 77 births in 1924 and 7 deaths under 1 year, or an infantile mortality of 91 per 1,000. In Wellington Urban District there were 135 births and 4 deaths, or 30 per 1,000; in Newport Urban District 48 births and 2 deaths, or 42 per 1,000; and in the county of Salop as a whole 2,119 births and 127 deaths, or 60 per 1,000.

**"Standards" of Lunacy.**—Answering Mr. R. Richardson, on March 12th, the Home Secretary said his attention had not been called to recent remarks of a judge in the High Court reproaching "the tendency of medical experts to set up arbitrary standards of insanity under which almost anybody might be certified insane." The Home Secretary said he was not prepared to introduce legislation entitling a prisoner, who was declared insane by medical experts soon after his conviction, although the issue of sanity had not been raised at his trial, to have a trial of the issue of his sanity in open court under the same conditions as if it had been raised by the defence and contested by the prosecution.

**Medical Referees.**—Mr. Benjamin Smith, on March 16th, asked the Home Secretary whether a medical referee under the Workmen's Compensation Act who is also on the staff of a voluntary hospital was not permitted to give a report on a case under his care at that hospital; and, if so, whether, seeing that this might involve injustice to the patient examined, as no other doctor could know as much of the case, the Minister would consider the advisability of withdrawing the instruction or regulation. Mr. G. Loeker-Lampson (Under Secretary) said no specific Home Office instruction or regulation prevented the doctor in such a case giving the workman or the employer a report on the condition of the workman, but if a referee were employed in any case by or on behalf of either party, he was precluded by the statute from acting subsequently as referee in that case. It was also generally undesirable that referees should act for either party in compensation cases, especially cases which were the subject of dispute. The Home Secretary would, however, consider the matter further, and would be glad to be furnished with the details of any cases which Mr. Smith had in mind.

**Equal Salaries for the two Sexes.**—Miss Wilkinson, on March 17th, asked the Postmaster-General whether he was aware that the Post Office was the only Government department which paid its women doctors less than its men doctors for similar work; and whether, in view of the fact that the Post Office advertisements for posts at present vacant were being refused by the medical journals in consequence, he would bring his department into line with other departments in this matter. The Postmaster-General answered that the conditions under which women medical officers were employed in the Post Office were not analogous with those in other departments. The question of equal pay for men and women was one which affected the whole of the Civil Service, and he was not in a position to recommend an exception in respect of this particular class of civil servant. Miss Wilkinson, in a supplementary question, asserted that the work done by men and women doctors in the Post Office was analogous. The Postmaster-General, correcting his answer, said that one other Government department approximated to Post Office conditions—the Prison Medical Service—and there the payment of men and women doctors was not identical. Dr. Haden Guest asked whether, as the medical papers would not insert medical advertisements from the Post Office, the Post Office had to enter into surreptitious correspondence with certain medical schools to obtain candidates. Did the Postmaster-General think that was dignified? No answer was returned.

**Number and Cost of Asylums.**—Major Glyn asked the Minister of Health, on March 11th, how many asylums for lunatics were under the administration of local authorities now and for the years 1900 and 1914; what was the total number of inmates now and for the same years, and what was the present cost of maintaining these institutions. Mr. Neville Chamberlain said that the cost of maintaining these asylums, excluding loan charges, during the year ended March 31st, 1924, was £2,242,284. On January 1st, 1900, the institutions numbered 79, with 74,014 inmates. On January 1st, 1914, they were 97, with 105,504 inmates, and on January 1st, 1925, 97, with 105,399 inmates. The last figures did not include Ewell Epileptic Colony, lent to the Ministry of Pensions, or the Maudsley Hospital, which provided accommodation for 146 uncertified patients. In answer to another question, the Minister of Health stated that on January 1st, 1925, 111,200 persons were confined in institutions for the insane in England and Wales, of whom 102,315 were maintained at the public expense.

**Ministry of Health.**—Lieut.-Colonel Horlick asked the Minister of Health, on March 12th, how many established medical officers were employed by the Local Government Board in 1914-15 and by the Ministry of Health in 1920; how many established and unestablished medical officers were working for his department at present; and what was the total amount recovered out of the National Health Insurance funds towards the salaries and expenses of regional medical officers. Mr. Neville Chamberlain replied that 34 established medical officers were employed by the Local Government Board in 1914-15, and 73 by the Ministry of Health in 1920. The number of established and unestablished medical officers at present employed was 92. The amount recovered from health insurance funds towards the salaries and expenses of regional medical officers was £36,800 for the current financial year.

**Health Insurance Finances.**—In answer to questions the Minister of Health, on March 15th, gave the approximate total, on December 31st, 1923, of the accumulated funds belonging to all the separate approved societies under the National Health Insurance Act and the statutory funds established from deposit contributors and from persons, not previously insured in societies, serving in the Navy, Army, and Air Force. This total was:

Invested with the National Debt Commissioners ...	£56,000,000
Invested by or on behalf of approved societies ...	£40,000,000
Cash at bank, etc. ...	£2,000,000

The approximate amount of reserve values outstanding at December 31st, 1923, was £105,000,000. In 1912-13 the estimated number of persons entitled to benefit under the National Health Insurance Act was 13,164,000. The contributions were £26,571,000, and the parliamentary votes and grants £26,395,000. In 1921 the persons were 15,134,000, the contributions £25,160,000, and the parliamentary votes and grants £11,757,000. In 1922 the persons were 15,168,000, the contributions £25,002,000, and the votes and grants £8,414,000. In 1923 the totals were 15,037,000, £26,210,000, and £6,940,000 respectively.

**Shortage of Officers R.A.M.C.**—In presenting the Army Estimates, on March 16th, the Secretary for War, Sir L. Worthington-Evans, said he was disquieted by the number of recruits who had been rejected on physical and medical grounds. During the last

recruiting year 49,245 men were rejected—5 out of 8 who presented themselves. Dr. Fremantle, who was prepared with material on army medical topics, was not called on, but Colonel Assheton Pownall drew attention to the position of the Royal Army Medical Corps. The House, he said, did not appreciate the seriousness of the shortage of officers in this Corps. Many the Corps would gladly have kept had resigned in recent years, being dissatisfied with their prospects, and very few had come forward. Of 80 vacancies advertised during the last two years, only 25 had been filled, and during the year ending January 31st, 1925, only one candidate had been gazetted into the R.A.M.C. The total establishment in England and abroad was 884, and the wastage was about 60 or 70 a year. The pay of combatant officers had been greatly increased, while that of R.A.M.C. officers was very slightly more than in 1914. While the pay of captains and majors in the R.A.M.C. was somewhat more than that of the equivalent combatant officers, lieutenant-colonels drew less, if command pay were included. It should be remembered that the combatant officer was gazetted at 19, the R.A.M.C. officer at 24. In the interval up to £2,000 had to be paid, and many parents were not prepared to find this sum in view of the uncertain prospects in the R.A.M.C. The levying of income tax on the extra pay awarded to medical officers who specialized also discouraged them. Civilian practitioners had been doing so much better in recent years, owing, it might be, to the assured position of panel practitioners, that medical men would not run the risk of going into the army. He suggested that the Government should consider making the Director-General of the Medical Service a member of the Army Council. The Secretary of War agreed that the position of the R.A.M.C. had to be looked into carefully. The army was not getting the officers it required, and an undue burden was thrown on those in the Corps. The conditions of medical service in the Navy and in the Air Force would have to be considered at the same time, and he hoped a remedy might shortly be found.

**Bovine Tuberculosis.**—Mr. Hurd asked the Minister of Agriculture, on March 16th, whether, following upon the visit of his scientific advisers to North America, he proposed to adopt in this country such administrative methods for the elimination of bovine tuberculosis as had proved successful in the United States and Canada. Captain Hacking, answering for the Ministry of Agriculture, said the Minister had under consideration means for the elimination of bovine tuberculosis, and he proposed to introduce shortly a measure on the lines of the Tuberculosis Order of 1914, which was a necessary step in any procedure of the kind. [It is understood that the answer of the Ministry of Health forecasting the adoption of "means for the elimination of bovine tuberculosis" does not allude to a curative method, but to the offer of such liberal compensation as would ensure the offer of affected cattle for slaughter. The money cost of this policy to the country will be considerable.]

#### Notes in Brief.

In June, 1921, 11,442 adult workmen were engaged in the manufacture of fine chemicals and drugs in Great Britain. No later figures are available.

During 1923, 14,367 houses in England and Wales were reported as unfit for human habitation.

The Air Ministry has reviewed the American experiments in dropping electrically charged sand from aeroplanes to disperse fogs, but cannot undertake expensive tests of this process, as scientific opinion in England and America is not satisfied with the evidence of success so far given.

The Foot-and-Mouth Disease Scientific Committee expended £5,500 down to February 28th out of £10,000 voted for it in 1924-25. In 1925-26 £15,000 has been assigned to the committee.

No date has yet been fixed by the Home Secretary for the introduction of the Factories Bill.

At the last census of England and Wales 306,000 widows were stated to have dependent children. In respect of 301,000 widows no statement was made about such children. Approximately 55,000 widows with dependent children receive Poor Law relief.

The Minister of Health is anxious to give any help in his power to voluntary societies formed for the reconstruction of insanitary property and the rehousing of the occupants.

The Minister of Health is in communication with the Wednesbury Corporation on the report recently submitted by inspectors of his department about insanitary conditions in the West Bromwich Union, particularly in the parish of Wednesbury.

In reply to Mr. Cadogan, on March 17th, Sir Kingsley Wood said it was not proposed to publish the evidence given before the Departmental Committee on Preservatives in Food, and the Minister of Health did not contemplate setting up a standing advisory committee on food questions.

Sir John Gilmour informed Mr. Maxton, on March 17th, that the discontinuance of the annual grant from Dr. Adam's Agriculture to the Glasgow Veterinary College, the position of that college as a centre, and that the motor car meaning of the Education (Scotland) Act.

Progress is being made, the India C of claim says quite the financial conditions permit, in giving recommendations of the British Station Home anything more than suggest.

The provision of schools and other facilities taken back? children in Scotland has increased, as the words of Mr. Dickinson, not yet available beyond that date, which he secured Mr. Harnett's.

The known blind persons in England, not order Dr. Adam to send for 1923, numbered 36,518. Approximately 20s. a week, with augmentation of information, as a Lord Justice 1924, 11,525 blind persons were receiving pensions under Section

## Correspondence.

### THE PREVENTIVE MEDICINE OF THE EAR.

SIR,—Mr. Somerville Hastings in his article (BRITISH MEDICAL JOURNAL, March 14th, p. 504) makes several assumptions which require to be proved before they can be accepted. I shall, however, confine my attention to only two of these.

How does he know that in any given case medical or surgical interference has arrested the progress of the deafness? Before reaching the conclusion that this can be done a number of carefully recorded cases must be presented accompanied by a number of controls.

What is Mr. Hastings's conception of a normal nose, nasopharynx, and throat? I was more than astonished to read, "but I personally can recall only one case of middle-ear deafness in which the nose, nasopharynx, and ear drums appeared perfectly healthy and in which a clear history of previous trouble in these regions could not be obtained when carefully inquired for."

Does it, then, follow that we are to apply therapeutic measures to every individual who has not, or even has not always had, a normal nose and nasopharynx, in order either to stop the progress of middle-ear deafness or to prevent it from beginning? If so it would seem to follow that nearly the whole population should be under treatment.

I note that Mr. Hastings seems to except certain cases, about which he tells us nothing more than that some have atrophied drum membranes. It is, I admit, not always easy to differentiate advanced middle-ear catarrh from oto-sclerosis, but every otologist has had experience of many typical cases of the latter, and in my opinion nothing can be done by local treatment to influence their progress. Some of them, however, cease to get worse if left to themselves.

It has always appeared to me that the otologist will best add to his own reputation for acumen and honesty by avoiding local interference in typical oto-sclerosis.—I am, etc.,

York, March 16th.

P. McBRIDE.

### ON PLASTIC TONE IN RELATION TO THE HEART.

SIR,—Sir Charles Sherrington's work respecting plastic tone, which has played such an important part in the masterly monograph of the late Dr. J. Irvine Hunter upon the innervation of the voluntary muscles, also supplies a satisfactory working hypothesis to those clinicians who believe that the heart fills itself by its own recoil.

There is one aspect of plastic tone which does not appear to be much emphasized in Sir Charles Sherrington's or Dr. Irvine Hunter's work—namely, that when a muscle fibre is fixed by the onset of plastic tone it becomes an elastic structure and not a rigid one. In other words, when it is exposed to tension or to compression beyond what it is capable of resisting it is distorted by the force applied to it, but returns to its previous length immediately the distorting force has ceased.

Those surgeons who have been fortunate enough during a laparotomy to see the colon hardened and transformed into a tube resembling a piece of thick-walled rubber tubing by the onset of plastic tone will have had this point demonstrated to them. When a spasm of plastic tone passes over a loop of the colon it will rise up as an arch and respond just as a piece of thick-walled rubber tubing would. Blackpool were closed-up loop of bowel is forced down it springs be closed this month. The it is released, or if flattened by and no date can at present be cylindrical again as soon as the Colonel Sir Arthur Holbrook of Pensions whether he would the intervals between the attacks of ex-service medical officers now in will lie flaccid and inert. This under notice of discharge in ex-fibres when in a state of plastic retained were to receive a rise of 10% of describing this type of a bonus based on the number of "elastic fixation." replied that it was not customary his type of activity has another justified in urging the Chancellor that may be called its postural special privilege to the temporary work is concerned it is often of Pensions. The increase in the pay, a spring, so that force may

gradually reach its maximal efficiency rather than that the full strain should be borne suddenly. For instance, when raising water with a force pump the insertion of an air dome (as in a manual fire engine) not only ensures a continuous flow of the water, but also makes more effective the labour of those who are pumping.

In the same way the elastic fixation of the portions of the voluntary muscles which are innervated through the sympathetic system can form a spring against which the voluntary fibres can work, and thus allow of the gradual application of the muscular force when this is desirable, instead of its coming suddenly into play. If this "elastic fixation" were to continue a fraction of a second after the voluntary action ceased it would suffice to restore the limb to the position it occupied prior to the voluntary movement.

In the case of the heart, this theory of elastic fixation readily accounts for the filling of the ventricles. The persistence of elastic fixation for one-tenth of a second after the closure of the semilunar valves is all that is required to ensure that the ventricle fills itself from the blood which has been accumulating in the auricle.

This theory will also meet the objection of those who find no evidence of any expansion phase of cardiac activity in the electro-cardiogram, for there is no need to suppose that the return to its former length of an elastic body which has been compressed would give rise to any change in its electrical reactions. (For the clinical arguments in favour of the ventricles being self-filling see my book *Early Diagnosis of Heart Failure*, pp. 385-441. London: J. Murray.)—I am, etc.,

Birmingham, March 9th.

T. STACEY WILSON.

### THYROID AND MANGANESE AND THE DERMATITIS PRODUCED BY THIAZOLES.

SIR,—The almost simultaneous appearance of two articles, the one on the thyroid and manganese treatment in various diseases (JOURNAL, March 7th, p. 443), and the other on severe dermatitis produced by thiazoles (March 14th, p. 509), stimulates me to make a few remarks.

Manganese I regard as a metal eminently suited to occasion dispersion of the protein particles in the plasma, and the most suitable preparation I have been able to introduce to date is the butyrate. In acute infections and intoxications manganese butyrate does not require to be preceded by a drug, which acts by driving some of the protein particles into solution. This is necessary only in the chronic stage of infectious and intoxications, where some of the protein particles are hydrated already. Depriving hydrated particles of some of their water causes them to become dispersed, and this kind of dispersion is more readily effected by dehydrators than by conductors.

Thyroxin is essentially a dehydrator, and so are the various organic preparations of sulphur I have introduced into medicine. In chronic conditions an injection of iodine or of contramine (CS<sub>2</sub>, product of diethylamine), preferably of both, allows a metal subsequently prescribed to produce many times the degree of dispersion which could be obtained by using the conductor (metal) alone. This was why I have advised for many years the use of iodine and sulphur in all chronic infections and intoxications prior to prescribing the metallic preparations.

Drugs occasioning dehydration of normal protein particles are liable to produce a dermatitis. In fact, it is primarily owing to the protein particles going into solution that the dermatitis produced by organic preparations of sulphur, paraphenylene-diamine and other amino compounds and arseno-benzene is due. When the dehydration is produced by non-metallic substances—of which iodine, sulphur, and amino are the chief offenders—a metallic substance will redress the damage done. Similarly, in metallic intoxication a non-metallic substance is the best antidote. The best example of the latter is arsenical dermatitis, a condition which responds rapidly to daily injections of contramine. This has been substantiated of late by those who recommend sodium thiosulphate. Iodine dermatitis is met with in iodoform poisoning, and amino dermatitis in paraphenylene-diamine poisoning (fur dermatitis). Both these conditions vanish the moment manganese butyrate is injected. Organic preparations of sulphur cause various

forms of dermatitis, from the simple erythema to the severe burns witnessed in mustard-gas poisoning. In all of these manganese butyrate is of value. But in the most severe it is not sufficiently powerful. Recent work has shown me that a better conductor effect can be produced by the liberation of sodium and hydrogen atoms from a highly complex substance than can be obtained with any preparation of manganese at present available. In other words, some of the severe cases of sulphur dermatitis respond better to certain complex symmetrical urea compounds, which I am introducing as therapeutic agents, than to organic compounds of manganese.

As there is no fundamental difference between the action of non-metals and micro-organisms, it is understandable why metallic preparations are valuable therapeutic agents in the acute stage of infections.—I am, etc.,

London, W., March 13th.

J. E. R. McDONAGH.

#### CARE OF CRIPPLES.

SIR,—Mr. Hey Groves has dealt with the subject of poliomyelitis in his usual lucid manner (March 14th, p. 492), but the latter part of his article seems hardly to give credit for the great advances made in recent years in the co-operation of the voluntary hospitals with local education and tuberculosis authorities and other agencies charged with the care and cure of the crippled child.

Until recently his strictures were more than justified, but since the war great efforts have been made to put the after-treatment of cripples on a scientific and secure basis. Originated at Baschurch, and developed in Oxford, there are few counties in England now that are not engaged in the organization of after-care.

For London and the Home Counties there already exists a voluntary organization for dealing with the type of case that Mr. Hey Groves has in mind. This is the Royal National Orthopaedic Hospital with its 200 beds in Great Portland Street, and its new rural branch of over 100 beds, with the immediate prospect of a further 200, at Stanmore, Middlesex. This country hospital, which stands on gravel soil on the top of Brockley Hill, 450 feet above sea-level, is ideally situated for its purpose. It is only ten miles from the Marble Arch in a straight line along the Edgware Road, and a mile and a half from the Hampstead tube terminus at Edgware.

Plans have been prepared for the addition of another 200 beds with new theatre and treatment blocks and full artificial sunlight equipment. The site of 30 acres allows for any necessary future extension up to as many as 600 or even more beds. Arrangements for in-patient treatment are in operation with the Loudon County Council and the Hertfordshire and Middlesex County Councils, as well as with many other local educational and tuberculosis authorities.

A scheme of clinics for after-care and treatment is already in being in Hertfordshire, and these clinics are being visited periodically by one of the surgeons of the hospital. Negotiations for a similar arrangement are in progress between the hospital and other county local authorities.—I am, etc.,

Royal National Orthopaedic Hospital,  
Stanmore, March 16th.

J. B. BARNETT,  
Resident Medical Officer and  
Surgical Registrar.

#### ISOLATION HOSPITALS AND SCARLET FEVER.

SIR,—I have purposely refrained from entering into the controversy on the value of the method introduced by my father for the prevention and treatment of scarlet fever and measles; but I cannot pass, unchallenged, a statement made by Dr. Burton (March 14th, p. 531) that this method has been discarded in the home of its birth. That is not so. In the hospital and homes which are under my care the Milne method has always been, and is still being, used with satisfactory results and absence of complications.

I would refer Dr. Burton to the experiences of other medical officers of health at Edinburgh, Forfar, Clydebank, Tottenham, Southgate, Heston and Isleworth, Castleford, and other places.

The statements made both by Dr. Gusline-Taylor and by Dr. Burton, alleging that the swabbing of the throat with

10 per cent. carbolic oil is harmful, are also inaccurate. I have used it personally and for my patients (children of all ages) for over twenty years, and have seen none but the most beneficial results; it is both analgesic and antiseptic, and I have never seen any harm result from its use.—I am, etc.,

March 14th.

JAMES A. MILNE,  
Joint Medical Officer,  
Dr. Barnardo's Homes and Hospitals.

#### HEART STRAIN.

SIR,—I appreciate the interest Dr. E. S. Miller has taken in my paper on heart strain (March 7th, p. 482), challenging though he does a theory expressed in it. I am not, however, persuaded by his letter that the principle of the Bramali press is not applicable to the force acting on the left ventricle in aortic incompetence; but I will not occupy your space by arguing what is chiefly a scientific point.

I think all agree that, whatever the reason, aortic incompetence is the most serious of valvular diseases and the one most likely to cause sudden heart failure.—I am, etc.,

Manchester, March 16th.

E. M. BROCKBANK.

#### "WEMIC."

SIR,—I should be greatly indebted to you or to any of your historical contributors if I could be informed of the meaning of the word "wemic." It occurs in some fragmentary depositions remaining in the bishop's registry at Chester. It is evidently a surgical affection of an urgent, life-and-death character, for which the mediaeval surgeons operated, as the testator was "cutt of a wemic and in dauuger of death." But he was clear in his mind and talked to those about him, and gave instructions concerning his will. A "phisicon" and a surgeon were present, and the former deposed that "Testator had undergone an operation just before executing his will, and died a few hours after." The date is 1574. "We..." is not yet out in the N.E.D., so that source of information is not available. I am familiar with the word "wem."—I am, etc.,

Liverpool, March 13th.

F. CHARLES LARKIN.

#### Medico-Legal.

#### LUNACY LAW AND ADMINISTRATION.

HARNETT v. BOND AND ADAM.

THE hearing by the House of Lords of the case Harnett v. Bond and Adam—the commencement of which was reported in the BRITISH MEDICAL JOURNAL last week (p. 533)—was continued on Thursday, March 12th.

Mr. Cope Morgan, for the appellant, was arguing that Dr. Bond was not only responsible for the three hours' detention in the Commissioners' office in Victoria Street, London, but also for the taking of Mr. Harnett back to Dr. Adam's mental home at Malling Place, when Lord Atkinson asked:

If Dr. Bond induced Dr. Adam to take Mr. Harnett back, and Dr. Adam took him back, whose act was it?

Lord Dunedin: And, if one Scotsman said to another, "That's good whisky," and the other drew the cork, whose act was it that drew the cork?

Lord Buckmaster: It was Dr. Adam who ordered his two servants to take Mr. Harnett back, and all Dr. Bond did was to give Mr. Harnett over to the two servants. It was not Dr. Bond but Dr. Adam who took him back.

Mr. Cope Morgan: But the jury found that Dr. Bond did cause Mr. Harnett to be taken back.

Lord Dunedin: And we say, Let the jury answer as they like. There is no evidence on which they can so find.

Lord Buckmaster: And Mr. Harnett's unlawful detention ceased from the moment Dr. Adam's own servants, under Dr. Adam's orders, took him back into Dr. Adam's care.

Mr. Cope Morgan: But the jury found that the motor car journey was the act of Dr. Bond.

Lord Buckmaster: Your statement of claim says quite the opposite.

Lord Atkinson: Did Dr. Bond do anything more than suggest to Dr. Adam that Mr. Harnett should be taken back?

Mr. Cope Morgan: Dr. Bond, in the words of Mr. Dickinson, used "gentle persuasion" by which he secured Mr. Harnett's return into the hands of the keepers.

Lord Atkinson: Dr. Bond did not order Dr. Adam to send for Mr. Harnett?

Mr. Cope Morgan: Dr. Adam's information, as a Lord Justice put it, came from a source which was authoritative.

Lord Atkinson suggested that it would be highly reprehensible on the part of Dr. Bond if he formed an opinion that Mr. Harnett was excited and looked in a dangerous condition and yet did nothing. If Mr. Harnett appeared excited and not completely recovered, therefore the best thing to do was to take him back.

Lord Buckmaster (to Counsel): You will assume that Dr. Adam accepts Dr. Bond's opinion as to Mr. Harnett's condition. Dr. Adam, surely, knew perfectly well that Dr. Bond was sitting in those offices as a Commissioner? What happened is this: The jury found that Dr. Bond believed that Mr. Harnett had escaped from the custody of his brother. Mr. Harnett had addressed Dr. Bond in such an excitable manner that Dr. Bond found a difficulty in following what Mr. Harnett was saying. On these facts, was not Dr. Bond justified in pointing out to Dr. Adam, the legal custodian of the man: Be careful; this man is out, and you had better take him back again? What was Dr. Bond to do else? Was he to send for a specialist from Harley Street?

Mr. Cope Morgan: Mr. Harnett told Dr. Bond the simple story of what had happened to him.

Lord Buckmaster: But did it seem a plain, simple story, or did it appear to be continued excitement in the man? On these facts, I do not really know what Dr. Bond was to do? There were three courses: (a) let him go; (b) do what he actually did; (c) ask him to see an eminent physician and take a further opinion at his own expense.

Mr. Cope Morgan: There was no indication of excitement in Mr. Harnett's mind then.

Lord Buckmaster: If he came in as a plain, sensible person, why should Dr. Bond do what he did? Whatever induced him to? If a servant came to you in your house one day and said: "There is a man in the house in great excitement; he seems mad; what are we to do?" It is certain what you would say: "Keep him here and telephone to where he has come from."

Mr. Cope Morgan: If I had done that, and sent a record of what I had done to the doctor, it would be childish to argue that anything I had done was of the same significance.

Lord Buckmaster (interrupting): All he had done was something wrong in detaining him.

Mr. Cope Morgan: In such a case it would be childish to say I had procured the mind of the doctor; but it is otherwise here.

Mr. Cope Morgan submitted that their lordships could not view Dr. Adam's act as independent of the action of Dr. Bond. On the facts, Dr. Bond must be regarded as the direct cause of the wrongful detention that night by Dr. Adam.

Mr. Cope Morgan, at the commencement of Friday's hearing, said that Mr. Harnett had withdrawn his instructions, but, after leaving the House for a short time, he said that that withdrawal had since been revoked. Continuing his argument, Mr. Cope Morgan said that Dr. Adam had not acted with reasonable care, and there was evidence upon which the jury's finding to this effect could be justified. Mr. Justice Lush had said that it was for Dr. Adam, under the authority given by the Reception Order and the Leave of Absence Order—made under Section 55 of the Lunacy Act, 1890, and containing the proviso, sanctioned by the Law Officers at a later date, that the patient should be taken back "if his mental condition requires it"—independently to decide whether Mr. Harnett's condition required his being taken back. Assuming that the statute did give Dr. Adam power to go out and recapture Mr. Harnett then counsel contended it must be a condition precedent to the exercise of that power that Dr. Adam should exercise an independent opinion. The proviso "if his mental condition requires it" meant what it said, and since, as a fact, Mr. Harnett's mental condition did not require it, then Dr. Adam had no more authority to arrest Mr. Harnett than an ordinary person had power to arrest another person on the supposition of crime.

Lord Atkinson: But who else was to decide under the Reception Order? How was he to be got back? What is to be done? If he is not to take him back under the old Reception Order and Leave of Absence Order, must he get a new order, or must somebody else bring him back there?

Mr. Cope Morgan: Of course, Dr. Adam could have taken him back if somebody else brought him there. Dr. Adam's whole authority under the Lunacy Act, as a proprietor of a licensed house, was to receive and keep a man under a reception order; he had no extramural authority.

Lord Sumner: Would you say, in those circumstances, Section 330 of the Lunacy Act, 1890, would not apply?

Mr. Cope Morgan replied that in respect of the first part of the detention the jury had found that Dr. Adam had not acted with "reasonable care," which was a condition precedent to the application of the section.

Lord Dundee: Then, in your view, for the time occupied by the motor-car drive before Dr. Adam exercised his judgement, you should get damages—just for an hour's motor drive?

Mr. Cope Morgan said damages for an hour's motor journey may be substantial if the direct object of the journey was incarceration in a lunatic asylum.

The Lord Chancellor: What were the grounds of the finding that Dr. Adam did not exercise reasonable care?

Mr. Cope Morgan: (1) That Dr. Adam did not go to the offices of the Commissioners himself; (2) that he did not even send his assistant, Dr. Gray.

Lord Atkinson: Tell me how he was to be brought back?

Mr. Cope Morgan: The whole charge was that Dr. Adam brought Mr. Harnett back without seeing him. The third ground was that this act of Dr. Adam did harm to Mr. Harnett.

The Lord Chancellor: It is not want of care because he did harm.

Lord Buckmaster: What other grounds besides not going himself and not sending his assistant?

Mr. Cope Morgan: The fourth ground is that, in the circumstances, Dr. Adam admitted that this motor journey necessitated keeping Mr. Harnett detained for two hours before the car arrived.

The Lord Chancellor: It amounts to this: Dr. Adam did not go himself and did not send Dr. Gray.

Mr. Cope Morgan: The fifth ground is that Dr. Adam did not explain to Dr. Bond that he had wholly misled Dr. Bond as to the terms on which Mr. Harnett was out. Dr. Adam did not ask the question which would have revealed the true situation.

Mr. Cope Morgan pointed out that the jury had found that although Dr. Adam honestly believed Mr. Harnett was unfit to be at large yet they did not think he had exercised reasonable care because he had not himself gone to London to see whether Mr. Harnett's mental condition did require his being brought back.

Lord Buckmaster said if a man honestly believed the patient was unfit to be at large, and that it was in the patient's interest to be brought back, and he sent for the patient to be brought back, it was sufficient for the purposes of Section 330 if he showed that the internal arrangements of the asylum would have been interfered with if he had gone himself.

Mr. Cope Morgan: Where a defendant takes upon himself to say that the reason why he did not go was because his assistant had an afternoon off?

Lord Buckmaster: It was a Saturday afternoon, and if a man said how he spent an afternoon twelve years ago without anything to refresh his memory I should doubt his accuracy.

Mr. Cope Morgan: But the jury found he did not exercise reasonable care. He brought Mr. Harnett back and formed his opinion afterwards, instead of forming his opinion prior to bringing Mr. Harnett back. Then, also, when on the telephone to Dr. Bond, Dr. Adam was plainly negligent. Mr. Harnett had not been seen by them.

Lord Buckmaster: They must have seen him, else they could not have said on the telephone that Mr. Harnett was in an excited condition.

Mr. Cope Morgan: Dr. Bond said Dr. Adam told him Mr. Harnett had been allowed out on a Leave of Absence Order in the care of his brother. Dr. Adam then said, "Then he has escaped from his brother? Very well; I will send a car."

Lord Atkinson: He escaped from his brother and went expressly to the Commissioners to get released from his brother's care.

Mr. Cope Morgan: Dr. Adam made a crucial mistake in not going on with the conversation.

Lord Buckmaster: He said he did, but he could not remember what he said as it was twelve years ago. The whole point is whether this statement of Mr. Harnett's to Dr. Bond was made before or after the telephone message.

Mr. Cope Morgan: The memorandum of Dr. Bond says it was made afterwards.

The Lord Chancellor: But he also said there may have been two telephone messages.

Mr. Cope Morgan reiterated that the jury had found that Dr. Adam had not exercised reasonable care.

Lord Buckmaster: You keep introducing "reasonable care." Supposing Dr. Adam was informed by credible authority that Mr. Harnett was not fit to be at large, surely the statutory obligation of reasonable care is satisfied.

Mr. Cope Morgan concluded his argument on Monday afternoon, and Mr. J. W. Morris, who followed, in a brief address to the House, submitted that if Mr. Harnett had suffered physical injuries as the result of the false imprisonment he would have recovered damages. Surely, then, as he had suffered physical injuries in the shape of severe nervous shock as the result of false imprisonment, he ought to be awarded damages.

#### Decision of the House.

At the conclusion of the arguments of appellant's counsel, the Lord Chancellor announced that their lordships did not desire to hear counsel for either of the respondents. They were unanimously of opinion that the Court of Appeal had arrived at the right conclusion. But in view of the general importance of the questions raised by the appeal their lordships would take time to enable them to put their reasons for their decision in writing.

## The Services.

### ROYAL NAVAL MEDICAL SERVICE. COMPASSIONATE FUND.

A MEETING of the subscribers of the Naval Medical Compassionate Fund will be held at 11.30 a.m., on April 17th at the Medical Department of the Navy, 68, Victoria Street, S.W.1, to elect six directors of the fund.

## WAZIRISTAN OPERATIONS.

THE following appointments to the Order of the British Empire are announced in connexion with the military operations in Waziristan, April, 1923, to March, 1924:

O.B.E. (Military): Major Charles Herbert Stringer, D.S.O., R.A.M.C.  
M.B.E. (Military): Captain Ambuj Nath Bose, I.M.S., Captain Henry Hawes Elliot, M.C., I.M.S.

The following officers have been brought to notice for distinguished services during the Waziristan operations:

Royal Army Medical Corps: Major C. H. Stringer, D.S.O., Captain D. G. Gripper, Captain D. C. Scott, O.B.E.

Indian Medical Service: Captains T. R. Birmani, O. M. Ganapathy, M.C., D. V. O'Malley, O.B.E., M. V. Pathak, B. Prasad, and R. V. Rau.  
Indian Medical Department: 2nd Class Assistant Surgeon G. H. Mason.

## Universities and Colleges.

## UNIVERSITY OF OXFORD.

THE appointment of Mr. Kenneth J. Franklin, M.A., B.M., Fellow of Oriel College, to be demonstrator in the department of pharmacology, has been approved by Convocation.

## UNIVERSITY OF CAMBRIDGE.

AT a congregation held on March 13th the following medical degrees were conferred:

M.D.—C. R. Crowther, J. W. Tonks.  
M.Chir. and M.B.—G. L. Thompson.  
M.B.—A. H. Johns, J. O. Ainsworth-Davis.

## UNIVERSITY OF LONDON.

## ELECTION TO SENATE.

WE stated a few weeks ago (February 28th, p. 434) that Sir Lenthal Cheate was opposing Sir Holburt Waring as representative of the Faculty of Medicine on the Senate and mentioned the chief motives by which he was actuated. In his address Sir Holburt Waring dealt with most of the points raised by his opponent. He was, he said, in favour of the removal of the administrative offices of the University, the examination halls, and the libraries from their present lodgings in a portion of the Imperial Institute buildings to a central site. He was not in favour of centralizing all the colleges and institutions for teaching and research on the Bloomsbury site, even were that possible, which it was not. He stated further that he did not advocate incorporation of any of the medical schools into the University, but desired each to retain its autonomy. He did not accept Sir Lenthal Cheate's view that the smaller schools of the Faculty of Medicine should be represented upon the Senate, but held that the representatives of the Faculty should represent the interests of all teachers in that Faculty, and not the interests of institutions. He also expressed the view that his opponent had wrongly stated the purpose of the departmental committee now sitting; that committee was instructed, having regard to present circumstances and after consultation with the persons and bodies concerned, to indicate what are the changes now most needed in the existing constitution of the University, and on what basis a statutory commission should be set up to frame new statutes for the University.

Sir Holburt Waring was re-elected by 66 votes to 57.

## UNIVERSITY OF GLASGOW.

THE late Dr. John Hall, St. John's Wood, London, who died in 1909, left in reversion the half of his residuary estate to the University of Glasgow for the endowment of certain tutorial fellowships in medicine, surgery, and midwifery, and for the better equipment of practical instruction in these subjects. The reversion has now accrued by the death of his sister, Miss Hall, who has left half of her estate for the augmentation of her brother's benefaction. The endowment will in all amount to some £50,000, but some months must elapse for the realization of the estate and for the elaboration of a scheme for its application to the purposes designated.

Professor J. S. Haldane, M.D., LL.D., F.R.S., Fellow of New College, Oxford, has been appointed Gifford Lecturer for 1926-27.

## UNIVERSITY OF DUBLIN.

## TRINITY COLLEGE.

THE Senate of Trinity College has approved graces for the following honorary degrees to be conferred on medical men:

So.D.—Sir Frederick G. Hopkins, F.R.S.  
M.Ch.—Profesr G. W. Crile and Dr. Charles H. Mayo.

## ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary Council meeting was held on March 12th, when the President, Sir John Bland-Sutton, was in the chair.

## Court of Examiners.

Mr. Arthur Percy Dodds-Parker was admitted a member of the Court of Examiners.

## Medals.

Mr. Richard Higgins Burne was presented with the honorary gold medal of the College, together with a document declaratory of its award to him, for his valuable services to the College as curator of the physiological department of the museum and his important contributions to biological science. Mr. Wilfred Le Gros Clark was presented with the John Hunter medal in bronze and a cheque for £50, the amount of the triennial prize for 1922-24, awarded to him for his researches in anatomy.

## Diplomas.

The diploma of M.R.C.S. was conferred upon V. A. Edge and Gladys E. McCabe, who had passed the requisite examinations and had now complied with the by-laws.

## Dental Surgery.

Licences in dental surgery were granted to 82 candidates. A recommendation from the Board of Examiners in Dental Surgery was approved and adopted to the effect that, "so long as the examinations for the licence are held three times a year, the interval required by the regulations between the first and second professional examinations be reduced from six to four months."

It was decided to appoint two additional members of the Dental Section of the Board of Examiners in Dental Surgery. Particulars regarding the sending of applications will be announced in the medical journals on April 18th.

## Appointment of Representatives.

Mr. James Sherren was reappointed to represent the College on the Senate of the University of London for the period from May next to May, 1929.

Dr. W. S. A. Griffith was reappointed to represent the College on the Central Midwives Board for the period of one year from March 31st, 1925.

## Gifts.

The Wellcome Historical Medical Museum presented some photographic reproductions of illustrations from the *Life of John Hunter*, by Jesse Foote, Surgeon, London, 1794, which were accepted with the best thanks of the Council.

An oil painting, believed to be by Gainsborough and to represent John Hunter, was presented by Mr. G. Buckston Browne, M.R.C.S., and accepted with thanks.

## Anatomical Subjects.

A conference with the licensing bodies, medical schools, and services regarding the present inadequate supply of "subjects" for teaching, examinations, and research was held at the College on Tuesday, March 17th.

## COUNCIL ELECTION.

Monday, March 16th, was the last day for the receipt of nominations of candidates for the Council. The three retiring members, Mr. Warren Low, Mr. James Sherren, and Sir John Lynn-Thomas, seek re-election, and the following four candidates were also nominated: Mr. Herbert James Paterson, Fellow 1837, Mr. Arthur Burgess, Fellow 1899, Mr. Victor Bonney, Fellow 1899, and Mr. John Percy Lockhart-Mummery, Fellow 1900.

The composition of the Council since July, 1924, is as follows:

President.—Sir John Bland-Sutton, Council (1) 1910, (2) 1918; Pres. 1923 and 1924.

Vice-Presidents.—Sir Holburt J. Waring, O.B.E., O. (1) 1913, (2) 1921; Mr. Walter George Spencer, O.B.E., O. (1) 1915 (substitute), (2) 1918.

Other Members of Council.—Sir Anthony Bowlby, Bt., K.C.B., K.C.M.G., K.O.V.O., O. (1) 1904, (2) 1912, (3) 1920, Pres. 1921, 1922; Sir Charles Alfred Ballance, K.O.M.G., O.B., M.V.O., O. (1) 1910, (2) 1914, (3) 1922; Sir D'Arcy Power, K.B.E., O. (1) 1912, (2) 1920; Sir Berkeley George Andrew Moynihan, Bt., K.O.M.G., O.B., O. (1) 1912 (substitute), (2) 1919; Mr. Vincent Warren Low, O.B., O. ## Obituary.

### MARY DARBY STURGE, M.D.LOND.,

Physician to the Birmingham and Midland Hospital for Women.

MISS MARY DARBY STURGE, whose death on March 14th we have the great regret to record, was born at Edgbaston in 1862.

She came of a family distinguished for its practical adherence to the principles of the Society of Friends. Her father, Wilson Sturge, is still held in memory in Birmingham, not only as mayor, which office he filled in 1862, but because he devoted the greater part of his life to the furtherance of peace. Her paternal great-uncle, Joseph Sturge, was an outstanding supporter of all movements which had for their object the improvement of conditions for mankind. Among these were the abolition of slavery, and the cause of temperance.

Miss Sturge was educated at Edgbaston High School for Girls during the wise headship of Miss Cooper. When the Mason Science College (Birmingham University) was opened in 1880, Miss Sturge was one of the first small group of regular women students. In 1886 she passed the preliminary scientific examination of London University.

After this an application was made for herself and another woman student to enter the Medical School at Birmingham. This was refused, though the hospitals assented, but Miss Sturge studied physiology for a year at Mason College.

In 1886 she entered the London School of Medicine for Women. There she took prizes in anatomy and physiology and became demonstrator in the former subject. Her student career was distinguished throughout; she took honours in anatomy in the intermediate M.B. examination and honours in medicine in the final M.B. She gained the Prideaux Scholarship for an original paper on clinical obstetrics.

After taking her degree, Miss Sturge was for six months resident at the Clapham Maternity Hospital, and at the same time acted as physician to the Dispensary for Women and Children. For two years from 1892 she was resident at the North-Eastern Fever Hospital, and afterwards senior resident at the New (now Elizabeth Garrett Anderson) Hospital for Women. In 1895 she took the M.D.Lond., and began general practice at Edgbaston, where she worked for the rest of her life. From 1895 to 1905 she served the Birmingham and Midland Hospital for Women as anaesthetist, and for nineteen years as honorary physician, resigning the latter appointment in 1924. Miss Sturge was also secretary to the Medical Board of that hospital for eleven years.

She found time for many interests outside her practice. At the opening of the winter session in 1894 at the London School of Medicine for Women, Miss Sturge gave a stimulating and helpful inaugural address. During the years 1920 to 1922 she was the first provincial president of the Medical Women's Federation, and took much interest and pleasure in the work entailed by this office. But probably that by which she will be best remembered, not only among members of the profession but by the general public, is the book *Alcohol and the Human Body* (1907), which was the result of the joint efforts of the late Sir Victor Horsley and herself. Probably they were moved to write the book by the result of the petition signed in 1904 by thirteen thousand members of the medical profession, and addressed to the Board of Education, advocating the teaching of temperance in schools. The facts given in this work were carefully collated, and no book has had more influence in forwarding the cause of temperance. Another side of Miss Sturge's character was revealed in her great love of children, and her interest in all that pertained to their

upbringing and education. Long before the idea was generally accepted that sunlight and fresh air were two of the chief essentials for healthy childhood, Miss Sturge was practising and preaching this principle.

One of her recent enterprises was the founding of the Birmingham Taylor Memorial Home for Inoperable Cancer. Her plea was that every healthy woman should contribute to the amelioration of these tragic cases. Miss Sturge was always generous to all funds for the distressed, especially those for the benefit of children. Her poorer patients knew her practical generosity, as also did any "concern" of hers, as she phrased it in the language of the Friends. Miss Sturge was one who upheld the noblest ideals of the profession. She was an indomitable worker, and never spared herself, especially where she thought her professional knowledge could help her fellow creatures to fight and overcome what her religious principles regarded as evils. In fact, a verse of Whittier written after the death of Joseph Sturge, with a slight transposition, might well have been written of her:

"The very gentlest of all human natures  
She joined to courage strong,  
And love outreaching unto all God's creatures  
With sturdy hate of wrong."

Mr. J. FURNEUX JORDAN, F.R.C.S., sends us the following appreciation: Dr. Mary D. Sturge was for

many years on the staff of the Birmingham Hospital for Women, resigning last year after over twenty years' service. I had the privilege of working closely with her during that time, and I can truthfully say that no patients ever had a kinder, more sympathetic, more helpful doctor than hers. Self-sacrifice was the keynote of her life. She never spared herself in the endeavour to help others. In many ways she was a pioneer. Apart from being the doyen of the women doctors in Birmingham, and loved by all of them, she had the soul and the spirit of an originator. She was always wanting something better for others, and it was this spirit that made her devote every minute of her life not occupied by medicine to various forms of social reform. The profession, and especially the ranks of the women doctors, is the poorer for her loss.

MARY DARBY STURGE, M.D.

Dr. JANE WALKER writes: There are many people besides myself who deeply regret the passing of Dr. Mary Sturge. She and I of late years have done a great deal of work together. She was one of the keenest workers for the Medical Women's Federation, and helped devotedly with its constitution and organization from its inception. We did not always see eye to eye, but our differences perhaps made us better friends; certainly they sharpened our wits. Dr. Sturge was every inch of her a Quaker, but she was not exactly of the "turn the other cheek" brand. She was a keen fighter, and indeed the phrase which sounds like a contradiction in terms—namely, "fighting pacifist"—would, I am sure, in the opinion of those who knew her best describe her. But her fighting was never for her own hand, but was directed steadfastly against wrong-doing and wickedness wherever she felt they were to be found. She is perhaps best known for her work in the cause of temperance, in which she collaborated with the late Sir Victor Horsley in the production of *Alcohol and the Human Body*, a book which has run through many editions. But she was a great worker for the promotion of purity and of a cleaner social life. She served on a committee which dealt with the prevention and cure of venereal disease, where her Quaker tradition and convictions showed her plainly how futile and harmful were all methods of compulsion applied to the problems which surrounded the control of these diseases. Such a fine unselfseeking character will be very greatly missed, and the world is indeed much poorer for her loss.

Dr. L. MARTINDALE writes: For many years before I had the privilege of her friendship Dr. Sturge's name was familiar to me. Her courageous stand in the cause of temperance, her work in connexion with legislation dealing with many social problems, and the eminent position she took in the medical profession as president of the Medical Women's Federation make her stand out amongst those women leaders who had left behind them a great name and a great life's work. She was fearless and so generous herself that she took it for granted that everyone, rich or poor, would esteem it a privilege to help in any of her pet schemes. This confidence was rarely misplaced, and many unlucky, unsuccessful protégées of hers owe her much for the help she gave or procured to enable them to make a fresh start in life. Her generous, unselfish spirit showed itself most of all in the encouragement and help she gave to her own colleagues. She was always endeavouring to procure more openings for medical women, more honorary appointments on hospital staffs, and more resident appointments for the junior members of the profession. Professional jealousy was unknown to her, and this probably accounts for the real affection she received from men and women alike, whether they were her medical colleagues, or her patients, or the patients' friends. Her uprightness and wisdom in dealing with her fellows, her moral courage and fearlessness and untiring energy, and but some of the qualities which will remain in many of our memories as the characteristics which endeared Dr. Mary Sturge to those of us who counted her as our friend.

JOHN CLELAND, M.D., D.Sc., LL.D., F.R.S.,  
Emeritus Professor of Anatomy, University of Glasgow.

THE death took place on March 5th, at Chatham, of Dr. John Cleland, Emeritus Professor of Anatomy in the University of Glasgow, in his 90th year. He had recently removed from Crewkerne, in Somersetshire, where he had spent the greater part of his leisure since his retirement from university duties in 1909. Owing to the long period of sixteen years that had elapsed since his retirement from the chair in Glasgow, he had become little more than a distinguished tradition to the present generation of students, although many men now in medical practice owe to his teaching and to the stimulus of his writings their grounding in medical science.

John Cleland was born at Perth on June 15th, 1835; his father was a medical practitioner in that city, but died at an early age. His widow, having removed to Edinburgh, set herself with devotion to the training and education of her two sons, and young Cleland received his early education in the High School, and afterwards entered the University in 1851 to study medicine. There he came under the influence of Professor John Goodsir, and from that time onwards study, teaching, and research in anatomy became the chief occupations of his life. He completed his medical curriculum at Edinburgh University at the age of 20, and spent a year in France and Germany, continuing his medical studies before he reached the age at which graduation was permissible. For several years after graduation he remained in Edinburgh as assistant in the anatomical department, and thereafter was associated as senior demonstrator with Professor Allen Thomson in Glasgow. In 1863 Dr. Cleland was appointed to the combined Chair of Anatomy and Physiology in Queen's College, Galway, a post which he held for fourteen years. At this period of his life he not only engaged in professorial duties, but practised also as surgeon to the hospital, and during this time many of his papers were written. While he was at Queen's College he published *Animal Physiology* (1874) and a *Directory of Dissection* (1876). At this time also he acted as joint editor of the seventh edition of *Quain's Anatomy*, which was brought out in 1867, and he was engaged in numerous minor writings which were subsequently published in 1881 as a volume of essays entitled *Evolution, Expression, and Sensation: Cell Life and Pathology*.

When Professor Allen Thomson retired from the Chair of Anatomy in Glasgow in 1877 he was succeeded by Dr. Cleland, who continued for over thirty years in uninterrupted tenure of the chair. During this period he was one

of the most outstanding figures in medico-scientific circles in Scotland. He was a great personality in the University of Glasgow, and many students were deeply influenced in their modern biological conceptions by his teaching. Far from being only a man of science, his nature possessed a broad artistic side, and he was endowed with no mean gifts as a poet and painter. Some of his poems were published in a volume, *Scala Naturae*, in 1887. Early training under Professor Goodsir had given Cleland's mind a special bent in the direction of the problems of morphology, and he has left a large quantity of original work, partly of the nature of detailed research, and partly of philosophical criticism and speculation, bearing upon such problems. As an evolutionist he had a great regard for the work of Darwin. He adopted, however, an attitude of strong opposition to the materialism which he believed would be the inevitable outcome of entire acceptance of the theory of natural selection as the principal law of evolution. For many years among scientific men he stood almost alone as an expositor of the spiritualistic conception of life.

Throughout his tenure of the chair in Glasgow he devoted himself as assiduously to teaching as to research. An improved volume of *Memoirs and Memoranda in Anatomy* was issued by him in 1889 from the Anatomical Department of Glasgow University, and his textbook of *Human Anatomy*, published in association with Dr. Mackay in 1896, was highly popular with students and contained a record of many original observations which had been gathered by him during his long period of work as a professor.

In addition to the M.D. of Edinburgh, which he took in 1856, the Universities of St. Andrews, Edinburgh, and Glasgow each conferred upon him the honorary degree of LL.D., and the Queen's College University of Ireland that of D.Sc.

Personally he was a man of alert, quick, and sensitive temperament, with strong feeling and wide interests. Besides his interests in teaching, research, and artistic pursuits, he carried out a great deal of hard work in building up, and enriching the splendid anatomical museum which he has left in the University of Glasgow, and which forms a valuable complement to the Hunterian Museum there. Among those who knew him he will be remembered as a man of deep learning, lofty ideals, and unwearied energy which preserved the spirit of youth throughout a long career.

A year after the death in 1887 of his mother, to whom he was deeply attached, he married the eldest daughter of the late Dr. John Hutton Balfour, Professor of Botany in the University of Edinburgh, and sister of Sir Isaac Bailey Balfour. She predeceased him in 1918. There was one son of the marriage. The funeral took place at Golders Green Crematorium on March 7th, and the ashes were interred in Crewkerne Cemetery, Somersetshire.

Dr. HUGH EDWARD WINGFIELD, who died on March 4th at his residence in Bedford Park, was educated at Haileybury, Caius College, and St. George's Hospital; he graduated M.B., B.Ch. in 1895, and proceeded M.D. in 1898. He was for some time demonstrator in physiology in Cambridge University, and took up the study of hypnosis. He also held the appointment of house-physician to the Royal Free Hospital. Later he practised in Winchester, and was appointed medical officer to Winchester College and consulting physician to the Royal Hants County Hospital. He was an ex-president of the Psycho-Medical Society and ex-president of the Medical Officers of Schools Association. He published two books—*An Introduction to the Study of Hypnotism* and *The Forms of Alcoholism and their Treatment*; he also contributed articles to the *BRITISH MEDICAL JOURNAL* and other periodicals on the subjects of psychology and alcoholism. He took a keen interest in chess, and was president of the Winchester Institute Chess Club, to which he presented a challenge cup and silver knight for which there is an annual competition. F. H. E. writes: Wingfield, when at Cambridge, had a wonderful power of hypnotizing fellow undergraduates, which he exerted sometimes for scientific, sometimes for amusing ends. His influence was often for good, as the following story shows. A student reading for the theological tripos was wasting his time in various harmless but unworthy ways. Wingfield hypnotized

him and, unknown to the sitter, told him that he must work two hours a day; this he did, though often not beginning until near midnight. He passed his examinations with credit. Many years later I asked Wingfield whether this student had done well. "Yes," was the reply, "I met him a year or two since in the Strand—a fat, prosperous, contented clergyman, up from the country, who said, 'I turned over a new leaf, didn't I?'" I said, "Did you tell him that you had been his good angel?" "No," said Wingfield with a laugh, "he still thinks the good influence came from above, not from a poor fellow mortal like myself."

The death took place on February 28th, in very sad and tragic circumstances, of Dr. JOHN WILLIAMSON SMITH, of Radcliffe, Lancashire. He had been found unconscious in his motor garage on the previous afternoon suffering from the effects of carbon monoxide poisoning, and in spite of the attention which he received from the hands of several of his medical colleagues, extending over a period of eight hours, he never regained consciousness. Dr. Smith, who was 45 years of age, received his medical education at Glasgow University, where he took the degree of M.B. in 1902 and M.D. in 1908. He was appointed as house-surgeon to the Bury Infirmary twenty-two years ago and afterwards house-surgeon to the Liverpool Eye and Ear Hospital. He held the latter post for about two years and then after a short period of general practice in Chapel-en-le-Frith he entered into partnership with Dr. H. W. B. Saville at Radcliffe. While at Liverpool he gained valuable experience in diseases of the eye and ear, and a few years ago opened rooms in Bury as an ophthalmologist, at the same time continuing his general practice at Radcliffe. He was honorary ophthalmic surgeon to the Bury Infirmary and oculist to the Bury education authorities. A keen and enthusiastic golfer, he was one of the most popular members of the Stand Golf Club, and at the time of his death was chairman of the handicap committee. He was a member of the British Medical Association, and in addition to acting as deputy representative for many years he was recently elected vice-chairman of the Bury Division. The funeral, which took place at Radcliffe on March 3rd, was largely attended, among those present being many brother practitioners from Radcliffe, Whitefield, and Bury.

Dr. JOHN LEWIS OWEN of Holyhead died on February 14th, aged 57, following an operation. He was a native of Ty-Croes, Anglesey, and was educated at Edinburgh, where he was demonstrator of anatomy at Surgeons' Hall; he took the diplomas of the English Conjoint Board in 1888. After acting as assistant to the late Dr. Hughes of Holyhead he commenced practice at Llanelgri, subsequently moving to Holyhead, where he practised for twenty-five years. He was a member of the Panel Committee, and at one time represented the panel practitioners on the County Insurance Committee. He was medical officer and public vaccinator for the Holyhead district, and Admiralty surgeon and agent as well as surgeon to the Post Office and the Trinity Corporation. He was a justice of the peace for the county of Anglesey and a member of the North Carnarvon and Anglesey Division of the British Medical Association.

Dr. ALFRED ROBINSON died on February 17th, aged 64, at his residence in Rotherham, after an illness of about five weeks. He was born at Merthyr Tydvil in 1860, and received his medical education at St. Bartholomew's Hospital and Durham University. He obtained the diploma of L.S.A. in 1881 and M.R.C.S. Eng. in 1882; he graduated M.B. Durh. in 1883, and proceeded M.D. in 1887. He obtained the L.S.Sc. in 1888. After filling the post of clinical assistant to the Newcastle-upon-Tyne Infirmary he commenced general practice in Rotherham in 1884, in partnership with Dr. J. Hardwicke, whom he subsequently succeeded. From 1884 to 1906 he was medical officer to the Rotherham Workhouse. In 1892 he was appointed medical officer of health for the borough, and also medical officer to the Education Committee and to the Rotherham Fever Hospital. He took a very great interest in maternity and

child welfare, and was responsible for the inauguration of an isolation hospital, small-pox hospital, a child welfare centre, and subsequently a maternity home, opened in December, 1920. He was an ex-president of the Sheffield Medico-Chirurgical Society and of the Yorkshire Branch of the Society of Medical Officers of Health. For many years he was connected with the Volunteer movement; during the war he performed home service, and retired with the rank of major in the R.A.M.C. (T.F.). Dr. Robinson contributed various articles on public health subjects to the BRITISH MEDICAL JOURNAL and other periodicals. He is survived by his widow. The funeral, on February 20th, was attended by a large number of representatives of the many interests with which Dr. Robinson was connected.

By the death of Dr. ELLISON CANSFIELD of Shipley on January 15th, the medical profession of Bradford lost one of its most devoted and conscientious members, and the Hall Lane district, where for many years he laboured unsparingly and with never-failing kindness among a large industrial population. Educated at the Bradford Grammar School and the University of Edinburgh, he took the degrees of M.B., Ch.B. with special distinction in medicine, and from there he went to the Maternity Hospital, Dublin. Entering general practice he was assistant to Dr. Pullan of Paddock, Huddersfield, and later to Dr. Robinson of Low Moor and Wyke. In 1911 he bought the practice at Windrush House, Hall Lane, Bradford, from the late Dr. Bladworth; the practice was originally carried on by the late Dr. Sam Lodge. There he worked steadily and conscientiously for many years, and built up one of the largest general practices in Bradford. His colleague, Dr. J. R. JOHN, writes:

In 1918 Dr. Cansfield joined the R.A.M.C. with a temporary commission and saw service as medical officer to the 7th battalion Lincolnshire Regiment. Within four months he was severely gassed, and after being in hospital for several months was finally invalided out of the service late in 1919. Failing to obtain adequate help under war conditions he struggled bravely to resume the heavy duties of his large practice. It was not until January, 1920, that my own demobilization permitted of my joining him as a partner, as had been provisionally arranged during our early days together in Franco. We carried on a very happy partnership—in spite of frequent breakdowns in his health—until July, 1924, when he was obliged to give up his share of the practice. Despite the devoted nursing of his wife his health gradually failed and he passed away just after his 39th birthday. A large circle of friends, patients, and fellow practitioners mourn the loss of one whose kindly nature, never-failing sympathy, and conscientious devotion to duty endeared him to all.

Dr. JOHN DOUGLAS PEARSON died on March 5th, at the age of 47. He was educated at Cheltenham College and Guy's Hospital, and obtained the diplomas M.R.C.S., L.R.C.P. in 1903. After filling the appointments of house-physician, anaesthetist, and visiting surgeon to the Chester General Infirmary, he began general practice in Cheltenham. He served in France during the war, in the R.A.M.C. For some years he was medical officer of No. 1 District of the Cheltenham Union. He leaves a widow and one daughter.

Dr. JOSEPH A. CLARKE of Dunoon died on February 10th. He was a native of Glasgow and received his education at the University there, graduating M.B., Ch.B. in 1897 and M.D. in 1900. He took the diploma in public health of the Conjoint Board in Scotland in 1911. He had practised in Dunoon for twenty-four years, having succeeded the late Dr. Gemmell. During the war he saw active service in Mesopotamia. Dr. Clarke, who was an enthusiastic Freemason, was a member of the Argyllshire Division of the British Medical Association.

Dr. PAUL MOSER, the Viennese paediatrist, and Professor E. BUMM, the Berlin gynaecologist, have recently died.

## Medical News.

THE annual meeting of the Royal Medical Benevolent Fund was held on March 17th under the presidency of Sir Thomas Barlow. The treasurer (Sir Charters Symonds) said that the invested properties amounted now to more than £100,000. The amount voted in grants during 1924 was £5,616, and the grant department showed an adverse balance of £373, but this was apparent rather than real, because a proportion of the money, although voted, had not actually been paid out. The payments to annuitants amounted to £3,277. Certain considerable legacies were falling in, but it was the rule of the fund to invest all legacies for the benefit of annuitants. Dr. Newton Pitt, the honorary secretary, said that the committee had to record an increase of £1,000 in new subscriptions, a result largely attributable to the plan of appealing by means of letters written by vice-presidents or local secretaries in different areas. The ordinary subscription revenue, however, was down, and with fewer special gifts the general result was an increase in grant income of only £50 and in total income of only £130. Altogether 490 persons had been relieved during the year—343 by grants, which were not necessarily renewable, and 147 by annuities, which were in most cases renewed from year to year as a matter of course. The war emergency fund, which had been devoted chiefly to the education of children, would be absorbed by the early part of 1926, by which time most of the beneficiaries would have reached the age of 16. The Ladies' Guild continued its valuable help in the shape of personal contact with and gifts to the grantees. The British Medical Association had greatly assisted the fund by collecting subscriptions, and during the year it had forwarded £1,110, an increase of £200 on the amount collected in the previous year. Through the instrumentality of the Association also several cases requiring assistance had been brought before the fund. He referred with great regret to the death of Dr. G. E. Haslip, a member of the committee, who was instrumental in obtaining large grants for the fund from the Medical Insurance Agency. Changes made in the personnel of the committee included the election of two representatives of the British Medical Association, Dr. R. A. Bolam and Mr. Bishop Harman. The president remarked that the committee already had the advantage of the help of another representative of the Association, Dr. C. O. Hawthorne. Mr. Basil Hall, the President of the Association, was elected a vice-president. Thanks were expressed to the editors of the *British Medical Journal* and the *Lancet* for their readiness at all times to help the fund.

A MEETING of all members of the medical profession in practice within the hospital area will be held in the library of the Royal Devon and Exeter Hospital on Thursday, March 26th, at 3 p.m., to discuss the proposed contributory scheme. The question of the wage limit to be imposed is now under consideration, and the staff desires to ascertain the views of the local profession.

THE adjourned discussion on vitamin deficiency at the Royal Society of Medicine will be reopened on Monday next, March 23rd, at 5.30 p.m. The speeches made when the discussion was opened on February 16th were reported in our issue for February 21st (p. 358) and can be read in full in the March number of the society's *Proceedings*, and those who wish for a summary can obtain galley slips on application at the society's office, 1, Wimpole Street, W.1. The general discussion of these papers will be opened by Dr. William Hunter and Dr. Robert Hutchison.

The Fellowship of Medicine announces that Mr. Ernest Clarke will lecture at No. 1, Wimpole Street, on March 30th at 5.30 p.m., on myopia, and on April 1st at the same hour, Dr. Robert Knox will give a lecture and lantern demonstration on the use of x rays in the diagnosis of lesions in the right upper quadrant of the abdomen. Members of the profession are cordially welcomed to these lectures whether members of the Fellowship or not. During the fortnight commencing April 20th an intensive course in all departments of hospital practice will be held at the Hampstead General Hospital. A course on diseases of children will also be held at the Queen's Hospital for Children on each day of the fortnight, and another on proctology at St. Mark's Hospital for Diseases of the Rectum. Early application for these courses is desirable. Copies of the syllabus of these courses may be obtained from the Secretary to the Fellowship of Medicine, No. 1, Wimpole Street, W.1.

THE annual meeting of the Society for the Study of Inebriety will be held at 11, Chandos Street, London, W.1, on Tuesday, April 21st, at 4 p.m. After the election of officers and the reception of the annual report of the council and the financial statement, Dr. Courtenay C. Weeks will open a discussion on alcohol in medical and surgical practice.

A MEETING of the Tuberculosis Society will be held at Cambridge, from April 2nd to 4th inclusive. Professor W. E. Dixon will lecture on the treatment of disease with heavy metals and bactericidal agents; Dr. Lynam on x rays in the diagnosis of pulmonary tuberculosis; Dr. R. C. Matson, of the American National Tuberculosis Association, will deal with artificial pneumothorax and the value of surgical procedures; Mr. H. Platt will discuss forms of arthritis simulating tuberculosis; and Dr. L. Cobbett will consider racial susceptibility and resistance. Sir Henry Ganvain will lecture on the present position of light treatment in surgical tuberculosis. A visit will be paid to the East Anglian Sanatoriums. A limited number of rooms will be available in Clare College, and it is hoped that cheap railway tickets will be obtainable. Further information may be obtained from the honorary secretary of the Tuberculosis Society, Dr. F. J. C. Blackmore, 138, Herbert Road, Plumstead, S.E.18.

THE North-Western Tuberculosis Society will hold a meeting at the Skin Hospital, Quay Street, Manchester, on Thursday, March 26th, at 3.30 p.m., when a demonstration (arranged by Dr. G. H. Lancashire) of tuberculous skin cases and methods of treatment, including light treatment, will be given.

THE quarterly meeting of the Society of Superintendents of Tuberculosis Institutions will be held at 122, Harley Street, on Monday, March 23rd, at 3 p.m. Dr. R. E. Woodhouse (Secretary of the National Tuberculosis Association of Canada) will give an address on tuberculosis work in Canada, and Dr. N. D. Bardswell will report the results of an experiment in settling tuberculous men on the land. Dr. A. J. Shinnie (Westminster) and Dr. Esther Carling will open a discussion on the weak points in the public treatment of tuberculosis. It is hoped that a general practitioner will speak from the standpoint of general practice.

THE third dinner meeting of the Hunterian Society of London will be held at Simpson's Restaurant, 77, Poultry, Cheapside, on Monday, March 30th, at 7.30 p.m. After dinner a discussion on the use and abuse of drugs will be opened by Professor W. E. Dixon and Dr. H. H. Dale.

At a conversazione organized by the Chelsea Polytechnic on March 13th demonstrations were given of the educational work in progress. The subjects included elementary, applied, and advanced physics; bacteriology, including the study of immunity and food and water examination; physiology, with especial reference to physical efficiency tests and biochemistry; elementary, technical, and advanced chemistry; botany; zoology; and the manufacture of pharmaceutical preparations.

THE Wellcome Historical Medical Museum will be closed for cleaning and decoration from April 1st to 30th inclusive.

A FUND has been opened for providing some addition to the building or equipment of Scarborough Hospital as a memorial to the late Dr. F. W. A. Godfrey, whose death we announced in our issue of February 21st (p. 389). It is also proposed to place a tablet in St. Martin's Church. Dr. Godfrey was connected with the Scarborough Hospital for more than thirty years, and devoted to it a very great amount of interest and labour. Contributions amounting to more than £450 have already been received or promised. Cheques, payable to the "Godfrey Memorial Fund," may be sent to the honorary treasurer, Mr. S. F. Linton, the Town Hall, Scarborough.

DR. J. WRIGHT MASON, who has retired from the posts of medical officer of health for Hull after forty-four years' service and of medical officer of the Hull and Goolo Port Sanitary Authority for thirty years, was entertained at dinner on March 9th by members of the Corporation Health Committee and of the Port Sanitary Authority, and presented with illuminated addresses by both bodies. During the evening speeches were delivered by the chairman of the Corporation Health Committee and of the Port Sanitary Authority, as well as by the Lord Mayor, eulogizing Dr. Mason's work in the interests of public health.

THE Harrogate Corporation has prepared an attractive Easter programme. Copies may be had from the General Manager, Publicity Department, Royal Baths and Wells, Harrogate.

DR. L. OMBREDANNE has been elected president of the Société française d'Orthopédie in succession to the late Professor A. Broca.

THE discussion on post-graduate study in London arranged by the Fellowship of Medicine and Post-Graduate Medical Association, which took place on Wednesday last (March 18th), will be resumed at 1, Wimpole Street, W.1, on Wednesday, April 8th, at 6 p.m.

THE announcement is made as we go to press that Sir Humphry Rolleston, Bt., K.C.B., has been appointed to be Regius Professor of Physic in the University of Cambridge in succession to the late Sir Clifford Allbutt.

## Letters, Notes, and Answers.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated. Authors desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Financial Secretary and Business Manager, 429, Strand, W.C.2, on receipt of proof.

ALL communications with reference to advertisements as well as orders for copies of the JOURNAL should be addressed to the Financial Secretary and Business Manager, 429, Strand, London, W.C.2. Attention to this request will avoid delay. Communications with reference to editorial business should be addressed to the Editor, BRITISH MEDICAL JOURNAL, 429, Strand, W.C.2.

Communications intended for the current issue should be posted so as to arrive by the first post on Monday or at latest be received not later than Tuesday morning.

The telephone number of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is GERRARD 2630 (Internal Exchange). The telegraphic addresses are:

EDITOR of the BRITISH MEDICAL JOURNAL, Aitiology Westrand, London.

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), Articulate Westrand, London.

MEDICAL SECRETARY, Medisera Westrand, London.

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Barillus, Dublin*; telephone: 4737 Dublin), and of the Scottish Office, 6, Rutland Square, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 4361 Central).

### QUERIES AND ANSWERS.

#### BEGGING LETTERS.

DR. HAROLD DOWNS (Martock, Somerset) writes: A person signing herself "Jean N. Atherton" writes to me asking for financial assistance, stating that her father was at St. Thomas's Hospital with me (which is not the case, for I am not a St. Thomas's man), but that "he failed to qualify." May I suggest that any practitioner who may feel inclined to respond should first communicate with the Charity Organization Society? This person writes from Devonshire, and asks for a loan of £3 till March 24th.

\* \* \* The address of the Charity Organization Society is Denison House, 295, Vauxhall Bridge Road, London, S.W.1.

#### ANTISCORBUTICS IN THE TROPICS.

"E. C. L." inquires as to the antiscorbutic substances which can best be used in the tropics.

\* \* \* The following standards for persons residing in a tropical country, such as West Africa, were drawn up by E. Marion Delf from careful analyses. Taking the antiscorbutic value of orange and lemon juice as 100, pineapple would be 44, pawpaw 40, vegetable marrow 33, and sweet potato 31. Fresh bananas eaten raw have a moderate value only. Tomatoes, both fresh and tinned, are also very useful. It must be noted, however, that the antiscorbutic value of all these fruits and vegetables will vary according to their freshness and method of storing. Germinating peas have a very high value; they should be allowed to simmer in a double steamer and the liquor should be used as well as the peas.

### LETTERS, NOTES, ETC.

#### A DISCLAIMER.

DR. H. W. NOTT (Little Sutton, near Birkenhead) writes: May I ask you to find room for this letter disclaiming any association whatever on my part with the lay press notices which have appeared in connexion with the thyroid and manganes treatment?

#### A NEW MOSQUITO BREEDING PLACE.

DR. J. C. RYAN, D.T.M. (late M.O., West African Medical Staff), writes: In the issue of the BRITISH MEDICAL JOURNAL of March 7th (p. 483) a note appears on "A new mosquito breeding place"—that is, palm trees. In my book entitled *Health Preservation in West Africa*, published in 1914, reference is made on page 62 to this source of danger. Therefore it is hardly correct to call it new.

#### MATERNAL MORTALITY.

"A COUNTY PRACTITIONER" writes: I cannot understand the statements now being made regarding maternal mortality. I have been in practice since 1892—twenty years in a seaside town and thirteen in a country district. During that time I have attended over 2,000 confinements without a single maternal death. I presume that my experience is not much different from that of the majority of general practitioners. Are conditions so very much worse in large towns, and is the percentage of deaths so very great, or has the whole matter been grossly exaggerated?

#### CANCER IN AFRICAN NATIVES.

DR. J. E. S. OLD, whose letter on cancer in African natives appeared in our issue of February 21st (p. 386), writes further to suggest that "cellular atavism" may be concerned in the occurrence of malignancy. He believes that help would be received from a tabulated comparison of the relative antiquity of the various races of mankind with the prevalence of malignant disease in them. The tendency to atavism may increase in inverse ratio to prepotency, which tends to produce resemblance to parents rather than to ancestors, and such composite racial blends as are found in the more civilized nations, being the least prepotent, may thus be more susceptible to malignancy if this condition contains atavistic elements. The racial tendency to reversion may be accentuated in an individual by his diet and mode of life, and become apparent. The constancy of this effect seems to him to indicate the existence of an inherited subservience to the "unconscious," and a pathological irritant, in combination with mental concentration, may awaken some latent unconscious nervous force and stimulate embryonic cells to activity. Prepotency may be a hyperdevelopment of some part of the "unconscious," and, if ill developed, may be unable to control or balance another part which is concerned with physiological activities. Dr. Old suggests that cancer hospitals might encourage a research on psycho-analytical lines, with a view to determining the presence or absence of such factors in malignant disease.

#### DAZZLING HEADLIGHTS.

DR. R. M. COURTAULD (Wakes Colne, Essex) writes: Many inventors are busily seeking an efficient motor car headlight free from dazzle, but I have not so far heard or read of any eye specialist seeking a method of making the eye dazzle-proof. Perhaps intimate knowledge of the eye would reveal the hopelessness of such a quest; *prima facie*, however, there seems here a promising path to pursue. Two methods suggest themselves to me as possibly worth a trial—namely, (1) the use by drivers of some kind of spectacles that would deprive bright light of its dazzle, while leaving illumination sufficient for safe driving; (2) the use of a myotic drug in the form of eye drops. The value of this method must depend upon the answers to three questions—namely, (a) Is there any myotic drug that can be constantly used without harm to the user? (b) Can a myotic drug render the eye dazzle-proof? (c) If the pupils of a driver's eyes were contracted by a myotic drug, could he see well enough to drive safely at night? Question (a) can be answered off-hand, doubtless, by any ophthalmologist or pharmacologist. The answers to questions (b) and (c) can easily be found by experiments.

#### INDEXES TO PERIODICALS.

THE Library Association issues a *Subject Index to Periodicals* (Issued by the Library Association: K.—Science and Technology. London: Grafton and Co., 1924.) drawn from 600 English and foreign periodicals in eight sections—namely, A, Theology and Philosophy; B—E, Historical, Political, and Economic Sciences; F, Education and Child Welfare; G, Fine Art and Archaeology; H, Music; I, Language and Literature (Part I, Classical, Oriental, and Primitive; Part II, Modern and Bibliography); K, Science and Technology. In the section now before us, for the year 1921, bearing as its date of publication December, 1924, an enclosed slip states that it includes some 6,000 entries, obtained from the examination of 290 periodicals. The price is £1 1s. net. As compared with this home production, medical literature and its allied sciences enjoy the luxury of foreign importations from the United States of the *Index Medicus* and the Cumulative Index of the *Journal of the American Medical Association*. In the course of 1922 these publications gave the references to the English and foreign literature of 1921 in an exhaustive fashion; these two publications cost libraries about 3 guineas. The *Subject Index* of the Library Association includes a few references to medical and scientific subjects, but only a very few as compared with the American publications mentioned.

#### "MEDICAMENTA RECENTIA."

THE second edition (revised and enlarged) of *Medicamenta Recentia*, published by Messrs. Allen and Haubury (37, Lombard Street, London, E.C.3), is a neat and handy little book. It contains notes, arranged alphabetically, on "Allenburys" specialties, which are so numerous as almost to form a pharmacopoeia in such barbaric ingenuity as the word "muscabane" for a fly repellent; but it must be delightful to cure one's chapped hands with chrismanhoron. The notes are followed by a therapeutic index, in which, under the name of each disease, the appropriate specialties are mentioned. There is a summary of the Dangerous Drugs Acts of 1920 and 1923; a description of the technique of injections, subcutaneous, intramuscular, intravenous, and intraspinal; a section on diet in diseases; and sundry tables of weights and measures.

#### VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 36, 37, 38, 39, 42 and 43 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 40 and 41. A short summary of vacant posts notified in the advertisement column appears in the *Supplement* at page 123.

# A Clinical Lecture ON CANCER OF THE STOMACH.

DELIVERED AT GUY'S HOSPITAL

BY

R. P. ROWLANDS, M.S., F.R.C.S.,

SURGEON TO THE HOSPITAL.

THE deaths from cancer of the stomach are rapidly increasing. In England and Wales there were 7,078 in 1919 and 8,135 in 1921. Very few of these patients ever come to the surgeon; many do not see a physician or even their general practitioner until it is too late to operate. This is partly due to the fact that gastric cancer is frequently a terminal disease in old people, for more die of this condition between the ages of 60 and 70 than in any other decade, so that the early symptoms are often overlooked or thought to be the natural result of old age. Even when an early and correct diagnosis is made in these old people a radical operation is considered to be too formidable. There is also a very prevalent opinion among the public that cancer of the stomach is necessarily fatal, and that no operation can either cure or afford much relief. The majority of patients who see the physician or surgeon come so late that either no operation can be performed or the difficulty and mortality of operation are very great; at the best, in these late cases, the prolongation of life is short, with the natural result that the public get a bad impression of the operation.

Better education of the public and of the rank and file of the medical profession, leading to earlier diagnosis and operative treatment, would bring far better results. It should be made more generally known that both the immediate and the ultimate results of early operation are good: the immediate mortality should not be more than 10 per cent., and at least one-quarter of the patients should be alive and well five years after the operation. These operative results are satisfactory for a disease which has a 100 per cent. mortality under medical treatment. At present, out of ten cases which reach the surgeon, resection is only possible in two and gastro-jejunostomy for the relief of obstruction in three, the remainder being inoperable.

Many cases of cancer of the stomach could be prevented by earlier and better treatment of chronic gastric ulcer, which is the main precursor of gastric cancer. Sberren<sup>2</sup> and Moynihan<sup>3</sup> maintain that at least 50 per cent. of cancers of the stomach arise in chronic gastric ulcers, and find direct microscopic evidence that cancer started in an ulcer in one-quarter of the specimens of cancer removed at operation. Moreover, one-tenth (Moynihan) to one-twentieth (Sherron) of supposed chronic gastric ulcers removed by them showed evidence of early cancer. Pauchet<sup>4</sup> contends that as many as 75 per cent. of cancers of the stomach arise in simple ulcers. Others deny any direct relationship between gastric ulcer and gastric cancer, but it is significant that cancer attacks just those parts of the stomach which are subject to ulcers and that the clinical history of chronic or recurring gastric ulcer is obtainable in the majority of cases of cancer of the stomach. In this connexion MacCarty's<sup>5</sup> view is important. He asks the practical question:

"Is cancer often associated with chronic gastric ulcer? From an experience of more than 1,400 gastric specimens I can state that the association is so frequent that if I had a chronic gastric ulcer I should always consider the possibility of cancer being present, and I know of no clinical or laboratory methods by which the differential clinical diagnosis can be made. From actual experience

also I know that chronic gastric ulcers with a diameter greater than 2.5 cm. are cancerous. I do not know whether the cancer or the ulcer was primary, but I do know that I would not temporize with the chronic gastric ulcer."

## SYMPTOMS.

Cancer of the stomach should be suspected in any patient, especially over 35 years of age, who suffers from obstinate dyspepsia with anorexia, wasting, anaemia, pain, vomiting (especially coffee-grounds), and achlorhydria. It should be remembered, however, that not more than 50 per cent. of early cancers of the stomach show achlorhydria, and that in over 25 per cent. free hydrochloric acid is either normal or excessive.

## DIAGNOSIS.

When cancer of the stomach is suspected it is of the greatest importance to settle the diagnosis without delay, and, with this object, every useful examination should at once be made; a fortnight is ample time for every investigation to be completed. The most reliable help is afforded by x-ray examinations by an expert. Persistent delay, defective filling, and distortion of the shadow are practically conclusive. (Fig. 1.) Carman maintains that he can make a correct diagnosis by x rays in over 96 per cent. of the cases submitted to him, but I have not found the x-ray reports so accurate as this. Further, Carman and MacCarty state that if an ulcer has a crater of over 2.5 cm. it is

FIG. 1.—Case iii; copy of radiogram of stomach taken by Dr. Lindsay Locke.

almost certain to be malignant. This is a valuable observation, but it is not entirely reliable, for I have excised several larger chronic gastric ulcers which were proved by subsequent microscopic examination to be innocent. In doubtful cases it is important to take a Wassermann reaction in order to exclude syphilis of the stomach, although this is a very rare disease. There is some danger of mistaking pernicious anaemia for cancer of the stomach, but the characteristic changes in the blood in the former condition should prevent this mistake.

Carcinoma of the body of the pancreas presents difficulties, for this condition, unlike the same disease in the head of the pancreas, does not cause jaundice. The patient has much pain, wastes rapidly, and is anaemic. Negative x-ray examinations and the absence of blood in the gastric juice or in the faeces should generally prevent this mistake. As already pointed out, it is quite impossible in many cases to distinguish between chronic ulcer and carcinoma of the stomach without microscopic section.

## INDICATIONS FOR OPERATION.

When all available methods of examination have been exhausted without settling the diagnosis an exploration of the abdomen is necessary if cancer of the stomach is to be found and treated in its hopeful stages, and this exploration should be resorted to without delay. When cancer is excluded by exploration some other disease is generally found, such as peptic ulcer or cholelithiasis, which can be best treated surgically. Negative explorations for late cases are to be avoided, whenever possible, for they carry a high mortality, chiefly from pulmonary complications. The following points indicate that an exploration is useless.

1. Bad general condition. When the general condition of the patient is so poor that he cannot be expected to stand a major operation, such as partial gastrectomy, it is a pity to submit him to an exploration, but his health may be greatly improved by careful dieting, rest, gastric lavage, and sometimes by blood transfusion before operation. In some cases a preliminary short-circuit for pyloric obstruction has the same beneficial effect, allowing a resection to be carried out at a later date (see Case ii).

2. Evidence of secondary growths. It is useless to explore a patient when hard enlarged glands are felt, especially

at the root of the neck, or when secondary growths are felt in the pelvic peritoneum on rectal or vaginal examination. Any nodules at the umbilicus, in the liver, or anywhere in the abdomen, especially with ascites, are strong contraindications to exploration.

3. Size, position, and fixation of the growth. A palpable tumour is by no means a contraindication to resection, for even a simple gastric ulcer may sometimes be felt in a thin abdomen; but the size and position of the tumour are most important, for if it is large, and particularly if it extends upwards under the left costal margin or starts in the cardiac part of the stomach, resection is not likely to be practicable. Fixation of the tumour is also very important, for if it cannot be moved from above downwards and from side to side resection is impossible. Accurate radiographic examinations give valuable help by indicating the site and extent of the growth as well as the size and capacity of the healthy part of the stomach.

As regards gastro-jejunostomy for cancer, it is generally admitted that this is of no use and should not be performed unless there is definite obstruction. In these circumstances it is a humane operation, prolonging life and making death less terrible. It does not often prolong life for more than six months, although I have known a few patients survive for two or three years in comparative comfort.

#### OPERATION.

This commences as an exploration to establish or complete the diagnosis and to determine the proper treatment. A long paramedian incision is made in the epigastrium, either to the right or to the left of the middle line, according to the position of the growth. The incision extends from the costal angle to below the umbilicus. The growth, glands, and peritoneum are carefully examined to see if resection is practicable. If the liver and the peritoneum are free of secondary growths, everything depends upon the extent and fixation of the primary growth and the presence of secondary glands about the head of the pancreas and the coeliac axis. If the primary growth extends along the lesser curvature nearly to the oesophagus partial gastrectomy will be of no avail, and, in my opinion, complete gastrectomy is hardly ever worth doing, for it carries a very high mortality and is generally followed by rapid recurrence. Those who survive it for any length of time without recurrence develop an intractable form of anaemia simulating Addison's (pernicious) anaemia. Considerable invasion of the pancreas is generally a contraindication to resection; involvement of the transverse colon or of its mesentery is not so serious, for these parts can be resected with justifiable additional risk.

#### Choice of Operation.

This depends upon the site and extent of the growth. In many cases it is necessary to remove the pylorus and from one-quarter to one-half of the stomach. After extensive resections direct union of the stomach and duodenum, after Billroth's first method, is impracticable without undue tension. Therefore the duodenum is closed and the side of the jejunum is anastomosed directly to the cardiac remnant, after Polya's method. It is better to place the loop of jejunum in front of the transverse colon, after

FIG. 2.—Polya-Balfour union.

Balfour's method,<sup>6</sup> for if recurrence takes place, as it often does about the pancreas and transverse mesocolon, obstruction of the anastomosis is not so likely when this method is used. (Fig. 2.)

When the primary growth is small Billroth's first method is an excellent one, especially if it is carried out after W. J. Mayo's plan.<sup>7</sup> Mayo mobilizes the lesser curvature, removes the whole of the gastro-hepatic omentum with its contained glands and a considerable part of the lesser curvature of the stomach, along which the growth so often

spreads. He also points out that the intramural spread rarely extends more than 3 cm. from the edge of the primary growth, and that it is not necessary to resect the stomach so widely as has so often been done, provided that the lymphatic vessels and glands are extensively removed. The wound in the stomach is sutured along the lesser curvature, so that the diameter of the opening left is not appreciably larger than that of the duodenum. With modern methods of suture the danger of leakage at the "angle" is negligible. (Fig. 3.)

FIG. 3.—Billroth No. 1, modified by W. J. Mayo. A, Part removed. B, Method of union.

When the growth is in the mid-gastric area and is not too extensive, sleeve resection, with wide removal of the lymphatic glands, is indicated, and both the immediate and ultimate results of this operation compare favourably with those of other forms of resection.

#### Operation in Two Stages.

In some feeble and old patients, and especially in those suffering from severe pyloric obstruction with vomiting and rapid wasting, it is sometimes necessary and wise to perform the operation in two stages, and, in these circumstances, a preliminary gastro-jejunostomy, well to the left of the growth, is indicated. The improvement that follows this operation is often so marked that it is difficult to persuade the patient that another operation is necessary, and it is therefore well to explain the plan of procedure before the first operation. Secondary resection of the growth is sometimes made somewhat more difficult by the previous gastro-jejunostomy, which limits the mobility of the stomach and sometimes makes it difficult to divide the latter far enough away from the growth. When this has been removed the openings in the jejunum and stomach are closed, and the anatomy of the parts is like that of Billroth's second method, which is rarely performed as a primary operation nowadays because it is unnecessarily complicated and prolonged as compared with the Polya-Balfour method.

The following three cases may serve to illustrate some of the points of this lecture. They afford striking contrasts: the first, an early case operated on with complete success, the patient being well nine and a half years after partial gastrectomy; the second, a late case with severe anaemia, calling for preliminary short-circuit and secondary resection; and the third, a very late case, beyond resection, who survived anterior gastro-jejunostomy for only a few days.

#### CASE I.

Mrs. E., aged 41, a patient of Dr. Brackenbury. She had suffered increasingly from indigestion for three years. Recently she had haematemesis and had wasted rapidly. She often vomited large quantities. Radiography revealed pyloric obstruction. I had felt a tumour of moderate size in the epigastrium a little to the right of the middle line. The patient looked ill and anaemic, was vomiting large quantities about once a day, and was unable to take more than liquids. I therefore advised operation.

Operation on August 21st, 1915 (Dr. Brackenbury present).—A long incision was made in the epigastrium to the right of the middle line. A dilated stomach, hypertrophied and oedematous, was found, and a pyloric ulcer of large size extending half-way along the lesser curvature from the pylorus, around which it formed a ring which was hard and felt like carcinoma. As the stomach was particularly movable and there were no growths in the liver, pelvic peritoneum, or glands, I decided to resect the diseased part, and this was done without delay. The gastric artery was double ligatured and divided, the left gastro-epiploic also, then the great omentum close to the transverse colon, and the right gastro-epiploic and pyloric arteries. The duodenum was crushed one inch beyond the pylorus and sealed with a running suture of linen thread and then invaginated by two purse-strings

of the same material. A loop of jejunum was brought up through the transverse mesocolon and sown to the back wall of the stomach along a selected line, a little on the cardiac side of the middle of the stomach. Thick black thread was used. The stomach was divided near the line already mentioned between two clamps so that no leakage occurred. An opening the same size as the one in the stomach was made in the jejunum and an anastomosis made as in the case of the stomach thread being used throughout. The operation was completed before the growth was removed. The operation, for the growth was useful as a tractor, and later on the attachment to the jejunum prevented retraction of the stomach during the insertion of deep sutures. The opening in the jejunum began four inches from the end of the duodenum, and by starting it here there was no tension upon the first part of the jejunum and duodenum. Only two layers of sutures were used for anastomosis. The great omentum was not removed but drawn up over the anastomosis and the stump of the duodenum. The opening in the transverse mesocolon was closed by two interrupted sutures. The operation lasted forty-five minutes and the patient was not shocked after it. She was infused during the operation, two pints being run into the arm-pits.

She was very well the next day, but vomited once or twice. On August 23rd she frequently vomited small quantities of offensive green material, and, as half a pint of sodium bicarbonate solution was given without affording any great relief, the stomach was washed out at 5 p.m. A very large quantity of bilious liquid was withdrawn and the patient felt much better. She was up on the tenth day, and walking about on the thirteenth and eating almost full diet. She rapidly gained weight and did very well. When last heard of, in December, 1924 (ten years later), she was still in excellent health.

#### CASE II.

A man, aged 64, had had gastric symptoms for years, with some melaena. When admitted to Guy's Hospital he was thin and very anaemic. He was sent up with the diagnosis of duodenal ulcer, but the diagnosis in hospital was carcinoma of the pylorus, with obstruction.

Operation on May 25th, 1922.—Dr. E. A. Scott, the anaesthetist, considered that he would not stand a long anaesthetic and operation owing to his anaemic and bad condition. I therefore performed posterior gastro-jejunostomy well away from a definite pyloric carcinoma, the size of a Tangerine orange, completely encircling the pylorus, ulcerated, hard, and at one side piercing the muscle wall of the stomach and showing peritoneal nodules. There were no secondary growths anywhere, and partial gastrectomy was thought advisable (possibly after blood transfusion) three to four weeks later. However, the patient improved so much that blood transfusion was not necessary before the second operation, which was performed on July 10th, 1922, when about half the stomach was removed. The growth proved to be a columnar-celled carcinoma. Good recovery followed, and when last heard of (January, 1925) he was in excellent health, less anaemic, and better nourished, and in regular work, cleaning cars.

#### CASE III.

Mr. G., aged 65, after suffering from severe chronic gastritis for three months, was sent by his medical attendant to see a consulting physician, who, instead of a thorough investigation, advised a three months' holiday in Devonshire. After two months the patient returned to London because he was wasting and vomiting so much. Investigation at New Lodge Clinic demonstrated defective filling of the middle of the stomach and complete absence of hydrochloric acid, with much blood in the gastric juice. There was a movable tumour in the left epigastric angle. Laparotomy was advised in the hope that partial gastrectomy would be possible, but the site and extent of the growth made me take a gloomy view of the case. The patient asked for another radiographic examination, and this was done by Dr. Lindsay Loeke, confirming the New Lodge findings. I hoped that a mid-gastric sleeve resection would be possible.

Operation on November 2nd, 1922.—A large carcinoma was found in the lower mid-gastric region. It encircled the stomach and markedly constricted it, leaving only a narrow vertical slit. The cardiac pouch was considerably dilated, and its anterior wall folded forwards and to the right in front of the stricture. There were enlarged glands on the lesser curvature, and also below the greater curvature where the growth had come through the peritoneum of the stomach and had infected the general peritoneum, there being many minute nodules all over it, especially in the pelvis. There were also larger lumps in the great omentum, but no secondary growths in the liver. The primary growth could have been removed, but the secondaries negatived resection. Complete obstruction was clearly impending, therefore an anterior gastro-jejunostomy (beginning in the jejunum ten inches down) was performed, the posterior operation being impossible owing to the position of the growth. Death occurred from bronchitis with exhaustion a week later.

## THE PREVENTION OF PUERPERAL MORBIDITY AND MORTALITY:

### AN EXPERIMENTAL STUDY IN CLINICAL OBSTETRICS.\*

BY

FRANCES IVENS, M.S.,

CLINICAL LECTURER IN OBSTETRICS AND GYNAECOLOGY, UNIVERSITY OF LIVERPOOL; HONORARY SURGEON, LIVERPOOL MATERNITY HOSPITAL; HONORARY GYNAECOLOGICAL SURGEON, LIVERPOOL STANLEY HOSPITAL.

In this paper I propose to give a short account of a series of consecutive midwifery cases which have occurred under my own general supervision in a municipal maternity home. I do so because I am of opinion that it is only by a detailed study of so-called normal labour, and of the slighter cases of puerperal morbidity, that we shall arrive at a full knowledge of the etiology of puerperal sepsis and the explanation of the terrible cases of fulminant puerperal septicaemia occurring after an apparently normal labour. When in possession of that knowledge we may hope to formulate a scheme to eliminate some of the dangers of maternity, and to decide upon a reasonable technique for the actual conduct of labour.

No one can have read the recent correspondence in the *BRITISH MEDICAL JOURNAL* without being struck by the great diversity of opinion expressed both with regard to the lack of improvement in puerperal statistics and the apportionment of blame for such a deplorable condition of affairs. Recently the published statistics of a practitioner<sup>1</sup> throw a doubt on the reliability of the statistics on which these statements are made—and I think he is probably right.

I do not think it can be denied, however, that even if puerperal mortality has really diminished there is still a vast amount of ill health among women of the poorer and middle classes which is the result of the traumata of labour, of sepsis, or of infection present in the patient before parturition. For a good many years I have been interested in this subject from a gynaecological standpoint, and it occurred to me that it would be both interesting and useful to make observations from the obstetrical side to determine how far these results were inevitable, or, if preventable, how they could be prevented. Accordingly I undertook, at the invitation of Dr. Hope, then medical officer of health for Liverpool, the supervision of the new maternity home which was started on his initiative, and which the lack of housing accommodation after the war made so necessary.

The home is small; it can take in only fourteen patients; but since its opening in 1920 1,000 women have been admitted. It was arranged that I should see, as far as possible, every case before admission, and I attended a weekly clinic at the home when women desiring admission presented themselves for examination.

After notes of the case had been taken and the urine tested, I examined each patient, measured the pelvis, and made an internal examination to determine the diagonal conjugate. A specimen of any abnormal discharge was sent to the city bacteriologist for report. Cases of active syphilis or gonorrhoea were referred to a special institution, as the size of the home did not permit of satisfactory isolation. Cases of albuminuria, cardiac disease, or hyperemesis were admitted for ante-natal care, and abnormal cases were kept under regular observation so that the obstetrical treatment required might be carried out at the proper time. The home was well equipped for simple cases, but any requiring Caesarean section were sent to the Stanley or Maternity Hospital, either before labour or when it had started. Each case was as far as possible admitted a day or two before the anticipated date of delivery.

On admission, after a preliminary abdominal examination has been made by the matron or sister, the regulation bath is given and a dose of castor oil and an enema. Before any internal examination is made the vulva is shaved and washed very thoroughly with lysol solution

\* Read at a meeting of the London Association of the Medical Women's Federation. A brief abstract was published in the *British Medical Journal* of March 7th (p. 450).

(1 in 320) over a douche-pau. In emergency cases tincture of iodine is also used.

During labour all those concerned with the case, including the pupil midwives (who are trained nurses), wear sterilized overalls and boiled gloves. Sterile towels are used, and great care is taken to avoid infection from the anus, especially in multigravidae where the perineum has been ruptured or where prolapsed or inflamed haemorrhoids are present.

The matron or sister conducts all normal cases, with the assistance of the pupil midwives, and reports any abnormality that has been discovered during ante-natal examination or that is discovered on admission. Should the case be not proceeding normally they are asked to send for assistance in good time, and where there is slight contraction of the outlet or uterine inertia and the second stage is unduly prolonged, forceps are not withheld if required. If perineal rupture takes place it is repaired at the earliest possible moment, silkworm gut being used. Catgut is avoided as being too favourable a culture medium.

During the puerperium the vulva is swabbed with lysol solution over a douche-pan (each patient has one for her own use) every four hours during the day, and a large sterile pad applied to absorb all lochial discharge. If the perineum is ruptured the wound is kept specially dry, and is touched once a day with tincture of iodine.

To help involution and to avoid a collection of lochia in the posterior fornix, the patient is encouraged to lie on her side part of every day, and to sleep in an exaggerated Sims's position, which is not uncomfortable. Anteversion of the uterus is thus encouraged. In cases of ruptured perineum metronitration is performed on the hands and knees, so that the wound is not soiled and catheterization is avoided.

The following is an analysis of the 1,000 patients admitted since the home was opened:

Pre-maternity cases	...	...	...	...	206
Maternity cases—					
Primiparae	...	...	...	390	679
Multiparae	...	...	...	289	
Post-natal cases	...	...	...	...	115

I propose to discuss in this paper the maternity cases only.

#### MATERNAL MORTALITY AND MORBIDITY.

There has been no maternal mortality and no maternal morbidity (under Central Midwives Board rule) among the cases delivered in the home. I shall deal in detail later with the few cases which have shown any slight deviation from the normal, and their causation as far as it could be traced.

#### Contracted Pelvis.

Contracted pelvis was present in 130 cases: in 92 of the 390 primiparae (23 per cent.) and in 38 of the 289 multiparae (13 per cent.).

**Primiparae.**—The rather high percentage of contracted pelvis in primigravidae is probably due to the fact that a proportion of the cases are referred from outside clinics, doctors, and midwives for special observation and care. Of the 92 cases in primigravidae—

1. Natural delivery took place in 36, with 35 living children. The dead child was a pelvic presentation; the mother had slight contraction of the pelvis.
2. Forceps were employed in 17, with 16 living children. The child born dead weighed 9 lb. 8 oz.; presentation right occipito-posterior; slight contraction. The size of the child was not discovered sufficiently early to permit of Caesarean section.
3. There was induction of premature labour in 17, with 16 living children. The mother of the dead child suffered from morbus cordis, which was followed by puerperal insanity.
4. Caesarean section was performed in 18, with 18 living children.

**Multiparae.**—Of the 38 cases of contracted pelvis in multigravidae—

1. Natural delivery took place in 16, with 16 living children.
2. Forceps were employed in 3, with 3 living children.
3. Premature labour was induced in 16, with 16 living children.
4. Caesarean section was performed in 3, with 3 living children.

Of the total 679 maternity cases natural delivery took place in 601 (88 per cent.).

Table showing Proportion of Contracted Pelvis in 679 Maternity Cases.

	Primiparae.	Multiparae.	Total Cases.
Normal measurements ...	298	251	549
Contracted pelvis ...	92 (23 %)	38 (13 %)	130
Total ...	390	289	679

#### Complications.

**Post-partum Haemorrhage.**—Three severe and two slight cases occurred; all survived. The treatment employed was massage of the uterus and pituitrin and ergotin injections. Occasionally a hot intravaginal douche was used.

**Adherent Placenta.**—Manual removal of the placenta was required seven times, but in no case followed by pyrexia.

**Perineal tears** of varying degree occurred in 78 cases of normal labour and 20 forceps cases. Primary union was almost invariable, and there was no pyrexia. Small tears were stitched.

**Fibromyomata.**—In two cases labour was complicated by the presence of fibromyomata, but progressed normally. In one case the tumours were enucleated three weeks later and were then found to be undergoing necrobiosis.

**Twin Births.**—Eight pairs of twins occurred, of which four were in primiparae. All the children but two lived—one a pelvic presentation in a primigravida, and the other a vertex with tight short cord. Locked twins occurred once. Considerable delay took place in the second stage. Under anaesthesia one twin was found to be presenting by the vertex with its neck stretched across the neck of the other, which lay transversely. The transverse twin was dislodged and pushed up, and the first delivered by forceps. The other then presented by the vertex and was also delivered by forceps. Both were born alive and survived; one weighed 5 lb. 12 oz., and the other 4 lb. 14 oz.

**Occipito-posterior Position.**—Eighteen cases of unreduced occipito-posterior position occurred; 9 were delivered by natural forces, 3 by forceps after manual rotation, and 6 by forceps. In one, an elderly primigravida with rigid cervix and slightly contracted pelvis, Caesarean section was performed. All the children were born alive, except in the one instance of large child and contracted pelvis already mentioned.

**Placenta Praevia.**—Eight cases occurred—2 central, 6 marginal. Two cases of central placenta praevia were delivered by Caesarean section in the Stanley Hospital. Both children were premature; one, though weighing only 3 lb. 11 oz., survived; the other died after a few hours. One multigravida with vertex presentation was treated by rupture of the membranes and full doses of pituitrin. The child was stillborn. The remainder were delivered by natural forces of living children.

**Prolapse of cord** occurred twice. In the first case the cord was prolapsed and feebly pulsating on admission. Reposition was effected, but the child was stillborn. The second instance occurred with a pelvic presentation.

**Pelvic Presentations.**—There were 23 cases. In 14 the child was born alive; in 5 the child was premature; in one primigravida with slight contraction the child died during delivery; in one primigravida with large child the infant was stillborn; one (a monstrosity with included twin) died five days after birth; in one primigravida the first twin was stillborn. Caesarean section was performed for two primigravidae with contracted pelvis. Both children were born alive, but one had congenital deformity of both arms (absence of the radius).

**Face Presentation.**—This occurred twice. One case was born alive by natural forces. One (an anencephalic monster) was stillborn.

**Eclampsia.**—Although a considerable number of cases of albuminuria were treated, no case developed eclampsia. One case of eclampsia was sent in as an emergency and had had no ante-natal treatment. She was admitted in labour, comatose, with swelling of legs, 7 grams of albumin per litre, and several fits had occurred. One fit took place after admission. Delivery was effected naturally, but the

child was stillborn. The first child had died of convulsions at 8 months. The mother made a good recovery, and when seen three years later the urine was normal.

#### *Induction of Premature Labour.*

Three methods have been employed—namely, quinine and castor oil (25), gum-elastic bougies (6), and toy rubber balloons (17). The first method was found to be unreliable, although it occasionally was successful where the child was post-mature. Bougies were discarded partly on account of their slow and uncertain action, partly on account of the risk of carrying vaginal organisms into the upper segment, of rupturing the membranes, or of causing retroplacental haemorrhage. (During bougie induction in one case slight haemorrhage occurred. Labour did not come on, and the patient was delivered three weeks later by Caesarean section. A large retroplacental haematoma was present.) The balloon method was brought to my notice by Professor Lowry of Belfast. A general anaesthetic is employed. The vagina is douched with 1 in 2,000 mercuric bichloride lotion, and the uninflated balloon introduced through the cervix, which is fixed by means of modified Collins's lung forceps; 16 oz. of sterile water are introduced with a syringe through tubing tied on a glass tube in the neck of the balloon.

The indication for an induction was usually some disproportion between pelvis and child. There were 17 cases, with 17 living children (one—a first twin in a primigravida—being stillborn owing to some delay with the after-coming head). The average gestation period was thirty-eight weeks, and the average weight of the children 6 lb. 13 oz.

Two cases required forceps—one a right occipito-posterior presentation with long second stage, and the other (a second twin) for uterine inertia. In the third case, induced because of post-mature child and slight contraction, the induction was delayed because of the history of septicæmia in the first confinement and risk of latent sepsis. The patient was removed to hospital, and high forceps were used. The child weighed 9 lb. 8 oz. and was delivered alive. Streptococci were isolated from the urine of the mother (Case v).

In two cases Caesarean section was required—the first a pelvic presentation in a primigravida with diagonal conjugate of 4½ inches; the second a multigravida of 42, who had had four forceps deliveries and one previous induction with a living child of 7 lb. 4 oz.

#### *Forceps Delivery.*

Delivery by forceps was effected in 30 cases (4.4 per cent.): in 20 for contracted pelvis (of which 8 were posterior positions); in 3 for cardiac disease; twice for twins, and the remainder for uterine inertia. Low forceps were employed in all but three cases of mid-forceps and the one case of high forceps already mentioned. Contraction of the outlet was noted in 8 cases. The children were all born alive, except the large child in posterior position already referred to. In one cardiac case the premature infant died four hours after delivery.

#### *Caesarean Section.*

Caesarean section was performed in 29 cases: for contracted pelvis in 21; for central placenta prævia in 2; for pre-eclamptic conditions in 3; for rigid cervix in 2; and for grave cardiac disease in 1. These cases were removed, either before or during labour, to the Stanley or Maternity Hospital, and operated upon by myself in 25 cases, in 3 cases by Miss Nicholson, M.S., and in 1 case by Mrs. Dobbin Crawford. The mothers all survived, and the children were born alive.

Three neo-natal deaths took place: (1) premature (placenta prævia); (2) premature (pre-eclamptic) on fifth day; (3) spina bifida on fifth day. In 24 cases the puerperium was afebrile and healing was by primary union. In 5 the puerperium was febrile.

#### *Infant Mortality.*

Thirty-nine infants were stillborn or died in the first ten days; 22 of these were premature.

Ante-natal death occurred in 12—prematurity 8, syphilis 1, anencephalic monster 1, spina bifida 1, cause unknown 1.

Intra-natal death occurred in 18; 8 were due to prematurity, and the following conditions were responsible for one each—placenta prævia, impacted shoulders, left occipito-posterior presentation with contracted pelvis and large child, achondroplasia, breech presentation with large child, toxæmia of pregnancy, breech presentation with contracted pelvis, twin (tight cord), breech presentation (primigravida), spina bifida.

Neo-natal death occurred in 9—prematurity 6, congenital heart 1, monster (included twin) 1, pemphigus 1.

#### *Infant Morbidity.*

There were 7 cases of pemphigus—one (premature, ?syphilitic) died; 3 cases of gonorrhoeal ophthalmia—all recovered; 1 case of congenital blindness; and 8 cases of inflammation of the eyes.

#### *MORBIDITY.*

Although no cases in the home itself have reached the Central Midwives Board standard of morbidity, some slight deviations from the normal have occurred. In 5 out of the 29 Caesarean sections, and in one case of high forceps with latent streptococcal infection, there was morbidity (Central Midwives Board).

#### *Latent Gonorrhoea.*

CASE I.—A primigravida had been under treatment for gonorrhoea and syphilis in a venereal diseases clinic. Before admission to the maternity home discharge had ceased for some weeks. A normal confinement took place. On the fifth day a rigor occurred; temperature 102.8°, pulse 120. The patient was anesthetized and the uterus explored. A little membrane was removed; 20 c.cm. of antigonococcal serum was given subcutaneously, together with 10 c.cm. of antistreptococcal serum as a prophylactic against a possible secondary infection. Gonococci only were found in the uterine discharge. Temperature and pulse dropped to normal, and the patient made a good recovery.

CASE II.—A primigravida, single, a dwarf. There had been a vaginal discharge during pregnancy, but no gonococci found. Caesarean section was performed (S.H.). The temperature reached 101° for the first few days and discharge was profuse. Gonorrhoea suspected.

CASE III.—A primigravida with a definite history of gonorrhoea and syphilis. Normal pelvis. In labour four days, with ruptured membranes twenty-four hours. The head was well in the pelvis, but the cervix did not dilate. Caesarean section was performed. The liquor amnii was discoloured and there was difficulty in removing the child, which was tightly gripped by the uterus. The membranes and placenta were yellow and unhealthy-looking. Drainage was employed. At the operation 20 c.cm. of antigonococcal serum and 10 c.cm. of antistreptococcal serum were given subcutaneously in saline. The wound was not healthy, but there was no rise of temperature. Gonococci had been found. In this case there is little doubt that the gonorrhoeal infection caused the rigid cervix.

CASE IV.—Primigravida. Husband seafaring man. Normal ante-natal history except for prolapsed hæmorrhoids. Normal confinement. Rigor on the ninth day, associated with pain in the right side. Some yellow discharge noted. Intracellular Gram-negative cocci present in pus. Mercurial vaginal douche. No further trouble.

#### *Latent Streptococcal Infection.*

CASE V.—A 2-gravida, aged 33. First child stillborn; forceps delivery, followed by septicaemia. She was an unhealthy-looking stout woman with some oedema of the ankles. Diagonal conjugate 4½ in. There had been an occasional trace of albumin during pregnancy. Perineum torn to anus. Induction was delayed on account of a history of septicaemia. When fourteen days overdue balloon induction was employed, as Caesarean section was contra-indicated and the child large. The head remained high and pains went off. She was transferred to the Maternity Hospital. Pulse 132; hæmorrhagic vomiting. A living child of 9 lb. 8 oz. was delivered with Tarnier's axis-traction forceps. Some post-partum hæmorrhage was controlled by pituitrin. Offensive lochia and raised temperature followed delivery. Streptococci were isolated from the urine. She was given 20 c.cm. of antistreptococcal serum, and made a good recovery.

In this case it is probable that streptococci were present in the bladder during pregnancy and accounted for the albuminuria. No vaginal discharge had been noted.

CASE VI.—A primigravida, aged 25. In this case albuminuria occurred at intervals during pregnancy, and some vaginal discharge was present. A specimen taken before delivery showed short chains of streptococci. Owing to uterine inertia, low forceps were employed for delivery, followed by mercurial douche. There was an afebrile puerperium.

CASE VII.—A 2-gravida, aged 31, with a previous history of prolonged labour with a large child, septicaemia, and white leg. She had had three attacks of appendicitis eight years before, but no operation. There was a trace of albumin in the urine during pregnancy. Labour was normal. On the seventh day she had

shivering and headache; temperature 101.6°, pulse 120. Streptococci in lochial discharge. She was given an intrauterine mercurial douche. The puerperium was normal.

#### Latent Infection with *B. coli*.

CASE VIII.—A primigravida with a rickety flat pelvis. Diagonal conjugate  $4\frac{1}{2}$  in. *Coli* bacilluria during pregnancy. The head did not fix. Caesarean section was performed and a child weighing 7 lb. delivered. The membranes were yellow and unhealthy. Some temperature during the puerperium with pyuria and unhealthy wound. *B. coli* isolated from urine and cervical discharge.

CASE IX.—A married woman, aged 28; one previous abortion. Diagonal conjugate  $4\frac{1}{2}$  in. Occasional albuminuria during pregnancy. In labour twenty-four hours with ruptured membranes. Head above brim; liquor amnii offensive; cervix rigid. Temperature 103°, pulse 104. Caesarean section performed; placenta adherent; drainage. Infant (7 lb. 10 oz.) blue from asphyxia. On the following day the infant had blebs on the fingers and vaginal discharge. Febrile puerperium; rigor on the fifth day. *B. coli* septicaemia. Anticoli serum, 20 c.cm., given subcutaneously in saline. The patient recovered.

In this case, unfortunately, the cause of the albuminuria during pregnancy was not investigated. It is possible that a latent bacilluria was present.

#### Coli Infection.

CASE X.—A primigravida, aged 25. Diagonal conjugate 4 in. Head entering pelvis. Membranes ruptured forty-eight hours. Liquor amnii discoloured. Cervix one-third dilated. It was decided to do Caesarean section. A child weighing 6 $\frac{1}{2}$  lb. was delivered; its head was much moulded. The patient was cyanosed and vomited haemorrhagic fluid in large quantities during the operation. The placenta and membranes were yellowish-green and adherent. The following day the infant's eyes were reddened and vulvitis was present. The mother's condition was serious. She had acute bronchitis with cyanosis, frothy sputum, and incontinence of urine and faeces. The pulse was very rapid and out of proportion to the temperature. Coliform organisms were present in the vaginal discharge. Anticoli serum, 10 c.cm., was given subcutaneously and she made a good recovery.

In this case it is probable that a *B. coli* infection from the rectum supervened during the prolonged labour with ruptured membranes. In one other case there was some morbidity, and the value of a few days' preliminary care in the home was demonstrated.

CASE XI.—A primigravida had been examined at the clinic and slight general contraction found, but it was thought that she would probably deliver herself. She came up in labour a few days before the expected date, the head above the brim. The membranes ruptured, but the head did not fix. Temperature 99.8°, pulse 100. The cervix was half dilated. Caesarean section was performed, and a living child, weighing 8 lb., was removed. The placenta was separated with difficulty. Post-operative bronchitis with rapid pulse and slight temperature occurred. Streptococci were found in the lochial discharge. The patient, however, made a good recovery.

In connexion with cases admitted in labour, the statistics of v. Nuben<sup>2</sup> on the association of premature rupture of the membranes and diseases of the puerperium with marital relations shortly before labour need consideration.

#### CONCLUSIONS.

From such a small number of cases it is unwise to draw any definite conclusions. I am of opinion, however:

1. That latent or pre-existing infection, streptococcal, gonorrhoeal, or coliform, is responsible for a considerable percentage of cases of puerperal sepsis. That the organism may not infrequently be isolated by bacteriological examination of the urine during pregnancy, especially in cases of streptococcal or coliform infection. That intermittent albuminuria during pregnancy is an indication for a bacteriological examination of the urine, even in the absence of urinary symptoms. That with latent infection uterine inertia is more likely to occur, especially when associated with premature rupture of the membranes. That bacteriological facilities for the examination of discharges during pregnancy, if utilized, will enable suitable precautions to be taken and an appropriate serum to be obtained.

2. That for the prevention of puerperal sepsis cases should be removed from unsuitable surroundings, especially when difficulty is anticipated, and that ample accommodation should be arranged so that patients may be admitted a day or two before labour is anticipated.

3. That a rigidly aseptic technique is as important as for a surgical operation. The patient should be carefully prepared and the vulva shaved before any vaginal examination is made during or immediately before labour. That well trained midwives can deliver a very high percentage

of maternity cases if satisfactory ante-natal examination and care have been given by the patient's doctor, and if skilled medical help, and, if necessary, institutional treatment, can be obtained when required. Co-operation between midwives and doctors should be aimed at, and maternity homes should be worked in conjunction with hospitals where expert ante-natal and obstetrical treatment can be obtained.

4. That with a reliable technique in good surroundings operative measures need not cause puerperal sepsis.

5. That in view of the need for study of the origin and character of the infecting organism in cases of fulminating puerperal fever, such cases should be placed at the earliest possible moment under the care of an obstetrical specialist and bacteriologist with facilities for research on the special type of organism.

In conclusion, I wish to thank Dr. Hope and Dr. Mussen for the extensive facilities they have afforded me; Miss Nicholson, M.S., who has assisted me indefatigably throughout; Professor Beattie and Dr. Ashcroft for their bacteriological reports; Dr. Capon and Mrs. Barton Hall for investigating most of the cases of stillbirth; and the matron, Miss Nicholson (Central Midwives Board), and Sister McCaughey (Central Midwives Board) for their invaluable and enthusiastic co-operation.

## FIBROCHONDROMA OF THE CAUDA EQUINA.

BY

F. J. A. GREAVES, O.B.E., F.R.C.S.Eng.,  
HONORARY SURGEON, DERBYSHIRE ROYAL INFIRMARY;

AND

F. GRAHAM LESCHER, M.C., M.A., M.D.CANTAB.,  
HONORARY ASSISTANT PHYSICIAN, DERBYSHIRE ROYAL INFIRMARY.

Tumours of the caudal region of the spinal cord are by no means common in hospitals for nervous diseases; still less often are they encountered in general hospitals. On searching the clinical records of the Derbyshire Royal Infirmary we have been unable to find any other example of this condition.

Spinal cord surgery dates back some thirty-six years, when Horsley successfully removed a tumour from the dorsal region of the cord. It was in 1902 that the first lesion of the cauda equina was correctly diagnosed and successfully operated on.

In 1896 Dufour collected 21 cases of tumour of the spinal cord. Of these cases only one had been operated on, and that successfully. In 1908 Spiller<sup>2</sup> published an account of 9 cases, 3 of which had been operated on, and in one the tumour had been removed. There were 7 deaths, including all 3 who had been operated on.

Several other authors have published accounts of cases attended with greater success, including one of a cauda equina tumour.<sup>3</sup> This was removed, and the patient made a complete recovery.

The literature on the subject of the spinal cord tumours was analysed by Steinke<sup>4</sup> in 1918; he collected accounts of 330 cases, among which were thirty tumours of the cauda equina. Of the latter, 5 were cured, 9 were improved, and 14 died early.

In the recent reports<sup>5</sup> of the Mayo Clinic there is an account of 112 laminectomies for supposed tumour of the spinal cord in the years 1910-22. In 85 cases a tumour was found, but in 3 cases only was the lesion in the region of the cauda equina, and of these 2 were due to meningomyelitis and 1 to a tumour.

The following account is of a patient with typical symptoms, and physical signs, of a lesion of the cauda equina.

G. C., aged 42, a miner, was sent by his doctor in February, 1924, to the Derbyshire Royal Infirmary. He gave the following history. In 1920 he began to suffer from a dull ache in the lower lumbar region, and shooting pains down the back of the right

thigh. These improved during the next year, when he underwent treatment at a spa, but they recurred in 1922 and gradually became worse. In 1923 he noticed that his right leg was becoming weaker, and that there was some numbness about the perineum. In December of that year he experienced a sudden pain in the suprapubic region, and inability to micturate. After relief by catheterization there was incontinence of urine. He also stated that he was very constipated, and had not proper control over his bowel.

He was a . . . . . had not lost weight. He had difficulty . . . . . rked weakness in the right leg. There was . . . . . wasting, and loss of tone in the flexor muscles of the thigh. All . . . . . could be carried out, but they were weaker than those of the left side. There was no limitation of movement on bending the back, but there was some local tenderness over the lower part of the vertebral column. There was pain on pressure over the right sciatic nerve, which was increased on flexing the thigh on the trunk, and extending the leg on the thigh.

FIG. 1.—Area of loss of epiradic and protopathic sensation; also of superficial pain and temperature sense. The second, third, fourth, and fifth sacral roots are affected on the right side; on the left the fourth and fifth.

The most significant physical signs were those of disturbance in sensation. There was definite impairment and loss of epiradic and protopathic sensation, with superficial pain and temperature sense, which extended from the top of the back of the right leg up the thigh in a narrow strip, and over part of the right buttock, and to a lesser extent over the left one in a saddle-shape manner. Loss of sensation extended over the perineum, scrotum, and penis. Deep pain sense and joint sense remained natural.

The distribution of pain, sensory disturbance, and the loss of muscular power pointed to the involvement of nerve roots, the particular ones involved being the second, third, fourth, and fifth, and to a lesser extent the first sacral, on the right side, and the fourth and fifth sacral on the left. Testicular sensation had remained, since the normal nerve supply is from the lumbar plexus. The mucous membrane of the urethra and the lower part of the rectum and anus was insensitive, as the man could feel neither urine nor faeces when they were passed. On inserting the catheter it could not be felt.

On rectal examination the examining finger was not felt. The sphincter ani had lost tone, and on withdrawing the finger the orifice remained patulous.

The abdominal and cremasteric reflexes were active; the knee-jerks, though diminished, especially on the right side, could be elicited. Both ankle-jerks were absent, and the plantar response was flexor.

The patient suffered from retention and overflow of urine. The urine, on admission, was alkaline, and contained some pus cells and blood, and a growth of *Bacillus coli*. After regular catheterization, and with urotropin and acid sodium phosphate taken internally, the urine became sterile, and remained so during the time he was in hospital, with the exception of a slight attack of cystitis for a few days after operation.

An x-ray examination of the lower part of the vertebral column and sacrum showed no evidence of disease or injury of the bones. Lumbar puncture was performed, the needle being inserted in the space between the spines of the third and fourth lumbar vertebrae. The cerebro-spinal fluid was not under increased pressure, was colourless, and contained no cells or excess of albumin. The Wassermann reaction in this fluid and in the blood was negative.

There was no evidence of any disease of the abdomen or pelvis, or of any other part of the body.

The diagnosis of a lesion of the cauda equina in this case was made on the long history of pain in the back and down the right thigh, involvement of definite nerve roots, muscular weakness, loss of control of the sphincters, and the absence of any other nerve signs. These symptoms distinguished it from peripheral neuritis, or a more generalized disease of the nervous system. Disease of the vertebral column, abdomen, or pelvis could be excluded.

As regards the nature of the lesion, it might be due to a chronic inflammatory state or a growth, but it could not, in view of the history, be caused by a vascular or acute inflammatory condition. The commonest chronic inflammatory condition is a syphilitic meningomyelitis, a gumma, or even a tuberculoma. Against the two former was the negative Wassermann reaction in the blood and cerebro-spinal fluid, and the absence from the latter of any lymphocytes. Were the lesion a meningomyelitis we should have expected the physical signs in the legs to be symmetrical instead of being more advanced on the right side. It was more likely, then, to be a growth of a non-malignant type, for were the growth a sarcoma we should have expected a shorter history, more advanced signs, and a greater involvement of the cord.

The next point to be determined was the level of the upper part of the tumour. It was likely to be below the third lumbar intervertebral space, since the cerebro-spinal fluid from this space showed no evidence of compression of the cord elements. The fact that the fifth lumbar root on either side was not involved made us think that the upper limit of the growth was situated below the point at which this root left the cauda equina—that is, about the level of the upper part of the sacrum. But since lesions of the spinal cord tend to be located too low, we considered that the upper border was situated about the level of the fifth lumbar vertebra.

As regards the treatment, if nothing was done the patient's condition would gradually get worse, paraplegia would develop, he would become bedridden, and would die of cystitis and infection of the kidneys, or septic absorption from bedsores. This case, however, seemed a very hopeful one from the operative point of view. We had enough facts to justify us in thinking that we had diagnosed the possible nature and the level of the lesion; but in planning the operation it had to be borne in mind that lesions of the spinal cord tend to be situated higher up than the symptoms and physical signs indicate. Owing to the uncertainty, in any given case, of the obliquity of the course of the sacral nerves, and remembering the massive backward projection of the transverse processes, it was determined to remove the laminae of the fourth and fifth lumbar and the first sacral vertebrae, and further bone if found necessary.

#### Operation.

The operation took place on March 1st, 1924. An incision of the skin was made over the spinous processes of the fourth and fifth lumbar and the first sacral vertebrae, the cut edges being protected with tetra towels. The muscle layers were elevated from their bony attachments by means of a sharp periosteal elevator. The bleeding was controlled quite satisfactorily with pads of gauze, wrung out in hot saline solution, held in place by the retractors; no vessels were tied at this stage. The bony arches of the fourth and fifth lumbar and first sacral vertebrae were then removed, and a very good exposure of the thecal sheath was thus obtained. At the level of the upper border of the fifth lumbar vertebra a well marked narrowing of the theca was seen; above this narrowing pulsation under the dura could be seen and felt; below it there was no pulsation. On palpating the dura a definite hard nodule could be felt under the membrane lying to the right of the middle line. The dura was incised in the mid-dorsal line for about 1½ inches. No cerebro-spinal fluid escaped until the obstruction was divided, when immediately cerebro-spinal fluid, perfectly clear in appearance, started to flow. It did not appear to be under any great pressure. Fine catgut stitches were inserted on each side of the cut edge of the dura, to act as retractors. The cauda equina was now well in view, and a mass was seen lying to its right side, pressing the cauda equina to the left. The tumour was shaped like a leech, having its head downwards, and a long granular-looking tail extending upwards just out of sight. On carefully lifting up the tumour, which was quite hard, the head and body were found to be lying free in the subdural space, but the tail was attached. Extending the thecal incision slightly, the attachment was found to be to the inner side of the dura, and not to any of the nerve roots. With very slight traction the whole tumour came away. The dural incision was closed with the finest catgut. Pulsation throughout the exposed length of the theca was restored. The wound was then closed in layers, a few bleeding points being picked up with forceps, and ligatured. No drainage of the wound was employed. Except for firm bandaging over large pads of wool, no splinting was adopted. The patient was laid on a flat mattress, and sandbags were placed on each side of the pelvis to keep him still, whilst the foot of the bed was raised on blocks.

FIG. 2.—Photograph of the tumour after removal.

#### After-history.

The patient did not suffer to any extent from shock, although the operation lasted over two hours. The further surgical history of the case was uneventful; the wound healed by first intention, and there was no leakage of cerebro-spinal fluid through it. There were no post-operative symptoms attributable to loss of cerebro-spinal fluid during the operation. Previous operators have called attention to the serious consequences which may ensue if much fluid is drained away. For the first few days after his operation the pain down the right thigh was worse, being complicated with severe and painful flexor spasms. The right leg was also weaker. By the end of a week these symptoms began to improve, the pain slowly left him, and the power of movement increased in his leg. At the end

of a month he was out of bed and walking about. The anaesthesia was slower in clearing up, but improvement also occurred with regard to this, and has continued slowly up to the present. The slowest improvement of all was that of control of the bladder and rectum. Catheterization was still necessary, and he developed a mild attack of cystitis, which was, however, quickly overcome by the usual remedies. About the end of the third week he experienced slight feeling when the catheter was passed, and appreciated the passage of flatus. It was not till April 24th that he managed to pass urine spontaneously, this being helped by the pressure of his hands on the lower abdomen. This he did every hour, and so managed to keep the bladder empty, but if he went longer than an hour involuntary dribbling occurred.

#### Pathology of Tumour.

The pathology of this tumour is very interesting, and is unique according to the literature on the subject to which we have had access.

Dr. Hugh Barber, pathologist to the hospital, who cut a section of the growth, reported that it was a fibrochondroma. Professor Dudgeon also cut and examined several sections for us, and he says:

"This is a very interesting specimen. It is largely a chondroma with areas of necrosis, and at the periphery some calcification. There is a fibrous covering in places, and the fibrous tissue runs

bladder will empty itself. He is just conscious of the flow of urine. There is practically no dribbling between these times, so that he has been able to discard the absorbent bag which he formerly had to wear. He has educated his lower bowel to act once in the twenty-four hours at a certain time, but he is almost insensitive to the passage of the motion. The sphincter has regained most of its tone.

The prognosis in this case is good. Since the growth is non-malignant there is no likelihood of recurrence, which, of course, is not the case with the sarcomata. In Warrington's case, for instance, part of a sarcoma of the cauda equina was removed, with improvement of symptoms, but after three months recurrence took place, and the patient died. The same, though to a lesser degree, may happen to the endotheliomata.

Finally, although there has been pressure on the cauda

FIG. 4.

strands of fibrous tissue which run into the tumour.

into the cartilaginous tumour. The fibrous tissue shows extensive old haemorrhage with tissue reaction, and marked phagocytosis of the blood pigment by the tissue cells. This would suggest that the tumour had become twisted. There are no other elements present. The cartilage cells are of the large type, such as we see in articular cartilage.

Having regard to the fact that at the operation we found that the tumour was attached only by such a narrow tail, we think Professor Dudgeon's surmise as to the twist is correct.

The nature of this tumour must be very rare. Steinhe,<sup>4</sup> in his analysis of the pathology of 330 tumours of the spinal cord, reports 26 cases of fibroma, 6 of chondroma, 2 of chondrosarcoma, but none of fibrochondroma. The commonest tumours are sarcoma (112 cases) and endothelioma (28 cases). The 3 cases of caudal tumours of which Percy Sargent<sup>5</sup> has given an account all proved to be sarcomatous.

The after-history of this case has been one of great though slow improvement. At the present time (February, 1925) his right leg is almost as strong as his left. He can walk several miles each day without undue fatigue, and is doing light work. He complains of no pain. The area of hypaesthesia is less, but it has been stationary for the last two or three months. The part involved now is over a small portion of the right buttock and perineum. Sensation in the urethra and anal canal is still impaired, especially in the latter. He can retain his urine for about three hours, then with an effort, helped by suprapubic pressure, the

equina for some considerable time in our case, we hope that we have interfered before degeneration has occurred, and that restoration of function may be complete.

## IRRADIATION OF MILK AND THE HEALING OF RICKETS.

BY

S. J. COWELL, M.B., M.R.C.P.

(From the Royal Infirmary, Sheffield.)

The two processes of growth and bone calcification in young animals are intimately connected, as has been repeatedly stressed by E. Mellanby.<sup>1</sup> An adequate supply of fat-soluble vitamin in the food is essential if the animals are to grow normally and to have their bones normally calcified. But it has been shown recently that if a minimum amount of fat-soluble vitamin is present in the animals' food or tissues, exposure of the animals to ultra-violet rays will, up to a certain point, make good the deficiency of vitamin, thus promoting both good growth and good bone calcifica-

tion in animals fed on diets which would otherwise be inadequate for these purposes.

Observations on the effect of ultra-violet rays on children were published by Hulschinsky<sup>2</sup> in 1919. He was concerned with the calcification effect, and showed that active rickets could be healed by exposure of the children to

the rays of a mercury vapour lamp. In 1922 Hume,<sup>3</sup> mainly concerned with the growth-stimulating effect of the rays, showed that young rats fed on a diet deficient in fat-soluble vitamin would grow if they were exposed to ultra-violet light. This same observation was made independently by Goldblatt and Soames<sup>4</sup> and published also in 1922. In 1923 Hume and Smith<sup>5</sup> found that good growth in young rats could be obtained, in spite of deprivation of fat-soluble vitamin in the food, if they were kept in glass jars which were periodically exposed to ultra-violet rays. They found subsequently<sup>6</sup> that this good growth, and with it good bone calcification, occurred only when sawdust was present in the jars while they were being irradiated, the "activated" sawdust having apparently a similar growth-promoting and bone-calcifying effect to that of fat-soluble vitamin. In the meantime Steenbock and Black<sup>7</sup> had shown that if a rat's food ration, deficient in fat-soluble vitamin, were exposed to ultra-violet rays it became "activated" and produced as good growth and calcification of bone as if the animal itself had been irradiated.

In the light of these experiments it seemed important to determine whether any similar effects could be demon-

Breakfast: Bread 2 oz., margarine 1 oz., milk 8 oz., orange juice 1/2 oz.

Lunch: Milk 4 oz.

Dinner: Meat 2 oz., potatoes 3 oz., milk pudding 2 oz., orange juice 1/2 oz.

Tea: Bread 1 1/2 oz., margarine 1/2 oz., milk 4 oz., marmite 1 drachm.

Supper: Bread 1 oz., margarine 1 drachm, milk 6 oz.

(b)

FIG. 1.—Radiograms of wrist of a girl, aged 1 year and 5 months, taken (a) on admission, (b) after one month's dieting, the milk not being irradiated. Active rickets with poor calcification of the ends of the bones is revealed in both radiograms, only a slight improvement having taken place during the month. The child had only very slight deformity of the limbs, and was remarkably fit and lively during the whole period.

The three children thus received each one pint of milk in the twenty-four hours, and this was virtually the only source of antirachitic vitamin in their diet. As the test was carried out during the winter months the amount of vitamin was presumably not great. The milk destined for two of the children was exposed to the rays of a mercury vapour lamp of the Hanat type before it was given to them, while the third child received untreated milk. The irradiation was carried out twice a day by exposing the milk in a wide shallow dish for twenty minutes at a distance of 3 feet from the lamp. At the end of four weeks the children's wrists were again x-rayed. It will be seen from the illustrations that in the case of the child that received untreated milk there was during the month only a very slight increase in the amount of calcification at the lower ends of the radius and ulna, while in the case of the

two children that had received milk that had been exposed to ultra-violet rays dense calcification had taken place, much in excess of what one would expect to have occurred in this short time as the result of giving this particular diet.

This quite definite and remarkable "activating" effect of ultra-violet rays on foodstuffs is obviously well worth

(c)

(d)

FIG. 2.—Radiograms of a girl, aged 1 year and 5 months, taken (c) on admission, (d) after one month of the same diet as in the first case, except that the milk was irradiated. Dense calcification is seen to have occurred during the month's treatment.

(e)

FIG. 3.—Radiograms of a girl, aged 2 1/2 years, taken (e) on admission, (f) after one month's dieting, irradiated milk being given. In this case also great increase in calcification occurred during the month.

strated in the case of children. Accordingly the following test was made of the efficacy of radiating children's food as regards the promotion of bone calcification. Three young children with active rickets, as determined by radiographic examination of their wrists, were admitted to hospital. They were given the following diet, which was not in itself calculated to promote particularly rapid calcification of their bones.

following up, and opens up new possibilities in the treatment of infantile disorders.

This work was assisted by a grant from the Medical Research Council and carried out in Professor E. Mellanby's wards at the Sheffield Royal Infirmary. I wish to express my gratitude to him for permission to publish the cases and for his valuable criticism and help.

A GENERAL SURVEY OF RADIOTHERAPY IN  
MALIGNANT DISEASE.\*

BY

S. GILBERT SCOTT, M.R.C.S., L.R.C.P.,  
RADIOLOGIST TO THE LONDON HOSPITAL.

This is the fifth annual discussion on radiotherapy since the year when, as President, I suggested that this subject should become a hardy annual until it had been thoroughly thrashed out.

The subject is being discussed in all countries by men who look at it from various points of view. Radiologists are swayed this way and that by new theories and methods which are advocated with persistent regularity. The subject is undoubtedly very complex, and we are apt to lose sight of the wood because of the trees. I propose to outline the wood a little more clearly.

To do this, let us call a halt and take a brief survey of the present position. This survey should embrace the disease, the therapeutic agent, and the patient.

## THE DISEASE.

To ensure keeping to the right road, it is essential that we should have a clear conception of the disease we are attempting to attack. I grant we know little as yet as to the cause of cancer, but we do know the usual course it takes, and we must plan our attack accordingly. We cannot expect to attain our object immediately. The high-voltage technique raised our hopes; it was thought that a short cut had been found to our object—a cure for cancer—but sufficient time has now elapsed since its introduction for us to realize that, while a definite advance has been made, we have yet a long way to go before reaching our goal—if ever it is reached. It might be said that prevention would be a short cut to the cure of cancer.

Some try to persuade us that malignant disease is a local disease. This is true within narrow limits; it certainly commences as a local lesion—the primary growth; but radiologists must not lay their plan of attack on this assumption alone. The surgeon very rarely sees early cases and radiologists practically never. We must, in any case, play for safety. The primary growth is but an indication that the patient has malignant disease, and does not by any means give us a correct idea as to its extent. A very small lesion, often undetected even *post mortem*, may give rise to extensive secondary deposits. I have in mind an operation for retrofixation disclosing a very small nodule of one ovary. This was removed. A very small island of malignant cells was detected microscopically, yet in three weeks the abdomen was full of large secondary deposits.

To ensure our plan of attack being developed on sound lines, it must be based on the assumption that malignant disease is a generalized disease and not a local lesion.

Ingenious and elaborate schemes have been devised to ensure the primary growth receiving its lethal dose. Satisfaction may be expressed on its reduction or disappearance, but the patient dies very shortly from secondary deposits. The gland areas are occasionally irradiated, but this is not enough; there are no means of being certain where stray pathological cells have already settled. I maintain that if the primary growth can be destroyed by radiation, metastases will be equally susceptible, possibly even to a much smaller dose, for they are usually less bulky. At present we concentrate on the primary growth; we must go further and endeavour to control the offspring which may be settling down comfortably elsewhere. I do not say that this control will ever be achieved, but it is the ideal we should certainly try to attain. It will, at the same time, ensure our working along the right lines. Surgeons are not content with removing the primary growth; why should radiologists be?

## THE THERAPEUTIC AGENT.

I must confine my remarks to x rays. Some radiologists advocate the high, others the low, voltage technique. A further distinction would be homogeneous and heterogeneous

radiation. *Homogeneous* radiation (high voltage) means, briefly, the use of a bundle of rays of one particular penetration. *Heterogeneous* (low voltage), on the other hand, means the use of a large number of rays of all penetrations, filtering out those rays likely to injure the skin. Either of these forms of radiation may be used on the intensive principle, but results do not necessarily depend on this factor. These two forms of radiation cannot be divorced from each other. It would be a tragedy if radiologists were to become divided into two separate schools—the high and the low voltage.

It is important that we should not discard heterogeneous radiation. It is of the greatest value, as those of us who have been utilizing it for many years know. It has its limitations, but the newer method should be an addition, and not a substitute. The reports from various countries make one realize that even under the best conditions the results of homogeneous radiation are, on the whole, disappointing; they may improve as the technique is developed. Let us not scrap our machine guns because a long-range gun has been invented. To be fully equipped we require elasticity in our apparatus, so that each case can be treated on its merits, for in some the heterogeneous radiation will be more suitable than the homogeneous, and vice versa. Every radiotherapeutic department, therefore, to be complete, should be so equipped that radiation at all voltages is available, in order that any desired condition of radiation may be repeated at will. Cannot the physicists investigate the low-voltage technique with the same care and enthusiasm they have bestowed on the high-voltage? The former has by no means been fully worked out.

Professor Wirtz, in his last report on results of radiation of carcinoma of the uterus—the most suitable type of case for high voltage—concludes with the following interesting statement: "In spite of the best technique with favourable initial conditions and good general state of the patient, the results are from time to time inexplicable, so that one is compelled to believe that for the cure of carcinoma with x rays certain unknown biological factors play a certain part." I should like to substitute "an important" for "a certain."

The question as to how radiation affects morbid cells is far too complex to be discussed in detail here. There are, however, several important factors that may be briefly mentioned.

Radiation does not destroy or remove unwanted cells like the cautery or knife. Profound changes are set up which allow them to be absorbed and replaced by healthy cells. This is important to remember, for it means that malignant cells can be made to undergo a change, resulting in their replacement by normal tissues, without necrosis taking place—in short, a metamorphosis without cellular death.

It is clear, therefore, that tissue reaction plays an important part. If, for some unknown reason, this reaction fails, no amount of radiation will succeed in destroying the pathological cells. It is thus evident that there is a local indirect effect of radiation; carried further, is it not possible to create it on a larger scale generally, calling up all Nature's forces to assist in the cure? In other words, may it not be possible by radiating a large area to set free in the body some antitoxin or enzyme that will assist in the desired destruction? The work of many physicists supports this theory. I have myself on several occasions seen lympho-sarcomatous glands in unirradiated parts disappear after large areas have been irradiated. In one case this was manifested in half an hour! Is radiation sickness evidence of the liberation of something of the nature of an antitoxin? I have said enough to indicate a line for future research.

To sum up, let us have all forms of radiation at our command, and apply them with judgement and circumspection, for each case is a study in itself. Uniform dosage for all the various forms of carcinoma or all varieties of sarcoma cannot be entertained. Lastly, our results may be dependent, not only on the direct effect of radiation, but on some as yet unknown indirect phenomena. Experimental data are rapidly accumulating, indicating that the occurrence and nature of immunity to cancer is a field of study from which we may expect much in the near future.

\* A paper read to the Section of Electro-Therapeutics of the Royal Society of Medicine, March 20th, 1925.

## THE PATIENT.

It is not fit that we medical men should be accused of treating the human body as if it were merely so many cubic centimetres of material. We are all conscious of the so-called "personal element"—that tantalizing something—present, but yet not measurable. A patient for radiation should not only be thoroughly investigated physically, but his age, state of health, and so on, must be taken into consideration before deciding whether radiation will achieve anything beneficial to him.

Radiation being decided upon, the next point is to map out clearly the lines of treatment to be adopted. These may be palliative or curative. Of the patients seen by radiologists, in the majority palliation only is all that can be hoped for. This side of radiotherapy is of great value, but is being lost sight of in our efforts to cure. It is quite impossible, in certain cases, to attempt to eradicate the disease, and the chances are that if we do not discriminate the last condition of the patient will be worse than the first. The therapeutic goal varies, and each case must become a study in itself. I make it a rule to put down the objects I hope to achieve by radiation, and my plan of treatment is arranged accordingly.

*Radiation Sickness or Malaise.*—Radiation sickness is the bughbear of radiation. We have to inquire what its cause is, and whether it should be regarded as evidence of over-dosage. The results are often disastrous to the patient, being sufficient to turn the scale against him. This puzzling phenomenon may manifest itself in several ways. Actual vomiting may occur as the patient is undergoing treatment, or sudden nausea with or without vomiting may be experienced from one to seventy-two hours after. As hospital patients describe it, "I come all over alike—sudden." Intense headache may be complained of without gastric symptoms. With the high-voltage line of treatment vomiting may become uncontrollable. In its treatment various drugs have been advocated from time to time, but so far I have found nothing to control it. At present I do not consider that we are justified in subjecting a patient to the risk of severe radiation sickness unless we can promise him something substantial in return.

*Carcinoma Mammæ.*

The majority of cases that find their way to the radiological department of the London Hospital, and probably at most of the hospitals in England, come under this heading. Over two thousand have been treated at the London Hospital in the last fourteen years. For this reason I have always endeavoured to improve the technique for this large class of case. Whether inoperable, recurrent, or requiring prophylactic treatment, malignant disease of the breast illustrates very clearly the problem we have to solve in radiation of cancer.

*Prophylactic Methods of Radiation.*—After the primary growth has been removed, not by radiation, but by the surgeon, the radiologist is called in. His interest now is not distracted by the presence of a tumour; he has to devise a technique that has a reasonable chance of destroying cells at unknown depths and positions. This is a complex problem, but it must be faced. The surgeon can, in a number of cases, remove the primary growth and glands without our help, but he is not satisfied with the results because he does not necessarily prevent metastases or recurrence. This, then, is where the radiologist can help. Even if it were possible to destroy with certainty every primary growth by radiation or any other method, I personally should not be satisfied. Metastases kill the patient just as rapidly. We must control these in addition to the original cancer.

I consider heterogeneous radiation to be of greater therapeutic value than homogeneous in the prophylactic treatment of breast cancer, for these reasons: It gives radiation absorption at various depths; a large radiation field can be utilized with minimum general disturbance. I readily grant that further development is required on these lines. I have already reached the limit of the toleration of the patient under these conditions.

There are four chief objections to the high-voltage method in this class of case:

1. The radiation field is necessarily much too limited.
2. There is no indication as to the depth at which the dose should be delivered.
3. Damage to the lung tissue is comparatively frequent.
4. General disturbance—such as sickness and blood changes—place too great a strain on the patient.

The response of many a hopeless case is often remarkable if the heterogeneous radiation is carefully carried out.

*Radiation of the Whole Trunk.*—I maintain that whatever form of radiation is used in cases of breast carcinoma, it is useless and against common sense to limit it to local areas. Radiation should, if possible, include the whole trunk. It benefits the patient but little to check the metastases in a localized area while they go ahead elsewhere. As there is also evidence for the theory that in many cases the patient's tissues—we do not know which—have the ability of producing some beneficial reaction, the larger the field of radiation the better.

As a preliminary effort towards achieving the conditions I consider necessary in the treatment of these cases, I introduced the dual open method at the London Hospital some three years ago. Briefly stated, it consists in placing a tube at the back and front of the patient, both running at the same time, the radiation field including practically the whole trunk. The results show, without doubt; that this arrangement has greatly increased our range of control, benefit being now obtained in cases previously out of our reach, such as secondary deposits in the spine. This is all to the good, but much research is necessary before any further advance can be expected. To my mind this is certainly a logical method of radiation, where stray pathological cells may be at unknown depths and positions. It must be realized that attempts to substitute physics for biology and medicine can only hinder sound progress in radiotherapy.

## EMPHYEMA OF THE LEFT SPHENOIDAL SINUS WITH OPTIC NEURITIS AND SUBSEQUENT POST-PAPILLITIC ATROPHY

BY

R. E. WRIGHT, M.D., MAJOR I.M.S.,  
SUPERINTENDENT, GOVERNMENT OPHTHALMIC HOSPITAL, MADRAS.

WITHOUT actual exploration of the sphenoidal sinuses it is impossible to exclude disease of these cells as the responsible factor in certain cases of optic nerve disease. A very considerable amount of work has been published on this subject, but in spite of careful observations we are still without reliable guides, either signs or symptoms, to lead us to a definite diagnosis in cases of optic neuritis due to sphenoidal sinusitis. The case here recorded is an example of one in which there was little to indicate the true nature of the case; it also emphasizes the value of a routine examination of the sinuses on both sides.

A Hindu woman, aged 40, married, was brought to see me on April 17th, 1923, complaining of loss of vision in the right eye and headache of two months' duration. The vision of the right eye was fingers at 3 metres; left eye vision 6/9 bar one letter with plus 1.0. D.S. = 6/5. The headache was frontal for the most part, but with definite occipital pain, chiefly on the right side. The pupil reactions and tension were normal on either side. The right disc was somewhat swollen and oedematous on the nasal side, pallid and steamy in appearance; the arteries were narrowed and sheathed (subsiding papillitis). The left disc showed quiet neuritis, a red swollen disc with definite venous engorgement. The eye grounds were otherwise normal. There was no history of syphilis or evidence of it clinically; the Wassermann test was negative. There were no symptoms pointing to cerebral disease except headache. The reflexes were normal, as also the urine and blood. There was slight prorrhoea, but x-ray photographs did not show anything definite either as regards teeth or sinuses. The right field could not be taken; the left was examined with Lister's perimeter in uniform daylight illumination (intense north light over each shoulder). 5 mm. at 33 cm. for white and

colours, and was well within normal limits. Scotometric tests with Bjerrum's screen and Elliot's scotometer revealed nothing abnormal, either as regards scotomata, relative or otherwise, with white or colours, or enlargement of the blind spot.

The patient was temporarily put on mercury and large doses of potassium iodide. As a routine I would have examined the nasal sinuses on obtaining such negative results, but unfortunately I left for Europe on April 24th, 1923, and she went home and continued to take mercury and potassium iodide. On January 3rd, 1924, the Wassermann reaction was observed to be negative. On July 3rd I again had an opportunity of examining her. Vision was then: right, fingers at 2 inches; left, 6/5 partly with correction. There was definite post-papillitic atrophy of the right disc with narrowing of vessels. The left disc was oedematous and swollen to 5 D. (suggestion of papilloedema). Examination of blood, urine, nervous system, and skull by x rays gave negative results. There were no symptoms of pressure. The fields and vision of the left eye remained the same. I was unable, owing to indisposition, to undertake the exploration of the sphenoidal cells at this time. She went to her home and was not seen again till August 13th, when she was admitted to hospital. The result of ophthalmoscopic examination on this date is thus recorded: "The right disc is definitely atrophic. The arteries are quite narrow, the veins about normal; there are slight pigmentary disturbances at the disc edge; a post-papillitic atrophy. The left disc is red and slightly swollen, but much more like a neuritis than a papilloedema. There are no changes in the fundus otherwise." Perimetric and scotometric examinations gave the same results as before; the urine and blood examinations were again negative. The blood pressure was 125 mm. Hg.

On August 16th I made a full examination of the nose on both sides under local anaesthesia. The right side was normal. The sphenoidal sinus ostium when opened up disclosed a pearly-grey healthy membrane lining a small sinus. The left side of the nose appeared normal as regards frontal and ethmoidal regions, but the ostium of the sphenoidal sinus was blocked, and, on pushing the sias probe through, pus escaped under slight pressure along the probe. The anterior wall of the sinus was partially removed, revealing a thickened and red lining. The sinus was dried out and packed with bismuth gauze and the patient sent for x-ray examination.

This method of demonstrating the relation of one sphenoidal sinus to its fellow by packing one sinus with bismuth gauze and then taking a stereoscopic x-ray photograph is useful, and aids considerably in reading the x-ray plates aright. The left sinus was much more extensive than the right, and partially enveloped it. Presumably it was of the variety to which both nerves were related, the right nerve being more vulnerable (either by virtue of a larger course in the sinus or a thinner bony canal) than the left. Such relations of the optic nerves are described and exemplified by Onodi. The patient was discharged a few days later. In November, 1924, the vision was: right, fingers at 2 metres; left, 6/6 with correction. The left field showed a slight general contraction under the same conditions as above. On ophthalmoscopic examination the left disc was almost normal in appearance. The right disc showed a post-papillitic atrophy with threadlike sheathed arteries. My note says: "The fundus immediately surrounding the disc shows a greyish granular appearance, but I would consider the disc within normal limits did I not recognize the patient."

A most interesting point, in connexion with the case is the nature of the field of the left eye. Careful tests on several occasions elicited nothing. This is in contrast with many recorded cases, in which a relative central or paracentral scotoma is a prominent feature. The fact that the right nerve suffered most in a left sinus affection must be comparatively uncommon. The left nerve, although affected in greater or lesser degree for over eighteen months, retained its function (although subsequent subsidence of its inflammatory condition brought as a sequel a slight cicatricial damage associated with a trivial fall in vision and a contraction of the fields). It is noteworthy that in an ordinary x-ray examination pus in the sphenoidal sinus is liable to be overlooked. Evidently, in doubtful cases of papillitis, it is very desirable to explore the sphenoidal sinuses on both sides; one must not be content with finding a normal sinus on the side of the most affected eye. This is in many cases such a simple procedure that there is no justification for omitting it.

Dr. Muthayya, medical officer in charge of the refraction department, very kindly collected and analysed the notes of this case.

## EMBRYOMA IN THE OMENTUM CAUSING SYMPTOMS SUGGESTIVE OF URETERAL CALCULUS.

BY

A. E. WEBB-JOHNSON, C.B.E., D.S.O., M.B.,

F.R.C.S.,

SURGEON TO THE MIDDLESEX HOSPITAL.

The following case is of interest, both from the point of view of pathology and of diagnosis.

A woman, aged 40, was sent to see me at the Middlesex Hospital, with a provisional diagnosis of renal calculus. Her symptoms were certainly suggestive of this condition being present. She complained of attacks of pain in the left loin coming on suddenly and radiating towards the inguinal region. She also complained of some irritability of the bladder with painful and frequent micturition, which persisted for some time after the attacks of lumbar pain. The urine contained pus, but no blood cells. The organism present was the *Dacillus coli communis*.

An x-ray examination showed the kidney region to be free from any sign of calculus, but in the pelvis was a shadow of irregular shape, about the size of a large plum-stone. Cystoscopic examination showed the bladder and the ureteral orifices to

FIG. 1.—Radiogram taken in an oblique direction with an opaque catheter in the ureter.

be normal, with the exception of some slight congestion of the bladder mucous membrane. Although the shadow in the pelvis was not in the least like that of a urinary calculus, I thought it better to make sure that it was not in the urinary tract. I therefore passed an opaque ureteral catheter, and had an x-ray photograph taken. The examination showed that the shadow of the catheter was superimposed on that in the pelvis, but another radiogram taken in an oblique direction showed that the shadow was separated by a small interval from the course of the ureter (Fig. 1). As the irregular shape of the shadow suggested that it might be caused by a calcareous deposit in an ovary, I asked Mr. Comyns Berkeley to co-operate with me in an exploratory laparotomy. Mr. Berkeley opened the abdomen, but found that both ovaries were normal; I then extracted a small, hard, irregular-shaped tumour, freely movable across the pelvis, but attached above to the lower edge of the omentum and below by a thin fold of peritoneum to the posterior wall of the bladder. The connexion with the bladder and the free mobility of this hard mass probably accounted for the patient's symptoms of pain and frequency of micturition, which were so suggestive of some disorder of the urinary tract.

On section the tumour was found to be of mixed formation, part of it being cystic and part of it hard, bony, and calcified. The cystic part contained a mass of hair and sebaceous matter. The tumour was evidently a small embryoma.

In Sir John Bland-Sutton's book *Tumours, Innocent and Malignant*, we read:

"Many cases have been reported in which cysts containing pilose skin, and occasionally teeth, have been found on the omentum and the serous covering of the intestine. In some

instances these cysts are due to the rupture of an ovarian dermoid, and some of the cells scattered about the abdominal cavity have engrafted themselves on the peritoneum, and formed independent cysts. Quite apart from cysts arising in this way, teratoid cysts do arise independently between the layers of the mesentery, the omentum, and the folds of peritoneum connected with the caecum, colon, and rectum, as well as the omentum. Most of the reported cases occurred in children and adolescents,

FIG. 2.—The teratoma cut across (two-thirds size), showing the hard part (opaque to the x rays) and the cystic part containing grease and hair.

especially females. As a rule the cyst contents are grease and hair, but some are more complex and contain bone, cartilage, muscular and nerve tissue.

"It is impossible to recognize the nature of such cysts clinically. They seem to remain latent for a variable period, and then with dramatic suddenness cause acute abdominal pain simulating peritonitis, or intestinal obstruction. Some never cause trouble and are found accidentally at a *post-mortem* examination."

These intra-abdominal embryomata, though quite rare, are well known. They are probably connected in some way with the development of the genital glands, and the position of this one in the immediate neighbourhood of the left ovary suggests that it was developed from a primordial cell isolated from the developing ovary.

The special interest of the present case lay in the anatomical connexions of the tumour, which produced a train of symptoms suggestive of disease of the urinary tract.

#### DIAPHRAGMATIC HERNIA AFTER BULLET WOUND OF CHEST.

The following case is interesting, not only from a pathological standpoint, but is worthy of comment as emphasizing the possibility of late sequelae in war pensioners who have received gunshot wounds of the chest.

W. J., aged 35, received a gunshot wound in the chest a fortnight before the armistice. The bullet (which was not removed) entered the back of the left side of the chest, approximately 4 in. below the inferior angle of the left scapula and 2½ in. from the middle line.

I was called to see him on the evening of March 2nd, 1924—approximately five and a half years after he had been wounded. He had been taken ill that afternoon with retching and recurrent attacks of vomiting, associated with colicky pain all over the abdomen. The condition did not subside, but continued till the following day, when it was obvious that he was suffering from acute intestinal obstruction.

He was admitted to Ulverston Cottage Hospital, and, approximately twenty-four hours after the onset of the illness, I explored the abdomen by an incision below the umbilicus, splitting the right rectus. The caecum, distended to the calibre of an adult fist, presented itself at the wound. The distended gut was traced along the colon, as far as the region of the splenic flexure, where it appeared to vanish. The descending colon was collapsed. With the arm in the abdominal cavity up to the elbow I was able to feel an acute kink in the region of the splenic flexure. The apex of the kink appeared to be firmly adherent to the diaphragm by strong cicatricial tissue, and the bowel to be enveloped by

tissue of a similar nature. As the patient's general condition was poor (he had had two or three faecal vomits just before the operation) I closed the abdomen and performed a temporary caecostomy.

Four weeks later the abdomen was reopened by a long paramedian incision, extending from the left costal margin to below the level of the umbilicus. The small intestine was packed off, and the area of the splenic flexure investigated. I was able to view the lesion. There was a fairly large diaphragmatic hernia, the sac containing the splenic flexure and the terminal part of the transverse colon. I was able to introduce two fingers into the sac externally to the gut. It was impossible to dislodge the contents of the hernia, as the gut was firmly adherent to the sac wall by thick bands of cicatricial tissue. At the fundus of the sac the scar tissue was most pronounced, and this may have been due to an encapsulated bullet, but I could not be certain of this.

To have attempted to reduce the hernia by breaking down adhesions would almost certainly have ruptured the diaphragm, and possibly also the pleura. Accordingly ileo-sigmoidostomy was performed and the abdomen closed.

Three weeks later the caecostomy opening was closed. Some leakage occurred about the seventh day after operation and the faecal fistula recurred. It was considered advisable to give the patient a period of rest to recuperate after the three operations before attempting to reclose the opening in the gut. Accordingly he was discharged from hospital, having been fitted with a suitable controlling belt.

Three months later he was admitted to the Ministry of Pensions Hospital, Liverpool, where the fistula was successfully closed. He is now fit and well, his bowels moving regularly *per vias naturales*.

There is nothing in the man's previous history of interest other than to state that for two years prior to onset of the illness he was particularly subject to flatulence. He had never been troubled with constipation. The case, therefore, was one of acute intestinal obstruction due to an irreducible diaphragmatic hernia of traumatic origin.

I must acknowledge the services of Mr. French of Birkenhead, who performed the fourth stage of the operation, and in supplying an account of it, without which the notes of the case would have been incomplete.

Ulverston.

#### PER-URETHRAL OPERATIONS FOR PROSTATIC OBSTRUCTION.

MR. KENNETH WALKER, in his excellent article on per-urethral operations for prostatic obstruction (*BRITISH MEDICAL JOURNAL*, January 31st, p. 201), has brought into prominence work that is, I believe, carried out by only a few surgeons in this country. Perhaps the conclusions I have come to in work which has been done largely in the Surgical Unit here during the last four years may not come amiss. The method employed has been fulguration of the prostate carried out by a diathermy electrode introduced through the cysto-urethroscope.

In the malignant prostate, where so much had been hoped for, the results were poor. In the adenomatous prostate, where enlargement of the lateral lobes could be detected by rectal examination or seen through the cystoscope, any improvement was only temporary, and not greater than that which followed the introduction of a full-sized metal bougie—a method of treatment in vogue many years ago. In addition, there can be no question that in this type of case such treatment is dangerous. When, on the other hand, the middle lobe was alone involved and not much enlarged, much improvement followed fulguration; this has so far been permanent, and the residual urine has completely disappeared.

In the prostatic bar, which was secondary to atrophy of the prostate, and in the small fibrous prostate, excellent results were obtained. But in the chronic inflammatory enlargement with residual urine, which did not react to massage and dilatation, the improvement was not so immediate or so marked, though it gradually became greater.

Fulguration is not so severe an operation as prostatectomy; the mortality is much less and the convalescence much shorter. But it should not be regarded as an alternative to prostatectomy except where the middle lobe alone is enlarged. It should be carried out only in those cases where prostatectomy is unsuitable, not on account of the general condition, but owing to the state of the prostate gland itself.

Cardiff.

T. F. HAMMOND.

TREATMENT OF GENERAL PARALYSIS BY  
MALARIA.

THE purpose of this note is to call attention to a new method for the preservation of malaria parasites—namely, on ice *in vitro*—first used, I believe, in this country in our laboratory in November, 1924. The technique of the new method, which comes from the clinic of Pöetzel of Prague, is as follows:

On withdrawal the parasite-containing blood is defibrinated by shaking it up with glass beads in a flask or test tube under sterile conditions; the fluid, containing corpuscles and parasites, is transferred to another sterile test tube, and this is kept in the ice-chest, or, if for immediate dispatch, packed surrounded by ice in a thermos flask.

By this means simple tertian parasites have been kept alive and capable of infecting for varying periods up to and beyond sixty-five hours, and thus the difficulty of successfully inoculating due to distance and time in transit has been overcome.

Mosquito-borne malaria need not and should not now be used, for, being more liable to relapse and not so completely under quinine control as inoculated malaria, it is a danger to the community.

It may be taken that sixty-six hours is by no means the limit, for we have found the parasite stain well after seven days in the ice-chest. Successful inoculation by this means has been obtained in London, Birmingham, and Liverpool, with blood sent from here.

## AN OBSCURE CEREBRAL CONDITION.

THE following account of a somewhat unusual case appears to be of sufficient interest to merit publication. The onset of the illness was acute, and included pyrexia, which lasted for a fortnight, severe gastritis, and constipation for three weeks, and violent eye movements which continued for a month.

On the evening of August 30th, 1924, I was called to see a boy, aged 14, who had not felt very well on the previous day, but had bathed twice in spite of this; after the second bath he felt sick and giddy and went to bed. When I saw him he was pale, sighed frequently, said he felt very giddy and sick, and looked as if he might vomit at any moment. The pulse rate was 80 and regular, the temperature 100° F.; the bowels had not acted for two days, and the tongue was very furred. He kept his eyes tightly shut, and the eyelids were twitching. I did not examine the eyes, as he said it made him feel sick to open them. He was a very intelligent, quiet boy, not at all drowsy, and he had no headache. Nothing abnormal was found in the chest or abdomen, but I did not examine the nervous system. The next day he vomited several times, and the tongue was very furred; the bowels had not acted. The temperature was 101° and the pulse 92. On September 1st the temperature ranged from 98.8° to 100.4°; he still complained of extreme giddiness, which made him sick, especially if he opened his eyes or moved his head. He could not move his head from the pillow without jerking it violently, but there was no twitching or jerking of the limbs, and the head remained stationary unless he moved it voluntarily. He could only open his eyes with an effort, and it was noticed that they were in violent motion, in no regular direction; the eyes would go round and round three or four times, then from side to side in the most irregular manner, and with great rapidity, so as I could make out both eyes moved together. There was no lateral deviation; on asking him to look to one side he was able to fix the finger for a moment, the violent movements would then This sequence occurred whatever the position of the finger again. had no diplopia. His most comfortable position was lying on his back with his head slightly inclined to the left on one thin pillow. He afterwards described his sensations at this period as if the bed first "pitched" very rapidly, then "rolled," then rotated so that he felt he was going to be flung out at an angle of 45 degrees, quite aware that the bed was really stationary. He attributed the sickness to the feeling of movement, being normally a bad traveller, and hardly able to look at the sea without feeling sick. He had no headache.

Dr. Basil Armstrong saw him in consultation that day and examined him very thoroughly. The ears appeared normal, and there was no history or evidence of past otorrhoea; tuning-fork tests showed aural conduction to be greater than bone conduction, and no diminution of hearing was detected. There was no facial weakness, but the tongue protruded very slightly to the left. No stiffness of neck was present. Examination of the arms showed that the muscular power was good, the jerks were normal, the co-ordination normal, and there was no dysidiadokokinesis. The abdominal and cremasteric reflexes were normal. The knee- and ankle-jerks

were slightly increased on both sides, and the plantar responses were flexor; Kernig's sign was absent. The sensation was carefully tested and found normal everywhere. Lumbar puncture was not performed. The urine was acid and highly coloured; albumin, sugar, and acetone were absent.

For the next week the temperature ranged from 98.2° to 99.4°, and the pulse remained slow, always under 80 and generally between 60 and 70. The eyes still continued their rapid movements of wide amplitude, but the patient gradually became able to fix objects for a longer time. The gastric symptoms then became more prominent; there was complete anorexia, furred tongue, very obstinate constipation, and vomiting of very tenacious mucus, which was alkaline in reaction. A differential blood count showed nothing abnormal. After September 11th the temperature remained normal, and the eyes gradually steadied, but the rate and amplitude of movement did not alter. The gastric symptoms and tongue cleared quite quickly between September 16th and 18th. On September 22nd the eyes were steady, but attempts to sit up brought back at once the rotatory movements as badly as ever, and made him feel sick and giddy. He had one or two restless nights about this time, but they soon got better, and never became a prominent symptom.

During the last week in September I began to prop him up with pillows, and after a few days he was able to sit up; he then went out in a bath chair, and no untoward symptoms appeared. In the first week in October he was able to walk, and he then returned to his home near London. On October 15th I heard from his parents that he was quite well, but that they had decided to keep him from school till after Christmas. Retinoscopy was impossible during the early part of the illness, but at the end of September I was able to see the fundus without difficulty; there was nothing abnormal, except that the veins seemed a little engorged.

The treatment was symptomatic and cannot be said to have had any effect on the disease; at first I gave chloral, bromide, and sodium bicarbonate; then sodium bicarbonate before and hydrochloric acid after food; in the third week he had hexamine, and when convalescence was established iron, quinine, and arsenic. In a letter dated March 6th, 1925, his mother tells me that he has had no return of the giddiness; he eats well and sleeps well; he has returned to school and is making good progress. In fact "he is quite his old self again." He has not suffered from headaches.

Westgate-on-Sea.

FREWEN MOOR, M.C., M.D.

## ANEURYSM OF THE SPLENIC ARTERY.

THE case published by Mr. D. C. L. Fitzwilliams (BRITISH MEDICAL JOURNAL, November 1st, 1924, p. 803) prompts me to send the following report of a case I have recently seen.

I was called at 8 a.m. to see a married woman, aged 27, who was said to be suffering from severe abdominal pain and persistent vomiting. I found the patient to be extremely blanched, restless, and showing evidence of air hunger.

She complained of severe pain in the left side of the abdomen, high up under the ribs. I was informed that she had been perfectly well until about 9 o'clock the previous evening, when, as she was getting into bed, she was seized with violent abdominal pains and vomiting, and felt faint and helpless. She was alone in the house and was unable to attract the attention of the next-door neighbours, so that she remained in this condition until the return of her husband next morning.

She was, according to her menstrual history, about four months pregnant and was a primipara. When about four weeks pregnant she had been treated elsewhere for pernicious vomiting of pregnancy, and was laid up in bed for several weeks; her symptoms at that time were, as far as I could gather, very similar to those now present. Since that time she had been perfectly fit. There was no history of vaginal haemorrhage.

The radial pulse was running and impossible to count. The abdomen appeared rather distended, and there was dullness over the left side, but she was difficult to examine properly owing to the persistent retching and vomiting. There was a pyriform swelling extending up from the pelvis and just palpable above the symphysis pubis. She was admitted to the local cottage hospital, where she died shortly afterwards.

## Post-mortem Examination.

On opening the peritoneal cavity a small quantity of blood-stained fluid escaped; the left side of the abdomen was filled with an enormous blood clot extending from the region of the spleen. The clot was densely adherent to the stomach and intestines in many places, and it was impossible to detach it without rupturing the organs, thus showing that the condition must have started some time before, and possibly during the first month of pregnancy, when the patient became ill.

The spleen was about normal in size, but flabby and pale in colour. A small aneurysmal sac, which had ruptured, was found on the splenic artery, and the blood clot extended from this.

All the internal organs were extremely pallid and flabby. No other abnormalities were found. The pelvic organs were normal, and the uterus contained a foetus of about four months. The splenic specimen was shown to Dr. Piney, pathological director, Charing Cross Hospital, who confirmed the diagnosis.

## Reports of Societies.

### RADIATION THERAPY.

#### DISCUSSION IN ELECTRO-THERAPEUTIC SECTION.

WHEN Dr. Gilbert Scott was President of the Section of Electro-Therapeutics of the Royal Society of Medicine five years ago he suggested that a discussion should take place annually in that Section on the subject of radiation therapy. The fifth such discussion was held on March 20th, but the opening paper by Dr. Gilbert Scott on "Radiation, with special reference to the treatment of carcinoma of the breast by x rays," and a communication by Dr. J. H. Douglas Webster on "Results and problems in deep x-ray therapy," took up all the time available, and it was decided that the general discussion should be adjourned until the meeting of the Section in May.

Dr. STANLEY MELVILLE, the President of the Section, in opening the meeting, deplored certain attempts, made partly within and partly without the general body of radiologists, to divide radiology into two schools of thought, one supporting the old and the other the new therapy. Such a division was dangerous. Already surgeons were sending patients to radiologists with the proviso that they were not to be treated by the so-called deep therapy methods. He did not wish radiology in this country to be regarded as attached to any particular form of radiation. What people outside the ranks of radiologists were forgetting was that radiologists were increasingly inclined to view the matter from the biological standpoint, and that some very important research was taking place in that connexion; he instanced the experimental work on animals conducted by Professor Sidney Russ. More regard was being paid to the resistance of the tumour, the response of the surrounding tissues, and, above all—as a determining factor in the selection of the type of ray—the condition of the blood. Radiologists were not and must not be tied down to any particular type of radiation. No doubt a high-voltage radiation was wanted in many cases, but so was radiation of other kinds, and he would be very sorry to see two schools of thought, antagonistic to each other, arise. The radiologists were getting over many of their early difficulties, and he hoped they would resist this fissiparous tendency. He hoped also that light might be thrown on two questions: (1) Were radiologists spending too much time in considering the apparatus rather than the part to be irradiated? (2) Were they obsessed by the desire for rays of shorter and shorter wave-length? Were they thinking too much about voltage and too little about other factors? If all they wanted was radiation of greater hardness he did not doubt that physicists would be able to build machines which would furnish x rays of such hardness as to outdo by far the gamma rays of radium, but that did not seem to him to be the proper way to approach the problem.

Dr. GILBERT SCOTT then read the paper which is printed in full at page 596.

#### RESULTS AND PROBLEMS IN DEEP X-RAY THERAPY.

Dr. J. H. DOUGLAS WEBSTER (physician in charge of the Radiological Department, Middlesex Hospital) agreed with Dr. Scott and with the President that it was unfortunate in many ways that there should be a division between superficial and deep therapy. Such a division was quite legitimate from the point of view of the X-ray Protection Committee, but practical treatment was a different matter. In the prophylactic treatment of the breast, which was the subject he chiefly desired to speak about, what he called a medium deep therapy (that is, employing a voltage of from 100,000 to 150,000) was the most satisfactory.

#### Prophylactic Breast Treatment.

Dr. Webster went on to say that the problem of prophylactic post-operative treatment of cancer of the breast was different from the treatment called for after operation for cancer in most other sites. The presence of the air-filled lungs diminished the scattered radiation factor very

much at the pleura, and made it impossible with one application (except in extremely thin patients) to give a sufficient dose at the pleura without profoundly damaging the skin. Therefore breast prophylaxis had to be a cumulative treatment, prolonged over a number of months or even up to one or two years. The best results reported, so far as he was aware, were those of Anschütz and Hellman, relating to 240 cases, 77 per cent. of which were free from recurrence after one year, and 60 per cent. after three years of Group I patients at time of operation. Occasionally during the prophylactic courses the earliest signs of recurrence were discovered in the shape of enlargement of the opposite axillary or the supraclavicular glands, or, more rarely, nodules near the scar; in almost every case when such recurrences or suspicious signs appeared his practice was to change over to high-voltage therapy—that is, over 150,000 volts—and in a large proportion of cases with a successful result. Each of these patients was examined at six weeks' intervals for two years, and in only about 12 per cent. of cases did these earliest signs of recurrence fail to disappear. During the last two years he had paid special attention to the opposite axilla, following out Mr. Sampson Handley's theory of invasion of the opposite axilla by the lymphatics in the fascia, and very few opposite axillary enlargements had been encountered. Enlarged axillary and supraclavicular glands, of course, were not always malignant; when removed surgically they sometimes showed merely hyperplasia and appeared to be free from gross signs of invasion, but serial sections, he believed, sometimes showed, or at least suggested, an enlargement as a reaction to the very earliest invading cancer cells. In every case, therefore, in view of the fatal character of cancer of the breast—Leo, in the United States, had estimated that only 15 per cent. of all cases treated surgically were living at the end of five years—it was probably best to carry on treatment on the presumption of malignancy.

The technique to secure a comparatively homogeneous surface radiation of the breast was very difficult owing to the shape of the breast and the surrounding regions, and the great differences in the configuration of patients. It was entirely wrong to divide the area up into squares, according to one American method, for little strips between the marked-off portions were likely to receive no dose at all, and microscopic evidence showed that here the cancer cells remained organized; they were not degenerated as they were in the portions which had received the radiation. Radiation could be carried out in two ways: the first by radiation from one or more points at a great distance, 50 or 80 cm.; and the other—which was the one he preferred for prophylactic cases—based on Holzknecht's method of radiation over large surfaces, whereby the area from the supraclavicular to the umbilical level was covered by the rays from two or three points, at an angle of, say, 30 degrees from above and below, and from the side, and in most cases an additional dose was given into the apex of the axilla. This near method was more rapid and less troublesome to the patient, and he thought it gave as good results as any other.

#### Analysis of 336 Breast Cases.

Dr. Webster then gave statistics first of all of 148 cases of carcinoma of the breast which he had treated by the medium-voltage method, mostly following operation. If 30 cases were excluded because they had had only one or two treatments and had then been lost sight of, and 10 because they were inoperable, recurrent, pre-operative, or mastitis cases, the remaining 108 were analysed as follows: 34 (32 per cent.) had died; 36 were continuing treatment, and of this number 9 had already gone one year after operation and were apparently well; and 38 (35 per cent.) were now having no treatment, though they came up regularly for report, and apparently were well at the end of two years. If to these 38 were added the 9 just mentioned, the result was 47 cases (43 per cent.) of apparent successes—a good percentage considering the number of advanced cases at operation included in the series.

In addition to the above, 188 patients had been treated with high voltage (200,000 volts), in most instances combined with some areas with medium voltage. These were the most

severe cases (not prophylactic), the series including a number of inoperable breasts and recurrences, and they were also the most difficult to analyse. Of the 188 cases, 84 (45 per cent.) had died or had abandoned treatment and had been lost sight of, and 45 (24 per cent.) showed a good result and treatment had been discontinued. In 27 cases in which slight recurrences were noted during prophylactic treatment, 14 were now off treatment, recurrence, and only 3 had done badly. Ten groups among these 188 cases, dividing them according to the nature of the operation done or the type of the growth. Some cases of incomplete operation, with radiation immediately following, had done very well. He laid stress on the need for careful investigation of each bad result. The radiologist should make up his mind as to the reason for any fatal result, and whether any possible alteration of technique or treatment might have prolonged life. In nearly every case where the patient died the death was due to wider or deeper extensions of the disease.

#### "In Advance" Treatment.

During the last two years, Dr. Webster said, he had been feeling his way to what might be called the "in advance" method of treatment. In some sites this was a customary procedure, but in the breast it was very complicated. The method was based upon Mr. Handley's theory of lines of centrifugal lymphatic spread, and his aim had been to irradiate the lymphatic areas in advance of any clinical signs of the disease. Thus, if the axilla was involved, special attention should be paid to the supraclavicular triangle; if the latter was involved, radiation should also be given to the anterior mediastinum. If the tumour was in the inner quadrant of the breast, and radium had not been inserted at operation in the sterno-costal spaces, sternal radiation should be carefully carried out. If the tumour was in the lower quadrant of the breast the epigastrium and abdominal fascia and perhaps the hip on the same side should be irradiated. A primary breast case which he had treated some years ago, apparently satisfactorily for a year, ultimately died with hip metastasis. A prophylactic course, therefore, was not entirely routine technique, but was modified to suit the special requirements of the case. Several American surgeons had the lungs and spines of all breast cases radiographed before operation; certainly in some cases, even of very small breast tumour, invasion of the chest and spine could already be made out; he thought that this x-ray examination should always be done.

#### Factors Determining Recurrence.

Dr. Webster said that cancer of the breast offered one of the most satisfactory fields for the study of cancer, biologically and clinically, and the fact that patients came up even as long as eighteen years after operation with local recurrences at or near the scar made one hesitate to use the word "cure." Some patients treated had shown, after quiescent periods, a sudden flaring up of multiple recurrences, and this problem required much more study. Analysis of a large series of cases showed that many confidently expressed opinions in medical and lay journals were fallacious. A recent note in a medical journal stated that the greater number of cancer patients died during the winter, but among the patients who had died in his series of cases the deaths were very evenly divided between the different seasons. Recurrences had been noticed coming on after confinement to the house with bronchitis or sciatica, and patients who had done unusually well had been in several instances those who lived an open-air life, a circumstance which suggested that ultra-violet treatment might be tested as a means of raising the patient's resistance. Among the bad results were a number of patients who were really accepted in the terminal stages of the disease. In some instances radiation treatment might appear to accelerate death, though he saw no reason why, in the attempt to benefit some of the practically hopeless cases referred to him, the radiologist should not be given the immunity granted to the surgeon when faced with similar difficulties, and it was not right that the results of

the treatment in terminal cases should be held to afford a reasonable test of the value of any form of treatment. He mentioned one case of a gastric cancer in which the patient was in good condition, but in which, in view of her age, he decided not to give radiation treatment. The patient died quite unexpectedly two or three weeks after his visit, and had she been treated no doubt the radiation would have been blamed for the result.

#### Problems Awaiting Solution.

Dr. Webster went on to pose a number of problems:

1. Was there a stimulation dose? In plants it had been proved that growing seeds could be stimulated by small doses of x rays, but it was strongly disputed by Holzknecht and a number of others that stimulation could play any part clinically. At the same time there were some observations which suggested the contrary. In rodent ulcer on a convex surface like the forehead the centre could be more radiated than the edge with imperfect technique, and he had seen the edge growing rapidly after wrongly applied irradiation. In two radium cases a ring of nodules had appeared round an area to which radium had been applied for nodular recurrence.
2. Was it really better—and if so under what conditions—to give a maximal dose in a short time? In America the intense application of radium—500 millicuries of radium element applied for about one minute—had been employed on small rodent ulcers with good results. In other conditions the very opposite method gave excellent results with radium. The answer to this problem was not clear yet for either x rays or radium.
3. The physical and biochemical theories of action on which dosage and results depended had still largely to be determined.
4. A variety of opinions was advanced as regards the action on the cancer cells, some stating that radiation never acted directly on the malignant cell, or only acted through stimulating the surrounding tissues, and it was also claimed, as Dr. Scott seemed to believe, that it acted chiefly through a general effect on the whole body. In lymphosarcoma the rays seemed chiefly to act by the damage they did to the cancer cell, but in the breast they also stimulated connective tissue formation, and might also act largely by stimulating the resistance of the body.
5. Was radiation chiefly a local or a general action? Dr. Scott seemed to be giving up the local action theory and turning to the general. This might be a dangerous method, Dr. Webster thought, if given intensively. Local action was more certain than general, and its results had been proved in thousands of cases.
6. The relation of the tumour to the glands. He would like an opinion from radiologists as to whether they favoured the centrifugal or the centripetal method—that is to say, was it best to begin treatment in the opposite axilla or supraclavicular, and gradually work back to the primary growth, or to begin with the primary and go gradually out?

#### Conclusions.

Dr. Webster's conclusions were as follows:

1. Study of x-ray results and methods should be based on a large series of analysed cases, not on statements of results in a few selected cases.
2. The value of prophylactic radiation after operation seemed to him established. Cases treated promptly after operation practically never had the large inoperable local recurrences that were seen too often in patients who had no full post-operative x-ray treatment.
3. A medium-voltage technique for prophylactic breast work had given the best results hitherto published.
4. Any recurrences appearing should be treated with high-voltage radiation. He had seen a number of examples where the change over from medium to high immediately produced a satisfactory result, which treatment with medium voltage had failed to produce. The same sometimes happened with the change over from high-voltage x rays to radium. Sometimes, but rarely, the reverse—a change down—might prove beneficial.
5. A considerable number of cases had been observed in which early recurrences had completely disappeared with prompt radiation. This was a very valuable means of arresting the progress of the disease.
6. Operable and inoperable growths and recurrences had been arrested for considerable periods and inoperable tumours rendered operable.
7. The field of auxiliary therapy to radiation, whether arsenic, iodine, lead, or copper injections, organic extracts, or ultra-violet radiations, was one calling for much future hopeful work.

The discussion was adjourned until May 15th.

## VITAMIN DEFICIENCY.

THE resumed discussion on "Non-specific disturbances of health due to vitamin deficiency" took place at the Royal Society of Medicine on March 23rd, with the President, Sir St. Clair Thomson, in the chair. The report of the opening of the discussion appeared in the *BRITISH MEDICAL JOURNAL* of February 21st (p. 358). The four openers (Dr. Leonard Williams, Lieut.-Colonel R. McCarrison, Dr. W. Cramer, and Dr. G. M. Findlay) gave each an epitome of his previous contribution.

THE PRESIDENT remarked upon some "wise words from a wise old man" which had appeared in the *Times* above the signature of the late Sir Clifford Allbutt on January 6th last. Sir Clifford had written to support the advocacy of Professor Noel Paton for a richer flour, which, he said, would have advantages from the point of view of health, as well as the agreeable flavour which promoted digestion, and in the course of the letter he had asked whether any food could be more insipid than the present blanched loaf. He had gone on to say that vitamins were elusive bodies, but of their potency there could be no doubt, and it was probable they were eliminated with the offal. It was sometimes said (Sir Clifford had added) that any dietetic virtue which might be rejected in the bread was secured from her sources, but this seemed to him a chancy way of dealing with the staff of life.

*Vitamin Deficiency and Gastro-intestinal Infection.*

DR. WILLIAM HUNTER said that he had been greatly impressed by the exceptionally clear presentation of the subject by the opening speakers. What had appealed most to him was the pathological basis for the facts which three of them had brought forward. Reference had been made to gastro-intestinal changes consequent upon vitamin deficiency, to changes in the lymphoid tissue, and to the striking aplastic changes produced in the bone marrow. The changes described as atrophy of the lymphoid tissue and lymphopenia had particularly interested him. Lymphopenia could go on to such a degree that instead of a total of 2,000 lymphocytes per cubic millimetre they numbered only 400, or 20 per cent. The relation of vitamins to infection seemed to him a point of the greatest importance. Colonel McCarrison had shown how, consequent upon the withholding of vitamins, the resistance was lowered, more especially to any infections present in the intestinal canal, and he had illustrated his remarks by reference to amoebic dysentery, where the infection, which had been present in a harmless form, was, so to speak, awakened up into virulence when the vitamins were deficient. This failure of resistance seemed to the result directly of the pathological changes were not the result directly of the vitamin deficiency, but, in all cases, of infections, among which, to his mind, the streptococcal infection was the most prevalent, and potentially the most pathogenic to the human subject. From his own familiarity with pathological conditions, he fully supported the view taken by the openers as to the great importance of vitamin deficiency in favouring infection, and endorsed the arguments put forward by Colonel McCarrison in particular, that vitamin deficiency was a great factor in the causation of common intestinal disorders of many different kinds, seriously hampering nutrition and assimilation, and diminishing the resistance of the intestinal mucosa through the virulence of the pathogenic organisms in the tract, amongst which the streptococcal must, in his view, be considered the most important. The important thing to consider was the mischief which vitamin deficiency was doing in their own population, especially among children and young persons.

*The Theory Challenged.*

DR. ROBERT HENDERSON agreed with Dr. Cramer that the use of the term "vitamin" must be limited for the purposes of the present discussion to the three accessory food factors, A, B, and C. If it was extended, as Dr. Leonard Williams suggested, to mineral salts, catalysts, enzymes, and chlorophyll, not to say violet rays and electricity, the result would be hopeless confusion. When one was asked to believe that a deficient supply of these specific vitamins in the diet was a cause of widespread disorders of health,

it had to be remembered that the evidence which had been brought forward by the openers of the discussion in support of such a proposition was mainly experimental. It was very difficult to be sure that disturbances of health in animals fed on avitaminous diets were due solely to the absence of vitamins. Such diets were usually very abnormal in other directions as well. Some of them were "synthetic" diets; others—as one of the speakers had admitted—were deficient in proteins of high biological value, or had no proper balance of inorganic salts. Colonel McCarrison stated that his monkeys were taken from the Madras jungle and fed on an autoclaved diet, and that in these circumstances they developed various gastro-intestinal disturbances. But suppose the position reversed, and that the investigator was turned loose in the Madras jungle, and fed on a diet of raw fruits and vegetables—a diet rich in vitamins—was it not possible that in such circumstances he might also develop "a severe intestinal flux"? Apart from this, however, and granting for the sake of argument that the disorders mentioned were really due to deficiency of vitamins and nothing else, was there any real reason to suppose that comparable disorders were being produced to any extent from a similar cause in the ordinary community? The speaker doubted it; indeed, he simply did not believe it. He entirely agreed with Dr. Cramer that one could draw no hard and fast line between specific and non-specific disturbances of health due to vitamin deficiency, but that the former were only the final links in a pathological chain of which ill defined disturbances were the protagonists of the theory would have others believe, large numbers of persons were suffering from the early and non-specific disturbances, none of them ever reached the final link of the chain or exhibited the specific disturbance in its full-blown form. That this was true, in this country at least, could not be denied. He had himself, in twenty-five years' experience at the London Hospital, never seen a case of adult scurvy nor of beri-beri, unless imported from the East. Yet they were asked to believe that a deficiency of the antineuritic and antiscorbutic vitamins in the diet was an important cause of vague ill health in the community! One might as well be told that in a community in which poverty was widespread no one ever went bankrupt. This was particularly true of vitamins B and C. With regard to vitamin A, the case was a little different. Deficiency of this factor did not so much culminate in the production of a specific disease like beri-beri or scurvy (he regarded the case for rickets being a deficiency disease as still *sub judice*), as in interference with growth and development and with the power of resistance to certain infections. That impaired growth or low resistance to infections might sometimes be due to deficiency of vitamin A it was difficult to disprove, but he thought there was more evidence that when such disorders occurred in any class of the community they were due to a deficient total calorie value in the diet during the years of most rapid growth, rather than to deficiency of a vitamin which, after all, was so widespread in foodstuffs and so resistant to the effects of cooking as vitamin A. The disease xerophthalmia, which was known to result from a deficiency of this vitamin in the diet, was, after all, a rare one in this country, and he could not help thinking it would be commoner if the diet was really lacking to any extent in the fat-soluble vitamin. This was the true inference from the Denmark experience referred to by Dr. Cramer. The President had already quoted a wise English physician, and he, in conclusion, would quote a wise American one—Professor Emmett Holt, in his book *Food, Health, and Growth*:

"The physician can fall into no greater error than to assume that vitamin deficiency is the chief cause of all chronic nutritive disorders; just as not very long ago these were all referred to auto-intoxication. . . . The use of vitamins without definite indications will be popular for a period, but like other fads it will pass. With time and further investigation their true place will be determined."

*The Vitamins and Tuberculous Infection in Animals.*

DR. M. J. ROWLANDS reported on some experiments carried out on a large scale on an animal very much akin to the human being—namely, the pig. He claimed that he had been able by proper feeding to eliminate tuberculosis

from herds which, as shown by *post-mortem* examinations, were full of tubercle. He had fed the animals on food known to be rich in A, B, and C vitamins. Similarly with cows, if they were not fed on a vitamin-rich diet bovine tuberculosis was certain to increase. He had been able to eliminate tuberculosis in cattle by feeding them on a diet known to be rich in vitamins A and B. He kept his animals out of doors, but this did not suffice to prevent tuberculosis—he had to give them vitamin-rich diet as well. As a consequence of this feeding not a single tuberculous animal was to be found on his farm. In certain experiments on full and deficiency diets in pigs, the result of the examination of the stools had shown quite clearly that animals fed on a vitamin-full diet could absorb more nourishment from their food; they did not pass so large an amount of undigested food as did animals whose diet was deficient in vitamins.

#### *Terminal Stage of Vitamin Deficiency.*

Dr. F. PARKES WEBER said that, like Dr. Hutchison, he had seen many people in the out-patient class in the East End of London, and in his experience the terminal condition of vitamin deficiency did arrive. It arrived very often in the form of tuberculosis or of various acute infections. The people whom he had seen in his work as physician to the German Hospital, which covered a large area of the East End, might be roughly divided into two classes. The first were patients with digestive disturbances—disturbances connected with visceroptosis, mucous membranous colitis, and similar conditions, all of whom, without exception, suffered from constipation. In this class the terminal stage arrived in the form of death from tuberculosis or from various acute infections. The second class consisted of men, and sometimes women, of the muscular and corpulent type, who put on an enormous amount of fat, and in their case the terminal stage only too often was cerebral haemorrhage and arterio-sclerotic disturbances. This second class had excess of food, and probably sufficient vitamins; they did not suffer from the symptoms of avitaminosis. But there was little doubt that vitamin deficiency was a factor in the disorders of the first class.

#### *Recruiting Statistics.*

Dr. H. SCURFIELD was also of opinion that there was plenty of evidence of widespread derangements of health which might be due to vitamin deficiency. Was it not a fact that practically the whole nation suffered from constipation, resulting in fortunes for the vendors of patent medicines? Also, were not great numbers of the recruiting failures during the war to be assigned to rickets in childhood, rickets being caused, as there was much evidence to show, by defective diet? Recruiting failures were not limited to the war period. The figures for a recent year showed that among 80,000 men offering themselves as recruits for the army, 50,000 had to be rejected.

#### *Animals on Autoclaved Diet.*

Mr. ASLETT BALDWIN said that Dr. Hutchison had quoted one of Colonel McCarrison's experiments—that with the Madras monkeys—but had not told the whole story. He had said that the monkeys fed by Colonel McCarrison on the autoclaved food developed intestinal flux, but he had not added that other monkeys, similarly taken from the forest and kept and fed under identical conditions except that the food was not autoclaved, remained perfectly well. With regard to the absence of scurvy and beri-beri in this country, might not this be due to the fact that, although large numbers of the population did not get enough vitamins, it would be difficult to find a person who was absolutely deprived? He had discovered an interesting fact while feeding goldfish—that goldfish which for eight months had been fed only on crumbs of wholemeal bread remained well and vigorous, while other goldfish which had been fed on the crumbs of white bread had all died.

The PRESIDENT mentioned that at Midhurst Sanatorium it had been noticed that when patients left the tables sparrows came through the open windows and helped themselves, but that while these birds would eat as plentifully as might be of butter, they would not touch the margarine which took the place of butter during the war.

#### *Openers' Replies.*

Colonel R. McCARRISON, in replying to the discussion, took up the remark of one speaker on the relation of vitamin deficiency to cancer as found in native races. What he himself had seen with regard to cancer, and what he had stated elsewhere, was that cancer and chronic gastrointestinal diseases were generally very uncommon amongst certain races in the extreme north of India where the diet was well balanced and rich in vitamins. He had not generalized with regard to this, because his experience did not go beyond those particular races. Cancer was, he understood, quite as common among the people of Bengal, where the food was very faulty, as it was in this country. It was not a question of civilization as against want of civilization, or of native races as against Western races. What was of importance was that food should be well balanced and rich in vitamins and other essential substances, and he also thought that in the present state of knowledge or of ignorance, it would be as unwise to disregard the possible action which faulty food might have as a predisposing cause of cancer as to assert at the present moment that faulty food was the cause of cancer.

Dr. CRAMER said that Dr. Hutchison had really questioned the whole basis of the vitamin conception; he had said that the effects found in the experiments might be due not only to vitamin deficiency, but equally to other deficiencies. But the whole basis of the experiments was that everything else that was necessary was given to the animals—protein, fats, carbohydrates—in proper proportion; everything was given except these hypothetical substances, and yet the animals died. When a small amount of butter fat or yeast was added a rapid change at once came over the experimental animal. Dr. Hutchison had said that he did not see the terminal stages of this condition. But, surely, if the clinician saw an undernourished child who developed pneumonia he would describe the terminal stage as pneumonia, and so on. As to the Danish experience which the speaker had cited in his original paper, Denmark was an agricultural country; its main industry might be said to be the production of vitamin A, yet deterioration could be produced in the general health of a large population because too much of this vitamin A was being exported. Were not the same factors operating in this country? He protested that the fact that cases of beri-beri were not discovered here was no evidence that the whole population got a sufficiency of vitamins.

Dr. FINDLAY referred to Dr. Hutchison's statement that he had never seen a case of scurvy in an adult. The speaker was not a clinician, but in his very short course of medicine to get a degree he saw two cases of scurvy, not, indeed, in England, but in the country from which both he and Dr. Hutchison came (Scotland). A few years ago, also, he had the opportunity of investigating the effects of vitamin deficiency in an industrial school not far from Edinburgh. In this school, from 1902 onwards, there had been cases of very acute pneumonia; a boy would go down with an attack which perhaps ended fatally within twenty-four hours. In 1920, after the last outbreak, he went down and investigated the school. On paper the diet was excellent, but the method of cooking was unsatisfactory. To save expense the whole of the food was put into large cauldrons, the lids of which were screwed down, and the food was allowed to stew under pressure for three or four hours. On investigating the medical history of the school one found, in addition to the pneumonias, that there had been, also from 1902, cases of conjunctivitis—or so they were put down in the records—very chronic, and not to be cured by washing out the conjunctival sacs in the ordinary way. These two conditions—the conjunctivitis and the pneumonia—were practically the only conditions from which the boys seemed to suffer. On his recommendation the Scottish Office sent down orders for cod-liver oil and raw swede juice to be given, and since then no new cases of pneumonia had occurred. He also related some particulars of experiments on rats and guinea-pigs, all of them inoculated with tuberculosis, but some of them placed on a vitamin-deficient diet, and others not. The animals on the faulty diet died much more rapidly from tuberculosis than did those which had a sufficiency of vitamins.

At a meeting of the Medical Society of London held on March 23rd, with the President, Dr. EGSTACE M. CALLENDER, in the chair, Mr. L. BATHE RAWLING opened a discussion on oxaluria.

Mr. Rawling apologized for being in the position of opening a discussion on a subject which was medical in so many aspects, and he proposed to confine himself to the surgical side of the question. He had inquired among surgical colleagues, but he had obtained little information, although oxaluria was a condition which surgeons should bear in mind when confronted with certain symptoms. Mr. Rawling then dealt with the abdominal manifestations sometimes associated with oxaluria. He described the case of a house-surgeon who suddenly presented all the appearances of an acute intestinal obstruction, with a distended abdomen, vomiting, and absolute constipation. A laparotomy was performed, but nothing abnormal, save very distended intestines, was found. The patient made a rapid recovery, however, and the history showed that he had suffered from attacks of haematuria in the past, and some time after this attack of abdominal symptoms he passed an oxalate calculus. It had been noted, in reference to the urine in this case, that oxalate crystals were present, but their significance had not been appreciated. Two points of interest arose from this case: the patient stated that he did not feel as ill as he would have expected with acute intestinal obstruction, and, secondly, morphine, which had been given for the relief of pain, had undoubtedly helped to produce the abdominal symptoms. Mr. Rawling had seen similar cases since this one, but never so acute. He believed that the milder abdominal symptoms were due to the flatulent dyspepsia frequently associated with the condition of oxaluria. Reflex stimulation from the kidneys and ureteric tract might lead to inhibition of peristalsis of the intestine. The administration of morphine would further exaggerate such symptoms of intestinal obstruction, and thus error might arise if examination of the urine was omitted in such a case. The speaker then referred to a case of uraemia which had presented symptoms of subacute intestinal obstruction; such a case was related to the oxaluria cases referred to previously. With reference to the occurrence of oxaluric haematuria, the presence of crystals and blood in the urine, and the symptom of pain, frequently suggested the presence of a calculus. The haematuria caused by oxalates was sometimes painless, or, on the other hand, might be associated with severe colic and bladder symptoms. He referred to the case of a physician who had an attack of haematuria following the eating of too many strawberries. This, he found, could be prevented by eating duck and green peas at the same meal, for peas were apparently rich in magnesia and abolished the deleterious effects of the fruit! Mr. Rawling finally dealt with the question of a urethral discharge associated with oxaluria. Such a discharge varied from a mild purulent discharge, and was often mistaken for gonorrhoea. Vesical and rectal tenesmus might also occur. A microscopic examination of such a discharge would reveal the cause.

Sir WILLIAM WILLECOX said that he proposed to deal with the medical aspects of oxaluria. He had been struck with the remarkable absence of any references to this subject in recent literature, as he considered it one of great importance from the medical as well as from the surgical point of view. Oxalic acid was, he said, a normal constituent of the urine: an adult in health passed about 15 to 20 mg. of oxalic acid in twenty-four hours. If this quantity rose to about 30 mg. then this oxaluria became pathological. Under normal conditions blood contained this substance in the form of calcium oxalate, probably in a colloidal state, and crystals of calcium oxalate excreted in the urine were small, colourless, and usually of the "envelope" shape, the "dumb-bell" and "disc" forms being rarer and always in an alkaline or amphoteric urine. If the urine was acid as a result of the presence of sodium acid phosphate, calcium oxalate was usually in solution, but if above 20 mg. was being excreted in the twenty-four

hours it would crystallize out, and even when present in normal quantities in slightly acid or alkaline urine it would likewise be deposited. In cases of oxalic acid poisoning the acid might be present in the urine in a free state, as it also occurred in the liver, kidneys, and spleen, leading to a decalcification by combining with any calcium present. In chronic oxalic acid poisoning a condition similar to rickets might be brought about by such a decalcification process. In these cases the renal tubules, but not the glomeruli, were found to be full of crystals. In normal conditions the blood contained amply sufficient calcium and magnesium to deal with all the oxalic acid absorbed. Oxalic acid could be formed by the oxidation of carbohydrates, and also by the oxidation of proteins, while it was probable that it could also be produced from fats, since the administration of glycol to a normal person would greatly increase the amount of oxalates in the urine. A diet of milk and sugar alone would give rise to oxaluria, and a case had been recorded where a diet consisting of milk and sherry frequently associated with gastric dyspepsia or with colitis, and in both cases was due to the excessive fermentation of carbohydrate which occurred in these conditions in the gastro-intestinal tract. Lazy people, living in stuffy rooms, under defective hygienic conditions, were liable to get oxaluria. An idiopathic form of oxaluria had been described, due to some inborn error of metabolism. The question of foodstuffs containing oxalates was important, although there appeared to be a great difference of opinion on this subject. About 10 per cent. of the calcium oxalate ingested in food was excreted in the urine, and if a person was subject to oxaluria from defective metabolism such an excess might give rise to a greatly increased output. Foods containing oxalic acid, usually as calcium oxalate, included spinach, rhubarb, sorrel, beetroot, dried figs, certain beans, tea, cocoa, chocolate, pepper, and adulterated coffee. There was a constant fight going on in the body between the calcium and magnesium elements for possession of oxalic acid. Hence if there was a lot of magnesium ingested it grasped the oxalic acid and soluble magnesium oxalate was formed, and "oxaluria," in the sense of attacks of pain due to the insoluble calcium oxalate crystals, did not occur. Hence it was important in these cases to choose food which was rich in magnesium and comparatively poor in calcium, such as meat, flour, nuts, apples, peas, and potatoes, while foods in which the reverse was true and which should be avoided included milk, eggs, spinach, cauliflower, cabbage, grapes, sorrel, strawberries, asparagus, and pineapple. The speaker thought that the tomato had been much maligned, since its content of oxalic acid was very small. Symptoms of oxaluria were frequently absent in many cases where a deposit of oxalate crystals occurred. In hot climates, where the urine was frequently became concentrated, attacks of pain similar to renal colic often occurred, and were probably due to oxalate crystals. Oxaluria might be associated with a condition of mental depression and hypochondriasis with "real crisis of neurasthenia" which had long been known to be due to oxalate crystals. In treating this condition attention must be paid to the intestinal and gastric dyspepsias. Gastric lavage, doses of aperients such as Epsom salts, general hygienic treatment, with diet along the lines already indicated, were all important, and water should be freely drunk, attention being paid to the decalcification of hard water in districts with hard water supplies.

The President said that he had been struck with the frequency of oxalate crystals in the urine. He pointed out the danger of jumping to a conclusion because of the presence of such crystals. Dr. H. A. DES VOEUX thought it would be more correct to say that oxalate crystals were common in abnormal urines of whatever type. Any condition leading to the production of pus in the renal passages would give rise to an increase of oxalates in the urine. He recounted a case of oxaluria in a man of 80 associated with nightmares. Dr. T. J. HORSER inquired if there was any relation between oxaluria and orthostatic albuminuria. Dr. F. PARKES WEBER asked whether it was not the case that the presence of blood in the urine from any cause gave rise to an increased amount of oxalate crystals.

Mr. J. E. H. ROBERTS said he had been intending to ask whether the "tomato gall bladder" of certain American writers was due to oxaluria, but apparently the tomato had been freed from blame in this respect.

Sir WILLIAM WILLEON, in reply, pointed out that the presence of albumin or blood in the urine might, by its physical action, induce the crystallization of the oxalates. He thought the occurrence of oxaluria in neurasthenics was due to their intestinal toxæmia.

Mr. RAWLING also replied briefly.

### INFANTILE MORTALITY.

A MEETING of the Section of State Medicine of the Royal Academy of Medicine in Ireland was held on March 13th. The President, Dr. N. M. FALKNER, quoted Newsholme's dictum that infantile mortality was "the most sensitive index of social welfare and sanitary improvement which we possess." He referred to the decline in the infantile mortality rates of England and Wales from 158 to 69 in 1923, and mentioned the result of Dr. Wheatley's inquiry, which attributed this decline to child welfare centres and maternity visiting.

Dr. BRIAN CRICHTON, in a paper on infantile mortality, stated that the country was to be blamed for neglecting its greatest asset, the child. The responsibility of the State consisted in the supply of financial aid to municipal and other bodies for the maintenance of welfare centres, the feeding of school children, and the like. He compared the infantile mortality rates of various English towns with that of Dublin (125). To produce a healthy child, healthy parents, healthy surroundings, and good food were necessary. The greater portion of the centre of Dublin was hygienically bad and to be condemned. No more than 50 persons should be allowed to live on each acre, but in some wards in Dublin the number per acre was as high as 117, or even 138. No factory could exist under the conditions which were forced upon the infant population. The first and greatest evil to be remedied was the housing question. The Government had done something, but much more remained to be done. Dr. Crichton thought that the penalties for the sale of dirty milk were negligible compared with the harm inflicted on children by dirty milk. The mothers, in order to nurse their children, required good food; the cost of this was far too high, apart from the economic questions due to unemployment. He thought there was need for an inquiry into the prices charged for such foods as meat, butter, eggs, and milk by the middleman. The influence of sunlight and air on health was so well established that the need for more parks and open spaces was evident. Dr. Crichton then outlined a scheme for the improvement of child life in Dublin. Use should be made of the existing maternity hospitals in Dublin to which mothers had been accustomed to go for advice. Attached to these there should be welfare centres, both ante-natal and post-natal, where the mothers could be advised as to the health and feeding of their children, and food could be supplied at as near cost price as possible. Almoners and specially trained district visitors could go from these to visit the infants in their homes. These centres would also be very useful for the training of students and nurses. He pointed out the need of special schools for mentally deficient children, and also of open-air schools for delicate children. He added that the death rate among illegitimate children was six times that of legitimate children, and thought that more control should be exercised over women receiving nurse children.

Sir JOHN MOORE said that the infantile mortality under 1 year of age in 1923 was 66 per 1,000, and was much higher in boys than in girls, the male infant being probably more fully developed at birth than the female. The death rate among female children was 60 per 1,000, and among male children 73 per 1,000. It was the bounden duty of every mother to feed her child during the first nine months of the child's life, but this duty was very often disregarded. Recently there had been much use of milk which was contaminated, or preparations of milk which were probably very often poisoned. Child welfare in Dublin had made great progress, largely owing to the work of district

nurses. Remarkable results had been obtained at the Clieverstown Convalescent Home in the case of children between the ages of 3 and 5.

Professor J. W. BIGGER compared infantile mortality in Ireland with that in England. In the Free State, in 1923, this was 66 per 1,000, while in England and Wales it was 69 per 1,000. In the year 1915 the mortality in Ireland was 92 per 1,000, so the infantile mortality rate had been greatly reduced since then; in that year in England and Wales it was 110 per 1,000. In 1904 in Ireland it was 100 per 1,000, and in England and Wales 145 per 1,000. If this rate of reduction continued England and Wales would soon have a lower infantile mortality rate than Ireland. He felt that Ireland at present was too contented with her position; because it was said that the Irish infantile mortality rate was much less than anywhere else, nothing was being done to reduce it further. It had been recognized in England and Wales since 1904 that the rate there was too high, and successful steps had been taken to bring it down. If this had been done in Ireland, the rate in 1923 would have been only 47 and not 66 per 1,000. Whooping-cough caused 3 deaths per 1,000 births, probably because children did not get proper nursing in the latter part of this illness. Bronchitis and pneumonia also accounted for much of the infantile mortality, again due, probably, to the lack of good nursing. Diarrhoea, enteritis, and convulsions were very often caused by bad feeding. Breast-feeding would prevent many deaths. Premature birth was the cause of about 6 deaths out of every 1,000 births, and if Dr. Crichton's scheme of establishing pre-natal schools in connexion with the maternity institutions in Dublin could be brought into existence many of these deaths would not occur. Housing in Dublin was still deplorable, but he hoped that at last something was being done to make it better. To bring up children healthily in a tenement house was very difficult, and he agreed that it was necessary to provide open-air schools and more sunlight for children. The rural child had a better chance, even during the first seven days of life, than had the urban child.

Dr. R. H. MIEKS referred to the large number of sickly, wasting children in general hospitals; several months were required to effect any improvement in their condition, and bad cases of marasmus took a year to cure. He referred to the danger of the "tuberculosis houses" of which there were so many in Dublin, and the number of children suffering from tuberculosis, owing, probably, to the unhealthy state of their surroundings. This was not the fault of the parents, for no better houses were obtainable. In some families nearly all the children were suffering from tuberculosis; very few patients were willing to go to sanatoriums, and they came home very quickly. He thought that the question of improving sanatoriums should be taken up. There would be no definite improvement in the number of cases of tuberculosis amongst the poor until better housing conditions were established. He thought that the "nursing out" of children should be avoided if possible, as a great many infantile deaths were due to deliberate starvation under these conditions. He referred to the difficulty in procuring good milk, especially among the poor.

Professor J. T. WIGHAM said that it had been asked why infantile mortality should be avoided, since an easy way of limiting the population was to allow children to die soon after birth. It had been pointed out that at present there was a great excess of unskilled labour, and that many town-born children grew up to become unskilled labourers. The answer to such a question was that infantile mortality was an index of children's disease, and that a great many children who did survive from disease in childhood were unfitted by it to develop into healthy citizens. Great efforts were being made to improve the housing conditions in Dublin, and the help of every citizen was required. He referred to the work which was being done by Mr. Hall, and also by Messrs. Guinness. The Dublin Corporation was building very extensively on the banks of the Liffey, above Island Bridge; and Mr. Hall had stated that if he could procure £10,000 all the houses would be built before the end of June.

Dr. P. DE BURCA said that had housing and food (especially milk) were not the causes of infantile mortality, but were rather the symptoms of a disease. Decent housing and food would never be obtainable so long as the absolute necessities of life were produced for profit and not for use. Great care was taken to see that the water was pure, and that contamination was avoided. If that was done with water, why should it not be done with milk and bread? Before the infantile mortality was improved it would be necessary to improve the conditions under which the working man lived, and to enable him to get a living by means which did not bring him into competition with his fellow working man.

Dr. KENNEDY CAHILL drew attention to the appalling death rate amongst children who were "hoarded out." The population in France was stated to be low, because contraception was in vogue and the people decided not to have large families. He believed, however, that the birth rate there was as large as it was in England, but the death rate in France during the first few months was so high that the population did not increase. He thought that a bonus was given to every child that was born in France; if this money was given to pre-natal clinics it would be used for a much better purpose.

### INSANITY AND DIVORCE.

At a meeting of the Medico-Legal Society, held in London on March 17th, with Lord Justice ATKIN, the President, in the chair, Dr. NATHAN RAW read a paper entitled "Three suggested grounds for divorce: (1) hopeless insanity; (2) chronic inebriety; (3) penal servitude for life."

Dr. Raw said, while he was not in favour of weakening the marriage tie in normal conditions, circumstances often arose unfortunately where it was necessary to consider the desirability, urgency, and importance of making some alteration in the present divorce laws, in the interest both of the State and of the children, and more directly in the interest of the parties immediately concerned. The Royal Commission on Divorce, appointed in 1909, although divided on the cardinal points, was unanimous in the findings that nullity of marriage should be decreed in cases of (a) unsound mind, (b) epilepsy and recurrent insanity, (c) venereal disease. In April, 1920, he had an opportunity of pressing these three grounds in a debate in the House of Commons, but, although they were generally accepted, the motion was lost by forty-one votes, as the House was not prepared to accept the entire majority report. In Great Britain and Ireland there were 150,000 persons certified as insane under the Lunacy Acts, and of that number, almost 50,000 were suffering from dementia. Dementia was incurable, and he thought that this condition should be considered a ground for divorce. Between 20,000 and 30,000 of these people were married, and in a very large number of cases the husband or wife might not know his or her spouse: in fact, a great many of them could not realize that they were married. He had never known a case of dementia to recover after it had lasted five years. After that period elapsed, he suggested that the patient should be examined, at the request of his or her spouse, by a body of medical experts, who would then be satisfied as to whether or not the case was curable. If incurable, then it might be made a ground for divorce. These cases were particularly hard upon the poor. Another form of mental disease, epilepsy, should be a ground for prohibiting marriage to the sufferer.

Regarding habitual drunkenness, with which he associated the ground of hopeless addiction to drugs, he said it was proposed that, in such cases, after a separation order had been granted and had been in force three years, and the drunkard still continued without any sign of improvement, then the other spouse might petition for divorce. The ruin of the children of a drunken father or mother could often be traced to the evil of parental example. It was authoritatively stated that 90 to 95 per cent. of habitual drunkards died drunkards, and that if the state of drunkenness continued for three, four, or five years without improvement there was practically no hope of permanent cure.

The question of imprisonment for felony was more difficult, and different countries took varying views on the subject. The Commission was in favour of divorce for the spouses of felons whose death sentence had been commuted. He had the greatest respect for those who supported the ecclesiastical view that marriage was an indissoluble tie, but he thought that the three grounds he had mentioned were in a different category. They could not be foreseen at the time of the marriage, and one party should not be compelled to suffer for life for something for which he or she was in no way responsible and which had rendered married life impossible.

In the discussion which followed, Lord Justice ATKIN said, whilst they all agreed that it was important to the State to maintain, as far as possible, family ties, there were cases where it was necessary that the tie of marriage should be dissolved, otherwise family life was discouraged. If insanity for which the individual was not to be blamed was admitted as a ground for divorce, then there were other grounds which were equally not the fault of the individual, which would also have to be considered. The proposition ought not to stop at insanity. Then, as to the ground of a view of matrimonial life, more serious offences, such as indecency, attempted rape, and blackmail. Then, again, while incurable insanity was certainly a cause which would make a tremendous appeal to everybody, even there one would like to know whether the medical profession was quite satisfied that it could always with certainty say that the insanity was incurable. Chronic inebriety seemed to him to present even greater difficulties. He himself knew of cases where apparently incurable drunkards had in fact been cured; and the existence of the family tie would be the great motive in many cases for curing oneself of drunkenness.

A MEETING of the London Association of the Medical Women's Federation was held at the Elizabeth Garrett Anderson Hospital on March 10th, Miss M. CHADBEURN in the chair. Dr. DONOTY HARE, in a paper on the value of the electrocardiograph to the physician and surgeon, said that the apparatus she used at the Royal Free Hospital was similar to the original Waller instrument, invented in 1897, with the exception that the capillary electrometer was now replaced by the Einthoven string galvanometer. While no mechanical means of investigation should ever replace careful clinical examination, there did undoubtedly exist cases with few physical signs, in which the additional information supplied by the electro-cardiograph was a weighty factor in the diagnosis. She referred to the ease of obtaining a reading without discomfort to the patient, the equipment at the hospital making a complete examination possible with the patient in bed, if necessary. She then showed a series of interesting diagrams and records of clinical cases, selected mainly to bring out the special points which this method of investigation elucidated. The normal tracing was by no means simple, and the limits of variability of the normal had not yet been fully established. Cases illustrating the value of the tracing in the determination of the condition of the myocardium were described. It was here that the electro-cardiologist could be of help to the surgeon and obstetrician, since a definite opinion as to the patient's fitness for operation could be given from a study of the muscle element in the curve. A series of cases showing lesions of the conducting mechanism were then described. A short discussion followed, in which Dr. M. E. DALBY, Dr. M. DOBIE, Miss ALICE BLOOMFIELD, Dr. E. H. LEPPEL, Mrs. FLEMING, and Miss M. CHADBEURN took part.

At a meeting of the Chelsea Clinical Society at St. George's Hospital on March 17th, when the President, Dr. GORDON LANE, was in the chair, Dr. LEONARD WILLIAMS gave an address on the diseases of old age. He said that constipation and errors in diet, in the way chiefly of excess, were in great part responsible for senile troubles. He described the ductless glands and the control they exercised, and expressed the opinion that the adrenal was at fault in many cases of disease in the old man and woman. Mr. KENNETH WALKER thought that in some cases ligature of the vas deferens was a useful operation, but that grafting of the testicle did a great deal of good. Mr. IRON BACK said that he could confirm this of about 30 per cent. of his cases, but in a great many grafting had not fulfilled expectations. Mr. RALPH THOMPSON related some results of dissections of the ductless glands.

## Reviews.

### MEDICAL HISTORY OF THE WAR.

THE fourth volume<sup>1</sup> of the *General History of the Medical Services* during the great war is the last of the series, and thus brings the formidable task undertaken by Sir WILLIAM MACPHERSON to a close. In its main features it is identical with its predecessors, but differs from them in the multiplicity of the subjects considered and in the fact that it bears on its title-page, in addition to the name of Sir William Macpherson, that of the officer who acted as his assistant throughout the whole undertaking. This is Major T. J. MITCHELL, D.S.O., R.A.M.C., to whom also the authorship of certain chapters in the present volume is definitely assigned in its preface. Leaving out of account a large number of sketch maps, charts, diagrams, tables, and photographs, the text runs to a little under six hundred pages, which are made to cover the operations on seven widely separated fronts, and also a record of all the means—from hospital ships to sledges—for the transport of the sick and wounded employed anywhere during the war.

The Mesopotamia operations receive the lion's share of attention, ten chapters and some 238 pages being devoted to them. The share is even larger if the account of the work done in North-western Persia, which was an offshoot of that in Mesopotamia, be included. Nor does the largeness of this share seem remarkable when it is remembered that the Mesopotamia operations lasted practically four years, and from start to finish were full of incident and occasion for effort in the way of frequent contact with the enemy, hazardous movements of troops, very difficult transport, and the constant presence of unavoidable causes of disease. Included is an account of the siege of Kut-al-Amara, and the whole chapter, quite rightly, exclusively devoted to it is perhaps the most attractive in the whole volume. As is not always the case elsewhere, the reader at once feels that he has a clear idea of the nature of the country in which the operations took place, of the problems by which the medical service was faced, and of the difficulties encountered in meeting them.

The next largest share, four chapters and about 102 pages, goes to the operations which originally had Salonica as their base, but which eventually moved or extended to the Black Sea and the Caucasus. It is less easily read than the other, but this is perhaps natural since the force engaged was in the later stages split up into so many different parts and had its affairs complicated, more particularly on the medical side, by having to deal with Greek, Serbian, and eventually Russian sick and wounded. These four chapters are, like the rest of the volume, well supplied with photographs and sketch maps, but not all the latter are adequately explained either in the text or by the under-lettering. Many generations, for instance, of students at the Royal Army Medical College are probably destined to be puzzled by a sketch map of an unnamed brigade area which shows a field ambulance main dressing station in a line of regimental aid posts. The long-drawn-out and somewhat desultory warfare over a vast area in East Africa with disease as the chief enemy also receives four chapters, but these are somewhat shorter. The rest of the operations described—namely, those in the scorching Aden Protectorate; in North Russia amid ice and snow; and on the Gallipoli Peninsula—are each given one chapter apiece; in the last named case a long one of some sixty pages.

Finally comes a well illustrated account of all the methods of transport employed for strictly medical purposes on the various fronts held by British troops at one time or other during the war. Apart from its other merits, this chapter is intrinsically illuminating in regard to the diversity of conditions with which the medical services had to contend. Included in the chapter is a useful description of the boats, barges, and craft used on rivers, canals, and lakes

for moving the sick and wounded. In Franco the inland waterways were so utilized, not of necessity as on some other fronts, and it may be doubted if those who played an executive part in barge transport would fully share the favourable opinion that seems to have been formed by those more highly placed. The Italian overhead cable or Teleferico system of bringing wounded persons or goods from elevated situations also receives notice. It is said to have been occasionally used by the medical service of the Italian Expeditionary Force for the transport of severely wounded men, but according to our information this is a mistake. Only one of the three fronts successively occupied by the British in Italy lent itself to the system, and here, apart from the intrinsic drawbacks of the method, any temptation to use it was negated by the fact that the D.M.S. had placed an advanced operating centre, provided with a hundred beds, just under the rear edge of the mountain and alongside a first-class road devoted solely to downward traffic.

At several places in the volume reference is made to the dispatch of officers specially charged to bring about improvements or reforms in the medical situation on certain fronts and to the good results that ensued. It is to be hoped, however, that readers will not assume that such missions necessarily connote incapacity on the part of medical officers already on the spot. The occasion for them can never arise until much experience of local conditions has been gained, and the influence on headquarters of the emissaries concerned is apt to be much more potent than any that the D.M.S. of an army in the field can make sure of being in a position to exercise. However good an administrator a D.M.S. may be, his position is always one of much delicacy. This will be evident when it is remembered that ordinarily he can rely on there being considered by his commander only such version of his views as an intermediary may choose to convey; at all times also the service he commands is dependent for its ability to work at all on the co-operation of other branches, and this may be only grudgingly afforded unless it happens to be known that the D.M.S. has the ear of the commander. Worse still, a D.M.S. may be retained in the position of a convenient scapegoat should things go wrong, but ordered to take up his quarters at such a distance from the centre as to make it impossible for him to form or tender any balanced views at all, or even know what his own units are doing. Arrangements of this kind are, to use a colloquialism, simply "asking for trouble" in the way of undue wastage of man power through preventable disease and for loss of moral through undue suffering of individuals. This is the one clear administrative lesson to be derived from the work of the medical services between 1914 and the end of the war as set forth in the official history whose concluding volume has been the subject of this note. Yet it is a lesson of which the Army Council either remains in ignorance or to which it is unwilling to give heed.

### A GLASGOW MANUAL OF OBSTETRICS.

THE volume styled *A Glasgow Manual of Obstetrics*,<sup>2</sup> by Dr. S. J. CAMERON and a group of his colleagues on the staff of the Glasgow Royal Maternity Hospital, is of considerable interest as a presentation of methods employed in that very active institution, and it will be specially useful to their students. It is perhaps a little brusque in its dogmatism. Starting with the relation between ovulation and menstruation, it says that "the two functions usually occur simultaneously is undoubted." If the word "simultaneous" refers to the moment of rupture of the follicle and that of the onset of the menstrual flow, there is a fairly important volume of opinion ranged with Schroeder, who describes them as alternate. The short introductory chapter on embryology suffers a little from the difficulty of choice between detail that should be stated and that which should be left to recollection, but is probably adequate to the needs of those for whom the authors write.

In the chapter on the physiology of pregnancy one-third is devoted to metabolism and the ductless glands, and shows

<sup>1</sup> *History of the Great War, based on Official Documents. Medical Services: General History. Vol. IV. Medical Services during the Operations in the Gallipoli Peninsula; in Macedonia; in Mesopotamia and North-West Persia; in East Africa; in the Aden Protectorate, and in North Russia; Ambulance Transport during the War.* By Major-General Sir W. G. Macpherson, K.C.M.G., C.B., LL.D., and Major T. J. Mitchell, D.S.O., R.A.M.C. London: H.M. Stationery Office. 1924. (Demy 8vo. pp. xv + 711; illustrated. 25s. net.)

<sup>2</sup> *A Glasgow Manual of Obstetrics.* By Samuel J. Cameron, M.B.Glas., F.R.F.P., and S.G., Archibald N. McLellan, M.B.Glas., L.M.Dublin, Robert A. Lennie, M.B.Glas., John Hewitt, M.B.Glas. London: Edward Arnold and Co. 1924. (Med. 8vo, pp. xvi + 573; 214 figures. 21s. net.)

that, while the writers are well aware of the work that is going on in these subjects, they have the usual difficulty in arriving at a definite interpretation. All through the volume they give evidence of keeping in close touch with laboratory work, and they quite naturally refer to the researches that are in progress in Glasgow itself. In the chapter on toxæmias an account is given of the numerous tests which have been proposed for the measurement of acidosis and of the vital functions of kidney and liver, but in deciding for or against induction of labour clinical evidence, including blood pressure, is at present relied on, and a like attitude of open mind is maintained with regard to the various etiological theories. The statement that in the urine in acute yellow atrophy of the liver "crystals of leucin and tyrosin are present" is more interesting as an historical reminiscence of Frerich's initial paper than useful in the diagnosis.

Glasgow Maternity Hospital has a large ante-natal department with twenty-five beds, and it is rather disappointing that the authors have not taken their opportunity of giving a unified sketch of the preventive work that can be accomplished there, especially in the control of position and presentation. On this the improvement of domestic midwifery, which is needed in Glasgow doubtless as well as elsewhere, is dependent. The index gives "Malpresentations, p. 335." There, in the chapter on constricted pelvis, we read only: "Malpresentations and malpositions are more common than in a normal pelvis . . ." but it is just to the writers to say that other passages occur in which the theme is touched. In the same chapter several ages and three plates from a recent paper by Cameron and Hewitt are devoted to the question of head-brim fit, and raise in the mind a doubt whether, after all, Glasgow doctrine is so far unified as to justify the full implications of the title of the book.

The practical parts of the book are clear, and based on the wide experience of the writers, who also draw on their wealth of material to furnish good illustrations of many conditions of great interest which others may not have met. The diagrammatic drawings of Mr. A. K. Maxwell are clear and emphatic, and the type is good. The proof-reading has been unfortunate. We find "antiflexed" (p. 36), "muscular succurus" (pp. 48-49), "uroinin" (p. 184), "sagittal" (p. 506), and the famous writer on deficiency diseases has given place to the scion of a new clan "McGarrison" (pp. 30-31). References to original papers are rarely given.

### GOLD TREATMENT OF TUBERCULOSIS.

Those of our readers who have been following the promising researches which are being carried out in Denmark on the treatment of tuberculosis with gold preparations will be glad to know that a copy of Professor MOELLGAARD'S book, *The Chemotherapy of Tuberculosis*,<sup>3</sup> is available in English. These researches have aroused a great buzz of interest in Denmark (see *BRITISH MEDICAL JOURNAL*, November 22nd, 1924, p. 961), the echo of which is passing from one country to another. We have commented on this work whenever new information was at hand (*BRITISH MEDICAL JOURNAL*, November 8th, 1924, p. 870, and January 24th, 1925, p. 176), and we hope to publish in an early issue a paper on the experimental and clinical evidence by Professor Moellgaard himself.

The title of the present book does not describe completely the line of treatment Professor Moellgaard has introduced; its distinctive feature is the destruction of tubercle bacilli by a sodium gold salt, accompanied by a neutralization of the tuberculous toxin liberated from the bacilli by injecting at the same time an antiserum. This salt has for convenience been named "sanocrysin." Warnings have repeatedly been given of the danger which may arise from rapid destruction of tubercle bacilli within the tissues of a living animal: sanocrysin, injected into a tuberculous animal, causes the

death of living tubercle bacilli, with the result that the whole system is flooded by the liberated toxin. To neutralize this intoxication Professor Moellgaard has prepared an antiserum, and it is the combined use of an agent lethal to the tubercle bacillus and of protective serum that gives originality to this well conceived method of attack. We read in Moellgaard's book that when sanocrysin is injected into tuberculous guinea-pigs they die almost invariably, showing signs and symptoms of tuberculin shock. Administered to larger animals, such as calves, goats, and monkeys, sanocrysin gives rise to a definite train of symptoms—albuminuria, myocarditis, oedema of the lungs, and fall of body temperature, leading to death. This fatal shock may be warded off by injection of the blood serum of an animal suffering from chronic retrogressive tuberculosis or one artificially immunized. The injection of sanocrysin into a tuberculous animal may be made less dangerous if the protective serum is given earlier, but it does not appear that all upset can be avoided, for fever, nausea, and focal reactions are almost inevitable. More accurate dosage and a larger experience is teaching the Danish workers how these reactions may be lessened.

From what has been said it is obvious that Moellgaard's methods must be employed cautiously in the treatment of human tuberculosis, and no one is more insistent on this account of a large number of cases of human tuberculosis treated in various Danish hospitals and sanatoriums. We cannot summarize these carefully tabulated records, nor would it be just to do so, for the work is still in an experimental stage, so that it is likely to be handicapped rather than advanced by too early definition. Sufficient to say that there is plenty to guide physicians who seek to learn Moellgaard's methods, and that a careful study of these Danish cases should be made before sanocrysin is used in medical treatment, in order to learn which cases are suitable and the correct doses to employ. The book is lavishly illustrated and arranged in an orderly manner, but loses by the absence of an index.

### ENCYCLOPAEDIA MEDICA.

We have recently received the last volume (Tn-Zi and Supplement) of the second edition of the *Encyclopaedia Medica*,<sup>4</sup> the penultimate volume of which we reviewed a few months ago (October 11th, 1924, p. 670). Of the principal articles three are new—those on vitamins by Dr. Marshall Findlay, on the modern treatment of diabetes by Dr. C. G. Lambie, and on respiration by Dr. H. Whitridge Davies. The last two form a supplement to the volume. Twenty-two articles have been rewritten. The article on the uterus, which is the longest in the volume, consists of five parts, three of which have been rewritten—those on displacements by Mr. G. S. Davidson, on non-malignant tumours by Mrs. Scharlieb and Dr. Louisa Martindale, and on malignant tumours by Dr. Comyns Berkeley. The principal articles on general medical pathology changes in the urine by Dr. C. G. Lambie, visceral pain by the late Sir John F. Broadbent, therapy by Dr. W. H. Wynn. The chief articles dealing with surgery are those by Sir D'Arcy Power on the urethra and venereal diseases, by Mr. J. T. J. Morrison on wounds, and by Mr. R. C. Alexander on diseases and injuries of the wrist-joint. Public health is represented by articles on ventilation and warming by Sir Leslie Mackenzie, on vital statistics by Dr. W. Robertson, and on water by Dr. J. C. Thresh. Among the miscellaneous subjects we may call attention to the excellent articles by Dr. T. B. Hyslop on unconsciousness, by Dr. Robert Knox on x rays and radium, and by Dr. H. M. Traquair on the field of vision. We offer our cordial congratulations to Dr. ALEXANDER GOODALL and his able band of contributors on having successfully terminated a work which is admirably representative of British medicine.

<sup>3</sup> *Chemotherapy of Tuberculosis*. By Holger Moellgaard, Professor of Physiology; Physician, Royal Veterinary and Agricultural College, Copenhagen. Copenhagen: Arnold Busck, 1924. (64 x 94, pp. 419; illustrated.)

<sup>4</sup> *Encyclopaedia Medica*, Vol. XIII. Edited by Alexander Goodall, M.D., F.R.C.P.E. Second edition. Edinburgh: W. Green and Son, Ltd. 1925. (Roy. 8vo, pp. vii + 671; illustrated. 30s. net.)

## NOTES ON BOOKS.

A SHORT time ago we published a note calling attention to the field which exists for medical women in India. The same point is made in a chapter on the healing art in India in an interesting little work by Mr. H. HARCOURT, I.C.S., now on the retired list.<sup>1</sup> He believes that, whatever happens to the Government of India, no political change will ever oust Western medicine and especially Western surgery. The situation of the parda lady in sickness is pathetically helpless. Missionary women doctors and Government women doctors are an urgent need, the supply inadequate; in India it is difficult to train women in medicine for the want of a good general education on which to build. The prospect, Mr. Harcourt holds, is ample for an indefinite number of years. "Whoever else may be repulsed, the lady doctor, and hardly less the trained nurse, are still, and long will be, welcome in India." In these days, when lament is being made of the great numbers of applicants for posts for medical women in this country, at least the more enterprising of recent graduates will surely give some consideration to the sphere of useful work which is open to them in India.

The first volume of the seventh edition of Professor H. OPPENHEIM's textbook of nervous diseases for practitioners and students<sup>2</sup> has been issued; the last edition was reviewed in the year before the war (JOURNAL, August 2nd, 1913, p. 243). The author died in May, 1919, and the present edition has been revised by four well known neurologists: R. Cassirer of Berlin, K. Goldstein of Frankfurt, M. Nonne of Hamburg, and B. Pfeifer of Halle. The bulk of the present volume has been revised by Dr. Cassirer, who is responsible for the chapters on the methods of examination and general symptomatology, diffuse diseases of the spinal cord, peripheral paralysis of the spinal nerves, and nerve tumours. Dr. Pfeifer is responsible for the chapters on systemic diseases of the spinal cord, peripheral paralysis of the cerebral nerves, multiple neuritis and neuralgias; and Dr. Goldstein for the section on the pathology and physiology of the spinal cord. The principal new features of the present edition are the descriptions of war injuries, epidemic encephalitis, extrapyramidal diseases, and the close association between endocrine disturbance and nervous disorders. To judge by this first volume the work has been well brought up to date and will continue to hold its place among the leading textbooks on nervous disorders.

To those whose knowledge of tobacco literature has hitherto consisted of the mistaken idea that Raleigh introduced "the weed" to England, of Calverley's "Ode," and of Kipling's lines "A woman is only a woman, but a good cigar is a smoke," WILFRED PARTINGTON'S *Smoke Rings and Roundelays*<sup>3</sup> will come as a boon and a blessing. For here we learn much in pleasant guise. The introduction of tobacco to Europe, for example, is a feather in the cap of medicine, and lies to the credit of a Spanish physician, by name Francesco Hernandez, who brought samples of the weed from Mexico for the inspection of His Most Catholic Majesty Philip II. About the same time—*circa* 1560—Jean Nicot (whose name is still enshrined in "nicotine"), master of the requests of the French king's household and ambassador to the Portuguese court, purchased at Lisbon some tobacco seed imported from Florida. This he sent to the Grand Prior of France; and, "chiefly by the aid of members of the Chancery," the habit of smoking was propagated. Even yet it may safely be asserted that the doctor and the parson are the greatest devotees of the weed; though some there be in both professions—and these, heavy-minded men—who would rather *Nicotiana* on Old Nick. But the majority of the great pipe band will welcome *Smoke Rings and Roundelays* with avidity as a very mine in prose and verse of all that has been written regarding tobacco. Nay, that curiously white-elephantine article of furniture—beloved of a woman as a gift, in the vain hope that it may lead to tidiness—the "smoker's cabinet" need no longer hang useless on the wall if employed as a handy barbour for this volume; and the tired man, in slippers and ease and pipe in mouth, may well double his restful pleasure by pulling it out and perusing its pages.

Messrs. George Philip and Son have republished their well known *Life-size Anatomical Model*.<sup>4</sup> It consists of a signor of the human body lithographed in natural colours on linen card-board, and opening out in sections to display the blood vessels, nerves, muscles, internal organs, and the skeleton in their correct positions and dimensions. A handbook, supplied with the model, contains a numbered list of the different structures illustrated. The model folds into a stout millboard portfolio measuring 22 by 33 inches, and its portability, as well as the excellence of its general construction, should render it very useful to teachers of anatomy.

We have received the *Proceedings of the Pathological Society of Philadelphia*<sup>5</sup> from January, 1923, to January, 1924. In addition to numerous short clinical notes the volume contains the address of Dr. O. H. Perry Pepper, the retiring president, on metastasis.

<sup>1</sup> *Philip's Life-size Anatomical Model of the Human Body*. London: G. Philip and Son, Ltd. 1925. (Portfolio cover, 22 in. by 33 in. £3 3s. net.)

<sup>2</sup> *Proceedings of the Pathological Society of Philadelphia*. Edited by Baldwin Lucke, M.D. New Series, vol. xxvi; Old Series, vol. xlii. Philadelphia, 1924. (Med. 8vo, pp. 122.)

## PREPARATIONS AND APPLIANCES.

## An Aspirator.

Dr. DANIEL McLELLAN (Vancouver, B.C.) has forwarded a description of an apparatus designed by him for aspirating body fluids.

A 30 c.c.m. Luer syringe is connected by an adapter and rubber tube to the stem of a Y-shaped glass tube. A Luer aspirating needle is connected by an adapter and rubber tubing to the receiving arm of the Y-tube, and to the discharging arm is attached a longer section of tubing. Between the needle and the receiving arm a glass valve is inserted, and between the discharging arm and the exit end of the long discharging rubber tube is a similar valve. As the piston is drawn up the valve in the receiving arm opens, allowing fluid to be drawn up into the syringe, and as the piston is pushed down the valve closes, preventing the passage of fluid backwards through the needle. As the piston is pushed down the valve in the discharging arm opens, allowing the passage of fluid through the valve and out at the exit end of the long rubber tube, and as the piston is drawn up the valve closes, preventing fluid from being drawn backwards through the discharging arm. These valves (A, A), which are of

ground glass accurately fitted, are cone-shaped. The apex of the cone in the receiving arm should point towards the needle, while in the discharging arm the base of the cone should face the exit end of the long rubber tube.

In aspirating pleuritic fluid the procedure is as follows: The patient having been prepared, fill the apparatus with normal saline solution so as to expel the air. This is done by placing the needle in a bowl of saline or sterile water and taking a few strokes of the syringe. The last bubble may be expelled by inverting the syringe. A clamp (B) is then placed on the long tube to prevent the fluid running off. The exit end of the long tube must not be left standing open; it should have an adapter (C) of the same calibre as that in the receiving end. The needle being inserted into the chest, and everything ready, remove the clamp and proceed by easy steady strokes to evacuate the fluid. To ascertain beforehand that the needle is actually in the fluid, connect the syringe direct with the needle, draw up a small quantity of fluid, thus proving the point, then connect up with the apparatus and proceed.

This apparatus is intended for fluid, not for pus. It was demonstrated on a patient at the November (1924) meeting of the Vancouver Medical Association, and is in use in the Vancouver General Hospital and at the Rotary Clinic for Chest Diseases, Vancouver.

## Vulpro Waterproof Sheeting.

Vulpro waterproof sheeting is a substitute for ordinary rubber sheeting for and can be sterilized. It is said to be moist and seems very suitable for surgical operations, for fomentations, and for any purpose for which jaconet is commonly used.

# THE SAFETY OF GAS FIRES IN REGARD TO CARBON MONOXIDE.

BY  
LEONARD HILL, M.B., F.R.S.,

AND T. C. ANGUS, D.F.C.

(From the Department of Applied Physiology, National Institute for Medical Research.)

At times alarm has been expressed in connexion with the use of gas fires as to the probability of chronic poisoning arising from inhalation of carbon monoxide. In a pamphlet published recently by a medical officer of health of a large city, and circulated at the recent Smoke Abatement Conference, this view was put forward definitely, but without supporting evidence.

We thought it worth while, then, to carry out a few experiments to see whether we could put this fear at rest and remove any antagonism against the wider use of smokeless fuel which is necessary in order to secure freedom from smoke pollution of the air and an adequate supply of the health-giving ultra-violet rays. Carbon monoxide has no poisonous effect other than that of combining with haemoglobin and depriving the tissues of oxygen. Blood taken and diluted to 1 in 200 parts of distilled water afforded a standard transparent solution of haemoglobin: when placed in the narrow test tube of the Gowers-Haldane haemoglobinometer and viewed against a white background by daylight, it appeared yellow-red as is characteristic for this dilution and width of containing tube. Saturated with carbon monoxide by shaking with coal gas the tint of the solution under the same conditions is carmine. Partial saturations vary from the yellow-red very slightly tinted with pink up to the full carmine colour.

**Experiment 1.**  
A balloon was filled with a measured volume of air by means of a blower fan and meter, and enough coal gas introduced to give 1 in 1,000 parts of air. A sufficiency of the standard solution of haemoglobin was placed in a tube 6 inches long and 1 inch in diameter, which at each end was closed by a cork through which a narrow tube was inserted. The tube was held horizontally so that the solution of haemoglobin lay from end to end along its floor exposed in a shallow layer to air above which was drawn through the tube in a steady stream through the narrow tubes, one of which was connected to the balloon, while the other was suitably attached to a suction fan driven by an electric motor. During half an hour 670 litres of air from the balloon was drawn over the haemoglobin solution. On comparison with the control solution (kept in pure air) this solution gave a just perceptible change in tint, indicating a very slight formation of carbon monoxide haemoglobin.

**Experiment 2.**  
Two parts of coal gas per 1,000 of air were then put into the balloon and the experiment repeated. After thirty minutes a slight but quite definite carmine tint was clearly seen on comparison with the control.

**Experiment 3.**  
The experiment was now arranged so that air was drawn from the neighbourhood of a gas fire, a position being chosen where the person's face would be who sat down by the side of a fire in order to warm his legs. The gas fire 12 inches wide was of the modern type and properly flued, being built into a chimney, and was turned full on. During one hour 760 litres of air was drawn over the standard haemoglobin solution. No perceptible change in tint resulted.

**Experiment 4.**  
The solution was reintroduced and the experiment continued for another eighty minutes. No change in tint resulted after 1,304 litres in all had been drawn over the blood. A resting man breathes on the average about 6 to 7 litres of air a minute, or the above amount in a little over three hours. More air was then drawn over in the two hours and twenty minutes' observation than a man would breathe.

**Experiment 5.**  
An experiment was arranged so that air, in place of being drawn over, bubbled through the standard haemoglobin solution contained in a flask. In this case the rate of ventilation was about 150 litres an hour. The air was drawn from the neighbourhood of another gas fire in a different room, but of similar type and properly flued. No indication of carbon monoxide escaping into the room was found in this case.

**Experiment 6.**  
This experiment was repeated on a windy day when possibly there might be some down draught in the flue. No evidence of carbon monoxide was obtained.

**Experiment 7.**  
The experiment was repeated on a gas fire arranged in the grate of an ordinary open fireplace, the flues from the fire escaping up the open chimney above the fire. No evidence of carbon monoxide escaping into the room was obtained.

## SAFETY OF GAS FIRES.

[THE BRITISH MEDICAL JOURNAL]

**Experiment 7.**  
The experiment was repeated with this variation, that a door adjoining the gas fire was set open to create a draught between door and window across the neighbourhood of the fire. The result was negative.

**Experiment 8.**  
The experiment was repeated and varied by placing a small electric fan to blow across the gas fire to where the inlet to the sample tube lay. The fan blew across the warmed strata of air which lay in front of the fire, and this warm air was perceptible to the face when placed near the inlet tube and gave one at once a stuffy feeling. No evidence of carbon monoxide escaping into the room was found even in this extreme condition of artificial draught, which might be expected to blow fumes into the air.

**Experiment 9.**  
To make the conditions as severe as possible, four *flueless* gas stoves of various types were placed in a small room about 12,000 cubic feet in capacity, and the door and window about The stoves were lit and a mouse placed on the table in the room. After two hours the temperature of the air at head level was 100° F. dry bulb, and 87° F. wet bulb, and the room on entrance felt at once stuffy. The mouse's blood showed 16½ per cent. of carbon monoxide haemoglobin.

The difference between inside and outside temperatures set up enough natural ventilation through the crannies of door, window, and up the chimney to prevent very serious contamination of the air with carbon monoxide in this extreme case, showing how small is the amount of this gas arising from Bunsen flames burning in modern gas fires. The touch of heated air to the face on entering such a room is unpleasant, while the breathing of the heated air, which contains traces of sulphur acids, congests the nose and gives a stuffy feeling. At the same time cold feet may arise from the draught, cool air entering beneath the door. Gas fires should, then, always be properly flued. No *flueless* gas burners or stoves should, of course, be used in *sealed-up* places where natural ventilation is almost nil. In such sealed-up places carbon monoxide may collect in dangerous amounts if cold surfaces are brought in contact with Bunsen gas flames so as to check combustion.

## ROYAL COMMISSION ON LUNACY AND MENTAL DISORDER.

EVIDENCE OF THE MENTAL HOSPITALS ASSOCIATION.  
On March 10th evidence was tendered to the Commission on behalf of the Mental Hospitals Association by Alderman J. G. Taggart, J.P., of Liverpool, and Alderman Sir William Hodgson, J.P., of Crewe.

Alderman Taggart said that his association desired to eliminate the pauperization element which at present entered into lunacy administration. Were it not for their illness, less than 5 per cent. of the persons afflicted with mental disorder would be pauperized. He urged that instead of sending cases of incipient insanity to a Poor Law institution, it ought to be possible to admit them to hospitals supported by the public health authority, in the same way as fever cases and cases of tuberculosis were admitted. Mental ailments should be dealt with as one of the classes of disorders for which public health authorities had to make provision in the same way as for tuberculosis or for the treatment of venereal diseases. He was sanguine that this would prevent a very large number of persons from going on to the asylum. Such clinics would be clearing houses, relieving the asylum population, and would receive out-patients as well as in-patients. In Liverpool he thought this provision could be made with very little extension of existing accommodation at the hospitals which were provided wholly or partly by the public authority, and, indeed, a scheme might be worked out for the whole of Lancashire, and perhaps for a group of counties. In each county—or, in the more sparsely populated parts of the country, each group of counties—there should be a central clinic to which the patient might be brought. Choices at present under the control of the public health authorities were supported by grants from the State up to 50 per cent. the remainder being supplied by local taxation, and he took it that the grant would be made for mental clinics as well. In Lancashire 11 per cent. of the entire population of asylums was discharged annually, but of the cases admitted during a year 33 per cent. were discharged within twelve months of admission. He would have a modified form of provisional order, similar to that required for notification and removal in the case of infectious diseases. The witness caused some amusement by insisting on minimizing, although himself a justice, the value of the judicial functions in relation to insanity; he declared that the medical authority must be the governing one. He also put forward his views with regard to discharges. At present it was possible for three members of the visiting committee to discharge a patient even without the medical superintendent's consent. In Liverpool this arrangement had worked disastrously in one instance, where ten patients were discharged in this way by three members new to asylum work,

and most of the ten found their way back. The medical superintendent's view should not be overridden in this fashion, and any decision to discharge a patient otherwise than with the medical superintendent's concurrence should be on the responsibility of the whole committee.

Sir William Hodgson said that he approved of the general principle embodied in the Mental Treatment Bill, and the Mental Hospitals Association had passed resolutions to that effect. He wanted to fill up the gap in the treatment of mental disorder by some such scheme as was embodied in that measure, but he disagreed with some of the machinery and methods proposed, notably with the clause dealing with the constitution of visiting committees and the provision for co-option. Visiting committees should be strictly representative of elected bodies. He expressed himself generally in antagonism to the principle of co-option on public bodies. The witness was asked for his views as to the prosecution of research at asylums; the line he took was that the impetus for research among workers in asylum laboratories ought not to be smothered by interference from the Board of Control or other central authority. The inventive and discovering mind was of a peculiar type, and was not necessarily revealed in team work. Asylums with well equipped laboratories should be given a free hand in their researches. The Chairman pointed out that the requirement of approval by a central body would prevent unnecessary duplication of research and undesirable overlapping. Sir Humphry Rolleston asked whether the Board of Control had exercised any action which was detrimental to research, and the witness replied in the negative, saying that the Board had not the power; and in reply to a further question from Sir H. Rolleston, he said that he did not think it was an advantage to have the advice of the Board of Control; his association was not in favour of State grants if it would mean more control by the Board. The Chairman pointed out that the Board of Control had to deal, not only with large up-to-date laboratories and asylums, but with places where there was less zeal. Sir H. Rolleston asked whether the witness thought that the Board of Control should be dispensed with, and Sir W. Hodgson replied that he did not think that anything he had said called for that question, but he was of opinion that the Board was not doing very effective work, and he would not be sorry to see it "scrapped." The Chairman asked whether, if the Board of Control were "scrapped," it would not be necessary for some other body to be substituted. The witness replied that he thought committees elected and appointed by the people, and in direct touch with the people, would afford the best system of control. He agreed that there should be central bodies to direct and diffuse information, but not to control.

The Commission adjourned its public sittings for, we understand, some weeks. It has still much evidence to hear in public, as well as evidence tendered by the National Society for Lunacy Reform, which, dealing with specific charges against asylum administration, is to be heard in private.

### THE HOUSING PROBLEM.

THE National Housing and Town Planning Council has now issued its Technical Committee's first report, which will be read with interest by all who are specially occupied with questions of housing. The committee includes "architects, surveyors, building trade employers, building trade operatives, members and officers of local authorities, and housing reformers generally." Nearly all these classes are engaged in one capacity or another with the erection of houses, and are therefore possessed of technical knowledge. Occupants of houses, whose interests are the most important of all, are not technicians, but their case would doubtless be borne in mind, especially by local authority members who served on the committee. The subjects reported on are briefly: standards of design and construction, new methods of construction, labour supply, production of building materials, and regional distribution of new houses. It is held that houses should have three bedrooms as a rule, though two may suffice for elderly and newly married people. This is excellent in principle, but many an elderly worker, male or female, or even some of the newly married, might prefer to do with a single bedroom as part of their house, and so long as the supply of houses falls far short of the demand, which seems likely to be the position for many a year to come, the provision of more than minimum accommodation is apt to result in the occupation of houses by more than one family. The question is of great practical difficulty, but there are these two sides to it.

As concerns non-traffic streets, it is wisely recommended that, though there should be at least 70 ft. between houses on opposite sides, the roadway should be limited, and much of the space occupied by front garden or grass plots.

Turning to alternative building systems and new methods

of construction, four sets of materials are considered—concrete, timber framing, steel, and asbestos, wood pulp, etc. Concrete blocks, where suitable material can be locally obtained, and granular concrete properly prepared and poured in *situ* between shutters, are well spoken of. Only three or four lines are devoted to timber-framed houses, and in that brief space attention is called to risks of fire and vermin. Those who have had experience of timber-built hospitals which have lasted for half a century in fair condition may think that this alternative hardly receives the attention it deserves.

The subject of steel-sheeted houses is treated in much detail and has evidently received much consideration. The opinions are frankly stated, and it is right they should be, even though they must be rather disappointing to the general reader who has vaguely hoped that a way out might be found in this direction. Cost is a great difficulty. Subject to the very important reservation fully emphasized by the committee, that mass production should considerably reduce the cost, it is held that in the meantime for the same accommodation the outlay will not be less for a steel than for a brick house. Indeed, comparative figures point in the other direction. A two-story brick house of over 900 superficial feet, providing three bedrooms, parlour, living room, scullery, and bathroom, is estimated to cost, including land, sewers, and roads, a total of £580, while a bungalow steel house of only 690 superficial feet, two bedrooms, living room, scullery, and bathroom, is estimated to cost (including land, etc., as above) £565, or only £15 less. The annual loss on the former house would be £15 15s. 1d., and on the latter £22 16s. 1d. That is very disconcerting, but once more the committee lays stress on the saving that would be effected by mass production.

Concerning the supply of building labour, the position is deplorably bad. Between 1901 and 1924 the total number of men in the various occupations of house construction has fallen from 828,462 to 367,030. Of bricklayers there were, at the latter date, only 57,000 (in round numbers) as against 120,000; of masons, only 22,000 as against 97,000; of carpenters and joiners, only 125,000 instead of 306,000; slaters, 5,000 instead of 16,000; plasterers, 16,000 instead of 36,000; plumbers, 34,000 instead of 76,000; and painters, 106,000 instead of 176,000. Much space is usefully given in the report to the subject of apprentices and their educational training, but meantime the facts are as above. Also, there is a shortage of brick, stone, tiles, and slates, and it is recommended that definite steps be taken by the Government and by local authorities to stimulate increased supplies.

Thus the country cries out for more houses, larger houses, and better houses. But there are not sufficient materials with which to build them, nor half enough skilled men to use the materials even if they were obtainable. At the same time more than a million men of other occupations are wandering about the streets out of employment, living on the dole, and complaining that it is not enough, while overburdened taxpayers and ratepayers declare themselves exhausted by what they are already called on to pay. The million of idle men includes thousands of shipbuilders, who now have to witness the dispatch of orders for new British ships to German makers, though shipbuilding has hitherto been the supreme example of the benefits of free trade, which enabled this country to out-distance all competitors, by buying at the lowest possible price every kind of raw material produced in any part of the world. Meantime the man in the street reads in the press suggestions that housebuilders, whether employers or employed, object to new methods of construction, as poaching on their preserves, whilst by no means enthusiastically welcoming the recruiting of their thinned ranks from the army of the unemployed. It does not lie with the medical profession to express any opinion between rival contentions, but every reasonable person must wish God-speed to the Prime Minister in his earnest endeavour to substitute for all these mad rivalries a spirit of conciliation and co-operation so as to save civilization from the destruction which at present threatens to overwhelm it. And not the least of its dangers is the failure to find means to provide reasonable housing accommodation for

those who are so urgently in need of it. The relation of housing to both moral and physical health makes the whole subject of special interest to all who are occupied with the prevention and cure of disease.

### POST-GRADUATE TEACHING IN LONDON.

A MEETING, to which all practitioners were invited, was held at the house of the Royal Society of Medicine on March 18th, under the auspices of the Fellowship of Medicine and Post-Graduate Association, to discuss the best means of developing the Fellowship and increasing its range of usefulness. Sir W. ARBUTHNOT LANE presided over an attendance of from eighty to one hundred.

The CHAIRMAN said that the Fellowship had already grown to considerable dimensions and was rapidly becoming more popular. In time it must become a most important agent for education. Post-graduate study was a habit which every medical man must acquire if he hoped to succeed in his profession and to gain the respect and confidence of the lay public. The consulting branches of the profession had recognized the great value of interchange of ideas, but medical men in general practice had to realize equally the importance of being well abreast of recent knowledge.

Mr. HERBERT PATERSON, one of the joint honorary secretaries of the Fellowship of Medicine and Post-Graduate Association, said that in America almost every doctor attended post-graduate teaching at least once a year, and the habit was one to be encouraged in this country. It was also hoped to make London a world centre of post-graduate teaching and to intercept some of the students from overseas who were intending to go on to Vienna. Since the institution of the Fellowship five years ago over £7,000 had been distributed in fees to the various hospitals. The purpose of the present meeting was to ascertain more clearly what post-graduates wanted.

#### *Post-Graduate Study in the Navy.*

Surgeon Commander T. BROWN SHAW, R.N., expressed the regret of the Director-General of the Medical Department of the Royal Navy (Surgeon Vice-Admiral Chambers) for his inability to be present. Every medical officer in the navy, when he attained eight or ten years' seniority, must pass an examination to qualify for the rank of surgeon commander. The first period of post-graduate study consisted of three months devoted to medicine and surgery at a London hospital, and two months at the Naval Hospital at Greenwich, with visits to the School of Tropical Medicine. The second period commenced when the officer had attained a seniority of fourteen years' service, the course extending for three months, and being designed to afford him an opportunity of refreshing his general knowledge and of taking up special subjects. These courses were not compulsory, but every facility was given to officers to take part in them. During the three years 1922-24 seventy-one naval medical officers attended such post-graduate courses, and it was thought probable that this number would be materially increased in the future. In arranging courses of study for senior officers the facilities afforded by the Fellowship of Medicine had proved invaluable, and the speaker's own work as Director of Medical Studies had been simplified. The requirements of the Naval Medical Service included extended courses in general medicine and surgery, and in special branches, notably neurology, psychological medicine, cardiology, dermatology, ophthalmology, diseases of the ear, nose, and throat, and operative surgery. While centralization of teaching might be considered by many a desirable objective, the facilities afforded by the Fellowship for attending different hospitals and hearing the views of different teachers were a great asset. The special courses in general medicine and surgery, lasting about two weeks, had been highly spoken of by the officers, but a little more clinical work would be appreciated in place of some of the lectures; the courses were a little too crowded, and there should be more courses in operative surgery, which at present could be arranged only with the greatest difficulty, if at all.

#### *Post-Graduate Study in the Army.*

The Director-General of the Army Medical Service, Lieut.-General Sir W. B. LEISHMAN, said that the army had not so far resorted to the Fellowship. Arrangements for post-graduate study had grown up gradually at the Royal Army Medical College, had been interrupted by the war, but had been restarted, and were now in full working order, to the profound gratitude of every officer concerned. These courses were compulsory. Officers joined the college, on the average, at about the eighth or tenth year of their service, which, in normal times, coincided with their return after their first period of foreign service, when their knowledge was naturally a little rusty. In the army it was necessary to forecast the need and the provision, and to adjust the establishment to allow of a sufficient number of officers being trained at the college at any one time. Thus, successive bodies of officers were continuously under instruction. On an average thirty captains attended the course, which was divided roughly into three parts. In the first part they went to the college and received instruction from the staff in medicine—largely tropical medicine—surgery, pathology, and State medicine. That instruction might be called internal or domestic, and it was supplemented in various directions outside—for example, by attendance at the recruiting stations. This lasted for three months, and was terminated, like every stage of the training, by an examination. In the second stage, the officers, while still in residence at the college, were detached for further study in clinical medicine and surgery, and attended by arrangement at large civil hospitals—at present Charing Cross and St. Thomas's—where they had the benefit of seeing modern practice and also of attending special tutorial classes. At the end of this period, which extended for two months, making five months in all, came another examination. The third stage went a little further. It was desired to encourage every officer who had any particular bent to obtain the fullest instruction in the branch he favoured and to qualify himself as a specialist. Not all officers could be trained as specialists, of course, for that would bring about an absurd position in the army. It was possible only to justify the provision of specialists for whom there was work, and only about 50 per cent. of those attending the general course went on to specialization. Officers were not allowed to go on to specialize unless they had attained a certain standard of efficiency in the general examinations preceding that stage. A list of eleven subjects was presented from which the officer might choose: medicine (including tropical medicine), advanced operative surgery, pathology, hygiene, ophthalmology, ear, nose, and throat diseases, obstetrics and gynaecology (a very necessary army subject), dermatology (including venereal diseases), radiology, anaesthetics, and mental diseases. The course was for four months, except in hygiene, where it was extended to six months to make it fit in with the General Medical Council's new regulations for the D.P.H. The examination in these subjects demanded a very high standard, and it was not all who succeeded. Certain of the subjects could be taught at the college as well as anywhere else, but it was realized that in the majority of cases there must be resort to various hospitals and other institutions, and this help from the civil side of the profession was greatly esteemed. The attainment of qualification meant an addition of 2s. 6d. to the daily pay, but, much more than that, it gave its possessor the opportunity of developing his professional skill on lines for which he had an inclination. An endeavour was made to encourage the men wherever possible to obtain higher degrees and technical qualifications in particular subjects—the diploma in psychological medicine, for instance. A further point was that this nine months' post-graduate education was carried out without expenso to the officer. This was because the service was a State medical service, and the State, once convinced of a good case, was not an ungenerous paymaster.

#### *The General Practitioner's Needs.*

Dr. GILBERT ORME spoke as a general practitioner who had lately settled in London after a long experience of Lancashire. He paid a tribute to the good work done by

the Fellowship, under whose auspices he had taken a three months' post-graduate course. He had met with courtesy and help in every direction; one or two complaints from others which he had heard seemed to him groundless. It was said that strangers coming to London were at a loss to know where to attend, and that when they went to certain hospitals nobody took any notice of them. If these persons studied the monthly syllabus issued by the Fellowship they would have no occasion for complaint. He suggested, however, that certain consultants or junior members of staffs of hospitals should be asked to allow their names to be placed on a panel, and that as part of their work they should arrange "personally conducted tours" round certain hospitals, which he supposed must be hospitals not having medical schools. It was not out-of-the-way and mysterious cases which would be taken, but such cases as might be met with in general practice from day to day. There should be a close relation between the central post-graduate body in London and post-graduate schools existing in the provinces. It was conceivable that men from the colonies or abroad might wish to take part of their course in London and spend the rest of it at some medical school in the provinces or in Scotland. The officials of the Fellowship should try to arrange for parties to be made up in London to go abroad to various foreign schools. This method, widely adopted in America, would be of interest and value to those practitioners who wanted to learn foreign methods, and would also bring before Continental schools the work that the Fellowship of Medicine was doing in England.

Mr. ZACHARY COPE thought that many would feel, after the explanation of the way in which officers in the navy and army had their needs met, that some national scheme ought to be set up whereby civil practitioners who felt the need of a "refresher" course could have adequate opportunity for taking it. Such a scheme should embrace the whole country, and co-ordinate London and provincial post-graduate courses. Sir William Leishman had stated that the State was not ungenerous. If that was so, the complaint of civil practitioners that they could not afford post-graduate courses ought to be met by some form of subsidy. While he would not suggest that the courses, compulsory in the army and navy, should be compulsory in the civil profession, he thought the Fellowship might try to get some official endorsement for a plan whereby civil practitioners would not only be given the opportunity but would be actually induced to improve their medicine for the good of the community as a whole.

Dr. MURIEL LANE asked for more obstetric and gynaecological courses, to which might be added some ante-natal and post-natal work. It would be useful, in the study of preventive medicine, if some children's welfare centres were added to the list of places attended. She also mentioned the paucity of clinical material on the woman's side in venereal diseases.

Dr. SOPHIA JEVONS reminded those present of the excellence of the Polyclinic of the old days, and thought that something on the same plan might be adopted by the Fellowship—that is to say, lectures, with or without cases, at a certain hour every afternoon four or five days a week. This would be better than intensive courses which the practitioner had to give up his work to attend.

#### *Criticisms of Post-Graduate Teaching.*

Dr. H. B. NEWHAM said that he had been connected with post-graduate teaching for the last seventeen or eighteen years at the London School of Tropical Medicine, and 2,000 students from all parts of the world had passed through his hands. He had heard from them many criticisms of post-graduate teaching in London, but he had no complaint to bring forward against the Fellowship. His complaint was rather against those actually engaged in the work of instruction, that they did not take a greater interest in the art of teaching. London had first-class physicians and surgeons, but frequently they had no flair for teaching and were not inclined to try. In London—unlike Scotland—men were appointed to the staffs of hospitals without any regard to their teaching capacity. Again, many people who came for post-graduate instruction

did so at considerable inconvenience to themselves; probably they desired, say on two days a week, to go round with one particular physician attached to a hospital. He recalled that, before the days of the Fellowship, he once paid a fee for a course of instruction, and wanted to go round with a physician in charge of in-patients. He attended the hospital five times, and on three of those occasions this physician did not turn up, and there was nobody present to take his place. Another criticism was that there was too much tendency to have lectures on "curiosities"; what the average practitioner desired as a "refresher" was to see the cases he was likely to meet with in general practice, not the rare cases he might scarcely see in a lifetime.

#### *A Plea for a Post-Graduate School of Medicine.*

Dr. M. B. RAY said that a glance at the *Bulletin* would show that facilities for post-graduate instruction existed at practically every hospital in London, so there could be no complaint as to lack of material, nor, indeed, the quality of the instruction. It remained only to inquire into the organization. Those seeking post-graduate instruction might be divided into two classes. There were, first, those resident in London or its neighbourhood who occupied their spare time in sporadic attendances at various hospitals, occasionally taking up intensive courses; together with these were visitors from abroad who combined sight-seeing with a certain amount of post-graduate study. The needs of all these casual post-graduate students were admirably met by the existing arrangements. The second class was much more important, or at least its potentialities were greater. It included all who desired to spend from four to six months in earnest study. The idea might be Utopian, but it would be a great advantage if after a given time in practice all medical men were compelled to take up "refresher" courses. It was extremely difficult to run a practice and at the same time be *au courant* with the progress of medical learning. Such practitioners might at the present time enter into the same sort of arrangements as the casual post-graduate student, but the result was usually mental dyspepsia and fatigue; or they might go back to their old school and take up what they could in the way of instruction, but, as the school was intended for young men, this might prove irksome. Dr. Ray favoured the establishment of an up-to-date thoroughly equipped post-graduate school of medicine, devised to meet the needs of general practitioners, with a teaching staff devoting their entire energies to this work. The school and hospital to which it was attached should be definitely known by a distinctive title implying post-graduate work. The course of study should be sufficiently long to ensure adequate teaching. At the end of each course an examination should be held entitling the successful entrants to a diploma so that they would be able to style themselves graduates of the post-graduate school or some such title. At first the only men to come forward would be those in a position to delegate their practices to others, but as the fame of the school extended more and more men would flock to it. As matters stood, wonderful clinical material and unrivalled teaching were running to waste for lack of adequate direction.

Dr. FORTESCUE FOX said that one unfortunate circumstance that attended the amalgamation of societies in the Royal Society of Medicine was the forfeiture of the right of sections to promote post-graduate teaching in their own subjects. He urged the value of post-graduate teaching in balneology, and climatology, in which probably five hundred members of the profession in this country were specially interested.

Mr. E. B. TURNER spoke of the desirability that practitioners should take part in public health work. This would be first-rate post-graduate work, and would help to avert the tendency for public health work to get solely into the hands of whole-time officers.

#### *Adjournment.*

On the motion of Sir THOMAS HORDER, seconded by Sir HOLBURN WARING, the discussion was adjourned to Wednesday, April 8th, at 6 p.m.

# MEMORIAL TO SIR WILLIAM MACEWEN.

The committee appointed to arrange for a suitable memorial to the late Sir William Macewen, Regius Professor of Surgery in the University of Glasgow, has prepared a first list of subscriptions, which is printed below. The proposal is, as we have already announced, that the fund should be applied to three main purposes: (1) The provision of a bust to be presented to the University and a replica for Lady Macewen. The making of the bust has been entrusted to Mr. G. H. Paulin, A.R.S.A., and it is hoped that both bust and replica may be completed during the course of this year. (2) The endowment of a Macewen memorial lectureship, to deal with some surgical subject, and to be given annually or biennially. (3) The foundation of a Macewen medal or prize in surgery, to be awarded annually. To achieve all these three objects the committee finds that £3,000 will be required; the amount so far obtained (£1,550) is a little more than half that desired. We feel sure that there will be no difficulty in obtaining the remainder, and that in particular members of the British Medical Association will be ready to contribute. The Annual Meeting of the Association at Glasgow, over which Sir William Macewen presided, was a great success, and in many other ways he showed his deep interest in the welfare of the Association, not only at home, but overseas. Among other evidences of this was the visit he paid to Australia in 1923, and the welcome he received there was very grateful to members in this country. Sir William Macewen's reputation was world-wide, and it will be seen that among the subscribers in the list published below are some foreign surgeons of great distinction, including Professor Harvey Cushing of Boston, Professor Rosing of Copenhagen, Professor Hartmann of Paris, Rome, Dr. George W. Crile of Cleveland, and Professor de Quervain of Berne. The chairman of the executive committee in Glasgow is Dr. Archibald Young; the honorary secretary is Professor Archibald Young; the honorary treasurer is Professor Archibald Young; the is Mr. James Macfarlane, D.L., LL.D., Wesleyan Street, Glasgow, S.E.

## FIRST LIST OF SUBSCRIPTIONS.

- £110.—H.R.H. Princess Louise, Duchess of Argyll.
- £100.—Dr. James W. Allan (Peebles), Bailie David McCowan (Glasgow), Mr. James Macfarlane, LL.D., J.P. (Glasgow), Sir John Reid (Glasgow), (Troon), Mr. Robert H. Parry (Boar's Hill, near Oxford).
- £25.—Sir Robert MacAlpine, Bt. (Glasgow), Mr. and Mrs. George Morton LL.D. (Carlisle), Mr. J. Hogarth Pringle (Peebles).
- £21.—Mr. Leonard Gow (Glasgow), the Right Hon. Lord Newlands, George W. Macfarlane, J.P. (Glasgow), Professor Archibald Young (Glasgow).
- £10.—Mr. and Mrs. W. Martin (Core).
- £11 9s.—Dolance of Royal Infirmary Staff Memorial, per Dr. John Henderson (Glasgow).
- £10 10s.—Mr. A. H. Burgess (Manchester), the Right Hon. Lord Glenarthur (Troon), Dr. J. N. Marshall (Bolton), Professor T. K. Munro the Marquess of Bute, K.T. (Cardiff), Mr. Harold E. Yarrow (Glasgow).

## Nova et Vetera.

### NIGEL, THE PHYSICIAN OF THE DOMESDAY BOOK.

NIGELLUS, the only representative, so far as I am aware, of the medical profession mentioned in Domesday Book, is held by some to have been the Conqueror's physician, by others the physician to Earl Roger de Montgomery; both views are probably correct, for Earl Roger was the Conqueror's near kinsman. Contemporary records in which to search are not numerous; they consist of Domesday Book and the various charters to religious houses in England and France which were expedited by William. While I do not pretend to have read every charter in the eight folio volumes of Dugdale's *Monasticon*, I have looked through those of the Conqueror, and I do not find that the physician witnessed any of them; for the most part they are witnessed by great ecclesiastical dignitaries and the great feudal nobles of the realm, and if Nigel acted as a witness to any of them he must have been included in the "*multis aliis*" with which the attesting clauses usually end. In passing, I may state that it is very rare to find a medical witness in any of these early charters; I only noticed three, and they were all of a date much after that of the Domesday survey.

Domesday tells us the names and details of the estates which were conferred on Nigel. They are scattered over half a dozen counties, but for the most part occurred in Shropshire, Hereford, Wilts, Somerset, and Devon. In most instances, save, I believe, in the Exon Domesday, where he is named Presbyter, Nigel is styled Medicus. He was probably a priest-physician; at this date he can have been only a priest or a quack, and my respect for the Conqueror will not allow me to think that he can have been so easily gulled as to have admitted a quack as his physician.

One extract from Domesday will suffice for all, and I therefore transcribe the record of Nigel's Shropshire holding. In this county he finds himself in distinguished company. The tenants in *capite* in the county consisted of two bishops (Chester and Hereford), the Church of St. Remigius, Earl Roger with his men, Osbert FitzRichard, Ralph de Mortemer, Roger de Lacy, Hugh L'Ane, and Nigel the Physician. The extract is as follows:

#### TERRA NIGELLI MEDICI. IN LENTEURDE HUNDREDO.

Nigellus Medicus tenet de Rege WISTANSTOW. Spirtes presbyter tenuit de S. ALMUND. et erat T.R.E. victus canonicorum. Ibi iiii hidae. Terra est xv carucarum. Ibi vii villani cum vii carucis, et unus Francigena habens molinum quod reddit v summas annonae. T.R.E. valebat xxx solidos; modo xx solidos. Wastam invenit. Idem Nigellus tenet CLEU. Spirtes tenuit. Ibi i hida geldabilis. Terra est iiii carucarum. In dominio est dimidia caruca, et unus servus, et unus radman, et iiii bordarii cum i caruca. T.R.E. valebat xii solidos; modo x solidos. Wastam invenit.

#### Translation.

Nigellus the physician holds of the King WISTANSTOW. Spirtes the priest held it of St. Alkmund, and it was in the time of King Jf. I. a victual of the canons. There are 4 hides. It is a post-graduate teaching place. There are 7 villas with 7 ox-teams, and one year at the London School of Trade of corn. In the time 2,000 students from all parts of the land found it waste through his hands. He had heard. In the demesne is criticism of post-graduate teaching in London, and 4 bordarii no complaint to bring forward against them, it was worth His complaint was rather against those actual, in the work of instruction, that they did not take 16s. interest in the art of teaching. London had in the physicians and surgeons, but frequently they had let that for teaching and were not inclined to try. In London unlike Scotland—men were appointed to the staffs of hospitals without any regard to their teaching capacity. Again, many people who came for post-graduate instruction

Hundred, were held at the Domesday survey by Nigellus; in none of these manors is he styled medicus. Eyton, in the *Antiquities of Shropshire* (vol. 10, p. 1), says that the Nigellus of Hodnet Hundred

"has been identified by some with Nigel de Stafford, the reputed brother of Robert, first Baron Stafford, and the undoubted ancestor of the Gresleys. I must bespeak for our Shropshire Nigel a position far inferior both in its antecedents and its consequents. He was a clerk, and a physician—physician, indeed, to Earl Roger de Montgomery himself. In seven instances he succeeded to the benefices of Spirtes, a Saxon priest. This was in his spiritual capacity. The compact estate of four manors, which he held under Earl Roger in North Shropshire, would probably have descended, as a lay-fee, to his heirs, if heirs he had. I should here observe that a lay-fee in Staffordshire, consisting of three manors held in *capite* of the King by Nigellus, was much more probably the fee of Nigel de Stafford than of Nigel the physician. There can be no doubt that Nigel the physician died in the time of Earl Hugh de Montgomery (1094-1098), and that his estates in Shropshire escheated to the same Earl."

and so to his brother Earl Robert de Belesme, at whose defeat by Henry I they escheated to the King.

Before leaving Nigel's Shropshire holding it is of interest to turn to his rent of 16s. from the manor of Bromfield. Domesday has, "et Nigellus Medicus habet de hoc manerio xvi solidos." In the time of King Edward, Spirtes had a large holding in this manor. Eyton (vol. 5, p. 207) tells us a good deal about Spirtes.

"He lived in the reigns of three Saxon kings, Harold I, Hardicanute, and Edward the Confessor. With the first two he was a special favourite; the last banished him, for what cause is not known. The Herefordshire Domesday refers to a period of the Confessor's reign, when Spirtes the priest held four manors in that county under the Church of St. Guthlac. At Domesday St. Guthlac had lost the seigniorship of these manors, and the same Nigel the physician, who had an interest in Bromfield, held them in the Church. Spirtes was a canon of the Church of Alkmund, Shrewsbury. His prebend was both the Church and the Manor. A monastic memorial of great credibility tells us nothing of Spirtes's previous banishment, but begins with the fact of Edward the Confessor bestowing the prebend of Wistanstow on Godric Wifesunc, on whose death, says the same record, Earl Roger gave the prebend to Nigel, a clerk, his own physician. (Lilleshall Charters, fo. 100.) Domesday, in all but perfect harmony, gives Nigel the physician as Lord of Wistanstow, but holding it of the King, not of Earl Roger."

It will have been observed that under Bromfield, Nigel is expressly called Medicus, and that in the case of the four manors in the north of the county he is not so styled. It must be remembered that the primo object of the Domesday survey was fiscal. It was a territorial record enumerating those who held the land in 1085; by whom it was held in the Confessor's reign; how much there was of it; how many plough-teams, serfs, villains, radmen, bordarii, etc.; what it was worth at the survey, and how much it was worth before the Conquest. With Domesday at hand the King could settle disputes of succession, and he could also get a shrewd idea as to the amount of taxation the country would stand. Now it was immaterial from the revenue point of view whether Nigel was called Medicus or not. A King's writ would have reached him in Hodnet or in any of his other holdings as easily as the G.P.O. delivers us our income-tax forms at the present day, allowing for the difficulties of transport at that early date; but I cannot see why the commissioners should have called Nigel Medicus in one place and not in another in the same county. Far be it from me to question the accuracy of, or to appear to sit in judgement on, the late Rev. R. W. Eyton, the historian of my native county and one of the greatest genealogists and experts on Domesday that has ever lived. I simply state the difficulty as it appears to me. The only difference in the two holdings was that in the south of the county Nigel held direct from the King, and in the north from the Norman earl, Roger. We have seen that Nigel succeeded Spirtes in Shropshire and Hereford; the same was the case in Wilts and Somerset. I do not give the extracts from Domesday as I do not wish to be accused of prolixity; but in the four manors in Wilts Nigel succeeded Spirtes and was a tenant in *capite* of the Crown.

Here let us leave him, surrounded by his serfs, his villains, his radmen, and bordarii, and his 16s. from St. Mary's, Bromfield, until the Judgement Day.

R. R. JAMES, F.R.C.S.

## CARCINOMA OF THE CERVIX.

Two main difficulties are encountered in investigating the incidence and response to treatment of carcinoma of the cervix uteri. The first is that of constructing some system of classification applicable to a large series of cases so that statistical deductions may be soundly based. The second difficulty is that of assessing the value of different remedies in a disease in which the criteria of the effectiveness of treatment are so uncertain at present that the adjective "cured" is usually replaced by the more cautious term "arrested." This problem of the incidence of carcinoma of the cervix, and of its response to radium therapy, alone or combined with x-ray treatment, has been attacked during the last few years by several investigators, both in this country and in the United States of America, and statistical reports are increasing in number.

Two recent American reports call for special attention. H. Schmitz<sup>1</sup> has published an account of 450 cases treated in his clinic between 1914 and 1923; and H. C. Taylor and T. C. Peightal<sup>2</sup> describe their investigation of 201 cases observed between 1910 and 1921. Of the 450 patients of Schmitz 345 had primary carcinoma, while in 104 recurrence of the disease had followed pan-hysterectomy. Schmitz points out the disadvantage of grouping cases according to the uncertain criterion of operability, into which the complicating personal factor of both the patient and the surgeon enters. He prefers the four following groups, based on the results of general and bimanual physical examination, together with endoscopic examination of the bladder and rectum. Group 1 contains the cases in which the cancer is clearly limited to the cervix, and Group 2 the doubtful cases in which there is some evidence of infiltration of the paracervical connective tissue; in Group 3 he places cases in which there is induration of the contiguous tissues and advanced disease, with large areas of necrosis, toxæmic cachexia, and metastases. He first tabulates his 450 cases according to the calendar year and the years 1914 to 1917 there was no appreciable change in the number of cases dealt with in any of the four groups, from 1918 onwards there was a marked and progressive increase in both primary and recurrent cases.

Schmitz agrees with Taylor and Peightal with regard to the age incidence of this disease. Of Schmitz's cases 84 per cent. occurred between the 30th and the 60th years, the Taylor and Peightal figures giving 90 per cent. Between the ages of 40 and 60 the Schmitz percentage is 67, as compared with 70 of the two other authors. The relation of cancer incidence to past pregnancies is considered in both papers, and Schmitz, in common with Taylor and Peightal, opposes the prevalent view that the occur-

rence of carcinoma of the cervix is related to multiple pregnancies. Schmitz considers the deduction permissible that chronic infections resulting from trauma and bacterial invasion predispose primarily to cancer, and that the number of pregnancies is only a possible secondary predisposing factor. In a total of 400 consecutive cancer cases he found that 241 patients (60.25 per cent.) had three or fewer pregnancies or were childless. Recognizing that it might be suggested that marriages resulting in from none to three children predominated in American families, he tabulated 400 case-histories of healthy married women, aged 41 or older, according to the number of children. He thus found that the percentage of the number of pregnancies was practically the same as in the case of cancerous patients. Schmitz found that in 406 case-histories the most prominent symptom which induced the patient to seek medical aid was definitely stated to be hæmorrhage in 249 cases (61.5 per cent.); pain in 82 cases (21.1 per cent.); and vaginal discharge in 60 cases (or 14.7 per cent.). He concludes that hæmorrhage of less than three months' duration probably indicates that the patient belongs to Group 1; if pain was the most prominent symptom the patient might be referable to any of the other three groups; while discharge as the most prominent symptom gave very little information as to the extent of the disease. He adds that hæmorrhage is the most alarming symptom; discharge the first to appear; and pain the most unfavourable symptom of carcinoma of the cervix. Patients in Group 4 (advanced cases) always presented the three symptoms.

With regard to the results of different methods of treatment, Schmitz agrees with Taylor and Peightal that radium therapy gives better results in the inoperable cases of Group 4 than are obtainable by any other non-operative palliative procedure or by cautery. In early cases Taylor and Peightal assert definitely that the hysterectomy statistics compare very favourably with those of radium treatment: Schmitz, however, takes the opposite view. Taylor and Peightal's figures for early cases treated by hysterectomy gave 34 per cent. free from recurrence three years or more after the operation; 25 per cent. free five years or more. When hysterectomy was combined with radiation 44 per cent. had no recurrence three years or more after treatment, and 31 per cent. five years or more. Schmitz's clinic very few early cases (those in Groups 1 and 2) were treated; he was mostly concerned with patients in whom operation had been pronounced with advisable. Using radium combined with x rays, three patients in Group 1 were free from active disease after five years, and six in Group 2, the relative percentages being respectively 100 and 40. He also publishes a table of statistics of cases collected from six clinics. Three of these clinics made use of radium only, and three combined radium with x rays; in the latter case the percentage of cases of all groups remaining free from disease after five years was in the neighbourhood of 14 (211 patients were alive out of 1,480 treated). In Group 1, 14 out of 30 patients (44.4 per cent.) treated by radium only at two clinics were alive, as compared with 69 out of 175 (33.7 per cent.) treated by both radium and x rays at three other clinics.

Although the figures are at present too small for any final deductions to be drawn, yet the conclusion in both articles is that the combination of radium and x rays in the treatment of carcinoma of the cervix is likely to gain favour, especially in border-line or inoperable cases.

## THE INTERNATIONAL CONTROL OF DRUGS OF ADDICTION.

IN the JOURNAL of February 28th reference was made to the agreement, convention, and protocols, which were the outcome of the two prolonged opium conferences held at Geneva between November, 1924, and February, 1925. The agreement reached by the first conference, signed by Great Britain, France, India, Japan, Netherlands, Portugal, and Siam (the two last with reservations), purports to bring about the suppression of the use of opium for smoking, as enacted in Chapter II of the Hague International Opium Convention of 1912. It lays stress on the increase of smuggling as "greatly hampering" the accomplishment of this suppression. It seeks to make the traffic in opium and the manufacture of smoking opium Government monopolies (even "dross" is to be purchasable only by the monopoly), and illicit traffic is to be prohibited. These provisions will be applicable only to those territories in which the use of prepared opium is "temporarily authorized." The protocol recites that the signatories, "anxious to ensure the complete and final execution of the obligations and to strengthen the undertakings assumed under Article VI of the Hague Convention of 1912," will, "as soon as the poppy-growing countries have ensured the effective execution of the necessary measures to prevent the exportation of raw opium from their territories from constituting a serious obstacle" to reduction of opium smoking, take measures "to reduce consumption of prepared opium . . . so that such may be completely suppressed within a period of not more than fifteen years" from the time when a commission appointed by the Council of the League of Nations shall decide that such effective measures to prevent the export of raw opium have been taken.

There are not wanting critics who doubt whether experience of Government monopoly in opium elsewhere has tended to the abolition of traffic in the drug, and it is urged that the extension of the possible period for legitimate opium smoking to fifteen years from some indefinite future date is a rather disingenuous method of achieving that effective suppression or prohibition which the Hague Convention of thirteen years ago undertook to effect either "immediately" or "as soon as possible." A recent reply in the House of Commons has shown that in Brunei 18.24 per cent. and in the Straits Settlements no less than 45.4 per cent. of the Government revenue is derived from opium, and the question is being asked whether a commencement in the policy of prohibition or suppression might not be initiated in the British Crown Colonies. On March 13th in the Indian Assembly at Delhi, by 60 votes to 52, a motion was carried, against the Government, for reduction of the revenue from opium, with a view, it is alleged, of securing investigation into the opium policy of the Indian Government.

The convention, protocol, and final act of the second Geneva opium conference, directed against the traffic in manufactured narcotic drugs, in some respects repeats, in others strengthens and elaborates, and in others possibly weakens, the provisions of Chapter III of the Hague Convention. Indian hemp is added to the list of scheduled drugs; a permanent central board, with watching, advisory, and carefully limited powers, is set up, to which information as to supplies, stocks, and demands is to be furnished. "Tincture of opium, Sydenham laudanum, and Dover powder" for urgent cases may be exempted from the usual regulations up to a dose of "25 centigrams of

official opium." Up to the present time the convention, protocol, and final act have been signed by Albania, Australia, Belgium, Brazil, France, Germany, Great Britain, Greece, Japan, Luxembourg, Netherlands, Persia, Poland, Portugal, Siam, and Uruguay. Bolivia and Hungary have signed only the Final Act. The United States of America and China, it will be remembered, withdrew from the second conference shortly before its close.

### CONDUCT AND BODILY DISEASE.

SIR HUMPHRY ROLLESTON has had reprinted from the pages of the *Midland Medical Journal* an address upon some historical cases of disease and their remote effects on others which he delivered last autumn to the Midland Medical Society. The theme is one which has been touched upon by a number of writers whom Sir Humphry quotes, and it is one of perennial interest. Although it may be idle, it is nevertheless generally interesting to speculate on what would have happened had the Napoleon of 1815 been as efficient as he of the "whiff of grape-shot" twenty years earlier. Many other cases are considered in the address, and many more will suggest themselves to the thoughtful reader, whether he holds with Jeffrey and Brinkham that "the mind is independent of the body," or accepts the teaching of Mandsley and others that the mind is a function of the body. We may judge how strong and resistant is Dryden's "thin partition" in cases such as that of John Hunter, as quoted by Sir D'Arcy Power, and in many of the historical instances referred to by Sir Humphry Rolleston. Yet is the finest intellect at the mercy of a minute wandering particle of fibrin which, if it blocks the appropriate vessel, may reduce the poet, the statesman, or the man of science to second childishness and mere oblivion. Sir Humphry recalls to us the very polemic writings of the late George M. Gould of Philadelphia, who contended in six volumes of *Biographical Clinics* that every distinguished man of letters suffered from eye-strain, and that the prescription of proper spectacles would have cured him. If it were objected that some of these sufferers had the best available ophthalmological advice, it appeared further that only in Philadelphia could the correct lenses be prescribed and fitted. Others have urged that defect or excess of internal secretions has been responsible for the maladies of genius, and in this connexion it is noteworthy how little is written, probably because so little is known, of the sexual lives of great men. Sir Humphry Rolleston's address is full of suggestive information which may well prove fruitful. It furnishes corroborative evidence, if such can be needed, of the excellence of the judgement which selected him to succeed that most learned and wise physician, Sir Clifford Allbutt, in the Regius Chair of Physic at Cambridge.

### WHAT IS AN EYE SPECIALIST?

DR. FREELAND FERGUS, the veteran ophthalmic surgeon of Glasgow, has written a pamphlet in which he discusses the question set at the head of this note. It is in the form of an open letter addressed to a colleague. The epistolary form of communication lends itself to a certain degree of discursiveness, and in this letter Dr. Fergus lets himself go on more than his main topic. But the intention of his letter is plain. It is an onslaught upon the General Assembly Council for certain shortcomings he lays to its door, whether or not that Council is to blame for the "succeeded" finds in medical practice is a matter of discussion. He says: "At the moment there is no recognized, his villains, qualification; any registered practitioner in St. Mary's,

<sup>1</sup> *What is an Eye Specialist? or the General Ophthalmology.* By A. Freeland Fergus, M.D., F.R.C.S. (Edinburgh, 1924. (Pp. 31.)

inquiries before and since. Whether it is possible to do so adequately without a comprehensive reform, not only of coroners' law, but of the whole mechanism of death certification and registration, in which coroners' law plays an important part, is open to doubt. The British Medical Association has long held the wider view, and for the last eighteen months a special subcommittee has been working to adapt the policy of the Association as originally laid down between 1904 and 1909 to the existing situation. It is now recognized that the bill introduced for the Association by Major Molloy in 1923 was in several respects unsatisfactory. A bill on similar lines was introduced by Dr. Salter in 1923, and in 1924 on behalf of the Federation of Medical and Allied Services. Pending such radical reform there are several points besides those mentioned by the Home Secretary which call for immediate attention, and on the merits of which opinion can hardly be divided. The fees for medical witnesses under the Coroners Act of 1887—namely, one guinea for attendance to give evidence during the whole course of the inquiry and an additional guinea for a *post-mortem* examination carried out by a private practitioner—were inadequate in 1909, when the departmental committee sat; they are to-day little less than absurd, whilst the provision of Section 22 of the Act, whereby certain medical officers are altogether debarred from receiving fees in connexion with inquests on patients dying in the institutions they serve, is not rendered more equitable by the lapse of time. In this connexion the decision of the London County Council, on the representation of the Government auditor, that Poor Law infirmaries, hospitals controlled by the Metropolitan Asylums Board, general infirmaries, prisons, and other medical institutions of a public character can properly be included among the institutions to which this section applies, was noted in the BRITISH MEDICAL JOURNAL on August 9th last. To extend materially after so long an interval the application of a provision generally recognized as inequitable is, to say the least of it, unusual. It may be hoped that it will have the effect of focusing departmental attention upon the position to good purpose, and that the promised bill will afford the desired relief. That the coroners themselves resent the necessity for withholding fees under this provision is made amply clear by their comments from time to time when the question arises. Dr. Waldo, the City coroner, especially has never neglected an opportunity of pressing the point, and recently advised institutional medical officers to approach their members of Parliament on the matter. The London County Council, which has secured a saving of £1,500 a year by the new rule, allows the payment of travelling expenses up to 2s. 6d. At a recent inquest this provision secured for the medical superintendent of Shoreditch Infirmary the offer of 2d. for his tram fare to the Southwark coroner's court.

#### A CODIFICATION OF RULES FOR SPECIAL SCHOOLS.

In the past half-dozen years there have been issued by the Board of Education many memorandums giving regulations regarding the conduct of special schools provided for under various statutes. The Board has now issued in a single set of regulations<sup>1</sup> the requirements which have hitherto been contained in these several regulations. The codified regulations deal with medical inspection and treatment of school children in elementary schools and in secondary schools; with the provision of meals; with schools for the blind, deaf, defective, and epileptic, and the higher education of such; also with nursery schools, with physical training, and with grants to institutions not provided by the local education authority. In a covering circular letter

it is stated that the new regulations are in the main the codification of existing provisions, but there are changes in the omission of requirements specifically laid down by statute, and by the limitation of the regulations to such as experience has shown to be essential. Besides these changes there are some in substance to which attention is drawn in the circular letter. The chief of these appears to be related to the training of such children as are blind and deaf. Hitherto it has been a common custom to retain children over age—that is, over the age of 16 years—where it was considered that a further period of school might be of advantage. The custom was illegal, and gave rise in some instances to difficulties. Now that the further training of these children is provided for elsewhere the Board has decided that it will not for its part consent in future to the retention of any child at a special school after the date on which he ceases to be under an obligation to attend school. The change will be advantageous for these older children did not mingle well with the very young children who form the greater number of the special classes. There is one cause for complaint in the manner of the drafting of this circular letter: it is a case of continued discussion by reference. Such a sentence as "This Article takes the place of the former Article 9 (b) of Grant Regulations No. 6, and Articles 3 (b) and 21 of Grant Regulations No. 19" may be necessary, but is apt to produce irritation in the mind of the reader; whereas the use of the more popular "parallel column," showing the old and the new, would impress and inform.

#### THE BACILLUS OF NECROSIS.

THE "bacillus of necrosis" is commonly found as a saprophyte in the digestive tract of many herbivorous animals. In some circumstances it may penetrate the tissues, and, adopting a parasitic existence, cause very considerable disorders. A varying clinical picture is seen, but a characteristic necrosis is always present. The organism has been recovered from many mammals and birds, and is much more familiar to the veterinary surgeon than to the medical practitioner. The recent clear summary of our present knowledge of this organism by Césari<sup>1</sup> is therefore the more useful. The systematic position of this bacillus is by no means definite. Its generally accepted name is *Bacillus necrophorus*, but the American Association of Bacteriologists considers that it belongs to the genus *Actinomyces*, a genus of fungi to which also belongs the organism of actinomycosis. It was first discovered by Locflier in 1884, and since that date has been extensively studied by many workers. It is very pleomorphic; in young lesions it most commonly appears as long filaments, varying in length from 10 to 100  $\mu$ ; in older ones it is as a rule bacilliform (about 2 to 3  $\mu$  long); while it sometimes appears as a coccus with a diameter of 1.5  $\mu$ . The organism is Gram-negative, and is easily stained by most basic aniline dyes, when it shows chromatic granules—a fact which causes some bacteriologists to place it in the genus *Corynebacterium*. It is immobile, non-sporulating, and non-flagellate. It is strictly anaerobic, but can grow under aerobic conditions in the presence of *B. subtilis*, calcium sulphate, and other reducing agents. It is not difficult to cultivate, growing at 37° to 38° C. in a variety of media and forming characteristic growths. In liquid media—especially glucose broth—it produces a thermolabile toxin. The bacillus may be recognized by its morphology, staining reactions, and its cultural characteristics. The diagnosis may be confirmed by animal inoculation, the rabbit being the animal of choice. Many specific infections (ophthalmic) are due to this bacillus, although, as a primary agent, its necrotic action may open the way to secondary infections. It can, moreover, cause medical and surgical conditions. It can, moreover, cause medical and surgical conditions.

<sup>1</sup> Draft Statutory Rules and Orders, Education, England and Wales. The Board of Education (Special Services) Regulations, 1925. (Pp. 18. Price 5d. net. With covering circular letter No. 3725.)

<sup>1</sup> Rev. Path. Comp., November, 1924, pp. 1-10. Medical Council and R.F.P.S.G. Glasgow.

existing lesion or disease as a secondary invader. In the horse it is regarded as the essential agent of a specific necrosis of the extremities and of an ulcerative dermatitis of the hip; it has also been found in the diphtheritic exudate covering ulcerations in the large intestine. In young cattle it causes a very serious "calf diphtheria," a disease characterized by the appearance of plaques and ulcers at the back of the mouth. It also gives rise to a caseous necrosis of the digestive tube in calves and an epizootic necrobacillosis in fully grown animals, with necrotic or purulent foci in the lungs and liver, and ulcers in various parts of the intestinal tract. In these animals also it is the agent of various epizootic outbreaks, the bacillus being found on the genitalia of cows, in lesions on the feet (epizootic contagious "foot rot"), and in a nodular necrotic hepatitis frequently seen in slaughtered animals. In sheep this organism is the cause of epizootic "lip-and-leg disease," characterized by ulcerative plaques on these situations and on the external genitalia, and showing some resemblance to foot-and-mouth disease. It also produces hepatic lesions in this animal as in cattle. In the pig it is present in diphtheritic ulcers in the intestinal tract, while in dogs it sets up a fistulous dermatitis in the interdigital spaces and in other positions exposed to friction. It is the agent of other epizootic infections in animals, domestic and wild, and is frequently found in the lesions of avian diphtheria in fowls. The pathological picture in the different diseases is very varied; but the underlying process is constant in all. The course of the disease depends partly on whether the bacillus remains localized or becomes generalized, and partly on the sensitiveness of the host to the toxin. When the animal is very sensitive the process is characteristically necrotic; when it is resistant the leucocytes alone die, and the lesion is suppurative. Accordingly, as in tuberculosis, necrobacillosis appears as a disease which, single in principle, is multiple in expression. It would seem legitimate to expect that an organism which affects practically all the higher mammals would not spare man. Such infections are, however, extremely rare, and in most cases such a diagnosis amounts to no more than conjecture. Ellermann has cited one case where this bacillus caused a pseudo-diphtheritic affection resulting in the death of a child. Several more recent instances have been recorded, but although it is highly probable that this organism was the cause of some of the lesions it has not been proved to be so. Man may be resistant to the disease, but that he is not entirely so was proved thirty years ago, when Schmorl accidentally wounded his hand with a culture tube of the bacillus. However, the risk of human infection is infinitely less than in the case of other animals, and, admitting that the organism can have a pathogenic action in man, it would only endanger those who have sick animals under their care. Nevertheless, a study of the flora of necrotic or gangrenous lesions of the extremities and the mouth might possibly bring to light the presence of this ubiquitous bacillus in man.

#### THE REPROACH OF BRITAIN.

The visit of foreign health officers to this country to study public health administration, arranged, for the third year in succession, by the League of Nations, began on February 28th, and came to an end on March 23rd. The countries represented were Canada, Denmark, Estonia, France, Greece, Holland, Italy, Jugoslavia, Norway, Prussia, Russia, and the United States of America. After a busy day in London the party divided and visited Leeds, Easington, and East Riding (where they were guided by Dr. J. J. Service and Dr. J. R. Kaye), Middlesex and Willesden (guided by Dr. G. F. Buchan), and Staffordshire (guided by Dr. W. D. Carruthers and Dr. J. J. Service). The visit of foreign health officers to this country to study public health administration, arranged, for the third year in succession, by the League of Nations, began on February 28th, and came to an end on March 23rd. The countries represented were Canada, Denmark, Estonia, France, Greece, Holland, Italy, Jugoslavia, Norway, Prussia, Russia, and the United States of America. After a busy day in London the party divided and visited Leeds, Easington, and East Riding (where they were guided by Dr. J. J. Service and Dr. J. R. Kaye), Middlesex and Willesden (guided by Dr. G. F. Buchan), and Staffordshire (guided by Dr. W. D. Carruthers and Dr. J. J. Service).

R. H. H. Jolly). The three parties reassembled in London on March 9th for the study of health schemes and institutions in the metropolitan area, and on March 23rd were entertained at luncheon by the Government. Sir John Gilmour, Bt., D.S.O., M.P., Secretary for Scotland, who was in the chair, after giving the toast of the King and of the sovereigns of the kingdoms and the presidents of the republics represented, gave that of the guests. He welcomed them in the name of the Government, and expressed the hope that their visit would, through the personal intercourse which had taken place and through the friendly reception they had met with, contribute to the cause of peace, and by the interchange of opinions promote the development of public health science and administration. He coupled with the toast the name of Dr. M. D. Horst, medical officer to the city of Leyden, Holland. Dr. Horst, in his response, said that this visit, which had been rendered possible by the financial support of Mr. J. D. Rockefeller, would be productive of much good, and would, as the chairman had said, contribute to the cause of peace. Foreign countries ought to act together, like the organs of the body, for the good of the whole. The visitors were much indebted for the great pains taken in the arrangements for the tour to the Society of Medical Officers of Health and its indefatigable secretary, Mr. G. S. Elliston, and also to many individuals whose hospitality had rendered the visit most agreeable. He praised the public health administration of this country and the judicious way in which it was co-ordinated through the Ministry of Health. He commended in particular the progress that had been made in school hygiene and in the care of defective children; there was, however, one respect in which Great Britain was lamentably behindhand, and that was in vaccination. It appeared that a large proportion of the children attending school were unvaccinated. So serious was this that other countries had been compelled to take notice of it, and in his own country, where a bill had been introduced to enforce revaccination, one of the chief arguments used in its support was the unvaccinated condition of certain neighbouring States. It was a strange thing to find the country of Jenner in this category, but other countries had to face the fact. Turning then to general principles, he said that it was very necessary for the State to take a part, not only in public health administration, but also in the scientific study of hygiene. But too much State interference was to be deprecated. The spirit of science was the spirit of liberty, and there was a risk that State interference, if not judicious and well timed, might have the effect of retarding progress. He concluded by proposing the toast of His Majesty's Government, which was acknowledged by Sir John Gilmour in his own name and in that of Viscount Peel, First Commissioner of Works, who was also present.

#### THE SUFFIX "-ITIS."

It is very generally assumed by medical men and by many of the general public that the suffix "itis" implies inflammation, that etymologically "appendicitis" means inflammation of the appendix and "arthritis" inflammation of a joint. As long ago as 1836 a radical newspaper, desirous of ridiculing the special constables whom the Government of the day had enrolled to cope with the Trafalgar Square rioters, headed an article "Truncheonitis," any stick being good enough with which to beat the Home Office dog. In this instance the subject of the article was not "inflammation of a truncheon," but what might be called "the truncheon disease." Recently, in an address to the History of Medicine Section of the Royal Society of Medicine, Dr. J. D. Rolleston said that "Bretonneau invented the new word 'diphtherite,' derived from the Greek *δέρμα*, meaning a skin or leather coating." Boisseau attacked this term "on the ground that it must

mean 'inflammation of a skin.' Bretonneau, however, who was a better Hellenist than his critic, pointed out in the supplement to the treatise on diphtheria that the termination 'itis' did not really indicate inflammation, but was merely a feminine adjective often used as a substantive, the word *πόρος* [disease] being understood, so that 'diphtheritis' merely meant the pellicular disease." Since Bretonneau's time other writers have pointed out the mistake of Boissieu, who, however, was not alone in making it. In the *New English Dictionary* (in the volume H to K, published in 1901), under the heading "Itis," the true meaning of this suffix is stated. The Greeks used the word *ἀρθρίτις* (arthritis) to signify, not inflammation of a joint, but disease affecting a joint, and similarly *νεφρίτις* (nephritis), *πλευρίτις* (pleurisy), *ραχίτις* (rachitis) for disease of the kidneys, the chest wall, and the spine respectively, without any relation to inflammation. The history of the recurrent discussions of the meaning of 'itis' is a good example of wasted effort, for the whole question had been settled as early as 1826 in the excellent *Kritisch-etymologisches medicinisches Lexikon* of L. A. Kraus, published in Göttingen and Vienna in that year. Under the heading of "Arthrodynia=Arthritis" the true meaning is given, and comment is made on the "new" custom of using the suffix to indicate inflammation. Again, under "Iritis" the custom of misapplying the termination "itis" is further condemned as a neologism, and particularly its use with roots of Latin origin, such as conjunctivitis and many others. "Diphtheritis" does not appear in the *Lexikon* of 1826, but in the appendix published six years later it is to be found with the primary meaning, "inflammation of a membrane," and the secondary, "according to Bretonneau and others=laryngitis, tracheitis, etc." It is to be feared that, however much we may regret the inaccuracy of the present usage, based as it is upon mere ignorance, it is too late to correct it, and we must submit to seeing medical literature disfigured by such monstrosities as "diverticulitis." It is an axiom of economists that bad money in circulation will always drive out and replace good money, and it has sometimes seemed to us, in our more pessimistic moments, as if a similar law regulated the use of words, as shown in the disappearance of "trustworthy" and its replacement by "reliable," despite the gallant and protracted defence made by the *Times* and some other papers.

#### THE F.M. AND P.G.A.

THE discussion on post-graduate teaching in London, promoted by the Fellowship of Medicine and Post-Graduate Association, was quite well attended, and, as will be seen from the report at page 613, was adjourned until April 8th. The date is perhaps not very well chosen, as it will be the Wednesday before Good Friday. Still, it may be hoped that if another day cannot be found there will be a good attendance on that occasion. The arrangements for the meeting last week left something to be desired. The honorary secretaries had issued a circular letter stating that the object of the meeting was to ascertain how the convenience and requirements of those who wished to pursue post-graduate study in London might best be met; it was added that, after a brief account of the aims and objects of the Fellowship and of its present arrangements for co-operating with hospitals, there would be a discussion, when criticisms of the existing arrangements and suggestions for improvement would be welcomed. The letter asked persons addressed, if unable to be present, to send a written expression of their views. To those attending the meeting last week a typewritten document was given on entering the Barnes Hall of the Royal Society of Medicine. This document contained a list of fourteen opinions and suggestions received; it was headed "Fellow-

ship of Medicine and Post-Graduate Association," and, judging from some of the speeches, many of those who attended must have thought that the document contained a plan favoured by the executive of the Fellowship. After brief opening statements by the chairman and one of the honorary secretaries, statements were made by a representative of the Director-General R.N., and by Sir William Leishman, Director-General of the Army Medical Service, setting out the plans for post-graduate study in force for medical officers of those two services. These statements induced Mr. Zachary Cope to express the opinion that some national scheme ought to be set up whereby civil practitioners who felt the need of a "refresher" course could have adequate opportunity for taking it. This, of course, was very good counsel, but it is what all those interested in post-graduate study in London have been striving to achieve for the last six years without the degree of success which so much energy and good will ought to have attained. One speaker, indeed, declared that he did not know whether there were two bodies—the Fellowship of Medicine and the Post-Graduate Association—or a single body formed by a combination of the two. No doubt he ought to have known, but that he did not seems to argue some defect in propaganda, or at least in the preparations for the meeting; those attending would have profited more from a brief printed statement of the methods of the combined association, its successes and failures, than from the paper of disjointed suggestions with which they were presented. We hope that this defect will be remedied at the adjourned meeting. As has been said, one of the objects of the promoters of the meeting was to learn what sort of post-graduate facilities general practitioners desire, and upon this head a certain amount, but only a small amount, of information was tendered. There is, however, the other side of the matter, and that is, what can be offered without disturbing the arrangements for undergraduate instruction, which is the main purpose of the medical schools. Upon this point we may, when the discussion is resumed, hope for enlightenment from Sir Thomas Horder and Sir Holburt Waring, who respectively proposed and seconded the motion for adjournment.

#### THE TAUNGS SKULL.

At a meeting of the Royal Physical Society of Edinburgh on March 16th, when Dr. James Ritchie was in the chair, Professor Arthur Robinson lectured upon the Taungs skull, described by Professor Dart of the University of Witwatersrand in *Nature* and discussed by Sir Arthur Keith in our issue of February 14th (p. 325). Professor Robinson compared the photographs and tracings published by Professor Dart with photographs and tracings of some of the chimpanzee skulls in the Edinburgh University Anatomy Museum, and especially those of four skulls of chimpanzees of the same age as the Taungs skull. Professor Robinson considered that the Taungs skull differed less from one or other of the four specimens of chimpanzee skulls than the extremes of the four differed from one another. In his opinion the Taungs specimen was the distorted skull of a chimpanzee just over four years old, probably a female.

#### THE MENTAL AFTER-CARE ASSOCIATION.

THE Mental After-care Association was established forty-five years ago through the exertions of the late Rev. Henry Hawkins (then chaplain at Colney Hatch Asylum) with the support of Sir James Clark, M.D., Drs. Bucknill, Lockhart Robertson, Haek Tuke, and later of Lord Shaftesbury. The annual meeting was held, by the hospitality of the Clothworkers' Company, at their hall in Mining Lane, E.C., on March 18th. The chair was taken by the president of the association, Sir Charles Wakefield, Bt.,

C.B.E., who opened the proceedings by giving a brief account of the recent activities of the association. They had, he observed, been much increased in recent years, and had entailed considerable increase of expenditure, with which, unfortunately, subscriptions had not kept pace, so that it had been necessary to encroach on the financial reserves. The value of its homely, kindly work was increasingly recognized, and it was more and more resorted to by Poor Law and other local authorities throughout the country; it was greatly to be desired that funds might be forthcoming in connexion with possible changes in lunacy administration. The valuable services of this association and the kindly personal attention of its officers are greatly appreciated by convalescents, and it is much to be regretted that there has been of late a tendency to decline in private contributions towards assisting a return to such industrial conditions as they are capable of on the threshold of workaday life, when emerging from a period of mental confusion. The adoption of the report was proposed by Dr. Henry Rayner, for many years the chairman of the council. He stated that during the year (the forty-sixth of the association's existence) there had been an increase of 13 per cent. in the number of cases assisted. In this increase are included a considerable number of mental patients treated to recovery in Poor Law infirmaries, mental clinics, and out-patient departments of general hospitals. This was seconded by Sir Frederick Willis, K.C.B., Chairman of the Board of Control, who spoke sympathetically of the good work of the association, and expressed the hope that it might receive some recognition in any forthcoming lunacy legislation. The motion having been carried, the treasurer (Sir Maurice Craig) presented a report on the financial position of the association, which, he said, was unsatisfactory owing to the excess of expenditure over income in the past year and for the two preceding years. This was a source of great anxiety to the council. In 1923 the expenditure exceeded the income by £203 6s. 8d., and the council was obliged to sell stock to meet this; and in 1924 the excess amounted to £1,163 3s. 3d. The bulk of the expenditure was for the cottage homes to which the patients are sent to consolidate convalescence, and as this expenditure had to be met week by week it was impossible to contract any indebtedness in connexion with it. The motion for the adoption of the report was seconded by Mr. Lionel Faudel Phillips (honorary treasurer of Bethlem and Bridewell Royal Hospitals). The re-election of officers was proposed by Dr. Wolsley-Lewis (medical superintendent of Maidstone Mental Hospital), seconded by Dr. Percy R. Smith, and carried. A generous donation of £500 from the president (Sir C. Wakefield) towards the necessities of the association, and a contribution from the Clothworkers' Company of £10 10s., were announced. During the past year H.R.H. the Prince of Wales has graciously consented to become the patron of the association, following the example of His Majesty the King, who had subscribed £100 last year to its funds.

#### THE ANNUAL MEETING, BATH, 1925.

THE committee responsible for the organization of the Pathological Museum is anxious to secure the co-operation of the officers of the various scientific Sections at the forthcoming Annual Meeting in Bath of the British Medical Association next July. The committee will be glad to take charge of, and place in the museum for exhibition, any specimens, casts, photographs, diagrams, or microscopic slides during the time they are not required by those who are reading papers or taking part in the discussions. Every care will be taken of specimens, and the contents of the museum will be insured. We are asked to announce also that active preparations are being made for ladies' sports in connexion with the Annual Meeting at Bath. The local golf and tennis clubs are making the visitors

honorary members, and it will greatly assist in the arranging of matches and competitions if intending players would send their names in advance to Mrs. Doveton, 16, Queen Square, Bath, who is the chairman of the Ladies' Sports Subcommittee.

#### THE TEACHING OF INFANT CARE TO SCHOOLGIRLS.

SINCE the memorandum (Circular 758) prepared by the Medical Department of the Board of Education was issued in 1910, the interest in maternity and child welfare has enormously increased, and its importance has been more generally recognized. In a new memorandum (Circular 1353) on "The teaching of infant care and management to schoolgirls" we find the following passage, which may be taken to epitomize the Board's point of view: "If it be granted that the mother does not possess an instinctive knowledge of infant management, and may make disastrous blunders if she tries to bring up her baby by the light of nature, it is evident that at some period of her life she must learn the art and practice of mothercraft. What is the best time for such teaching? Should she wait until the baby is born and the health visitor comes to advise her? Should an endeavour be made to interest all newly married women in the welfare of the children who may come to them? Should instruction be given to young women before marriage? Or, should we begin with the schoolgirl? Something may be done at any and all of these stages, but it seems desirable that the elements of this knowledge should be acquired while the girl is still at school. This is the only time when we can make sure that she shall have some teaching in mothercraft." The Board expresses an earnest hope that mistresses responsible for girls who are approaching the end of their school life will consider what teaching such girls may properly receive in the care of their own health and in the management of infants and little children. The teaching of infant care in public elementary schools is discussed under the following headings: the nature of the course, the teacher, when the course should be given, and where infant care should be taught, including co-operation with infant welfare centres. Since different localities and personalities must always produce their own particular problems, the Board has refrained from making fixed regulations upon this subject. Rather has it emphasized the elasticity of its suggestions, leaving much to the initiative of individual mistresses. Medical officers engaged in maternity and child welfare work will, we believe, welcome an opportunity to co-operate with the schools and to give all possible assistance in facilitating the teaching of so important a subject. The memorandum closes with a brief recommendation for the teaching of infant care in secondary schools and in day continuation schools. In the interest of the health of the community it is to be hoped that the teaching of infant care will shortly be included in the curriculum of all schools for girls.

THE March number of the *Canadian Medical Association Journal* contains a full report of the Conference on the Medical Services in Canada arranged by the Canadian Medical Association, and held in Ottawa from December 18th to 20th, under the chairmanship of Dr. Alexander Primrose, C.B. Among the subjects discussed were medical education and the conditions of issuing and controlling licences to practise medicine, post-graduate medical education, the need of a full-time local health organization throughout the country, health insurance, and maternal mortality. All the provinces were represented, and also the medical colleges. It was unanimously decided that the conference should be held every year.

1 Circular 1353. Issued by the Board of Education, London: H.M. Stationery Office, 1925. (Medium 8vo, pp. 14. 2s. net.)

## THE HEALTH OF THE ROYAL AIR FORCE IN 1923.

THE Report on the Health of the Royal Air Force for the year 1923,<sup>1</sup> just published, is an admirably compiled document. The vital statistics are so tabulated as to show the incidence of sickness in great variety of detail, contrasting favourably in this respect with the recently published Army Report for 1922.

The ratio of admissions to hospital for the whole force was 473.8 per 1,000 in an average strength of 29,771, as compared with 514 in 1922 and 497.3 in 1921. If, however, trivial cases of sickness of less than forty-eight hours' duration are added the ratio exceeds that of the previous years, but the increase is due entirely to trivial cases in the United Kingdom. Injuries were the chief cause of admission, followed by diseases of the upper air passages, sandfly fever, and malarin. Venereal diseases, which caused the highest ratio of admissions in the army in 1922, accounted for comparatively few cases, the ratio being 23.8 per 1,000 in the United Kingdom, 44.3 in the Mediterranean littoral, 21.9 in Iraq, and 21.1 in India. These figures are in marked contrast with 254.2 per 1,000 in the Army of the Rhine and over 100 per 1,000 amongst troops in Gibraltar, Egypt, and Malta in 1922; and in marked contrast also with Air Force sickness during the later years of the war and after the armistice.

The high incidence of injuries was chiefly due to athletics, which accounted for 35.6 per cent. of the total injuries. Flying accidents accounted for 6.3 per cent. only of the injuries, practically the same as in 1921 and 1922. The deaths from flying accidents were, however, considerable—46 in 112 accidents, as compared with 50 in 102 accidents in 1922. Of the 46 deaths, 33 were amongst officers and 13 amongst airmen; 38 injuries and 1 death occurred from swinging the air screw, as compared with 23 injuries in 1922 and 35 in 1921; several accidents with 5 deaths occurred in connexion with motor vehicles. In a table (VIII) showing the incidence of disease and injury amongst the different trade groups of the R.A.F., the driver group showed a high injury ratio and the highest ratio of sickness. The venereal ratio in this group was markedly high, 34.4 per 1,000, as compared with only 1.3 amongst officers, cadets, and air pilots. It may be noted, however, that the venereal ratios in this table seem to exclude syphilis, as they do not correspond with the ratios for venereal diseases in the two following tables.

A large proportion of the total sickness in stations abroad was due to malaria in Basrah and sandfly fever in Hinnadi and Mosul. In Hinnadi sandfly fever caused the high admission rate of 640 per 1,000, and for all stations in Iraq a rate of 301.6 per 1,000.

A feature of the statistical tables of diseases generally and of tropical diseases in particular is the disintegration of disease groups into individual diseases, as used to be the case in the old army reports. The value of this can hardly be overestimated, and it is gratifying to find such group diseases as malaria and dysentery disintegrated into their different causative agents and into primary and recurrent attacks. An interesting conclusion that can be drawn is that the bacillary type of dysentery appears to be confined almost entirely to the Mediterranean littoral and the amoebic type to Iraq and India. Only 20 cases of typhoid fever with 3 deaths are recorded, all but 6 in Iraq. Fourteen of the cases are stated to have been fully protected by prophylactic inoculations. A severe epidemic of cholera broke out in Abadan in Persia and spread rapidly throughout Iraq during the year, and an epidemic of plague occurred in Basra; 4,078 inoculations against cholera and 1,000 against plague were carried out amongst R.A.F. personnel, and no cases occurred.

Some statistics of measurements and other physical data

in connexion with candidates for cadetships, tests of serving officers, and medical examination of recruits, are tabulated in the report. A new classification of officers in respect of their medical fitness was adopted in 1923, the letter A representing fitness for aerial duties and the letter B fitness for ground duties, with numeral subdivisions under A to represent fitness for full or limited flying duties and for combatant and non-combatant passenger duties, and lettered subdivisions under both A and B to represent fitness for home service only, temporary unfitness, or permanent unfitness. Thus an officer labelled A.h Bh would indicate limited fitness for flying at home only and fitness for ground duties at home only. The tests applied in 1923 and 1922 at home and abroad are stated to have given great uniformity in results, indicating consistency in technique. With regard to recruits, the causes of rejection were chiefly dental defects, poor physique, diseases of the heart, deformities of the feet, defects of vision, and middle-ear disease; 4,288 out of 12,092 recruits were examined by civil medical practitioners, and 1,752 rejected. Excluding these 1,752, the balance of 10,340 were examined by R.A.F. medical officers and 4,935 rejected.

The report concludes with an account of the aerial transport of some 200 cases of diarrhoea and dysentery from a column of British troops operating in Northern Kurdistan to Baghdad in Vickers-Vernon aeroplanes. The evacuation was carried out over a flying mileage of 9,615 miles in 128½ hours flying time. One aeroplane with sick crashed in inaccessible country, but was brought to the ground so skillfully that none of the sick were injured, and one patient actually had to be roused from sleep after the aeroplane had come to rest.

Other features of interest in the report are the summaries of the sanitary conditions of R.A.F. stations and the research work in connexion with phlebotomus fever and the bionomics of the sandfly. Attempts were made to transmit by sandflies the infective agent of Oriental sore, but the results were negative.

If the reports on the health of the Royal Air Force continue on the same lines as that under review they should provide in time a valuable series of comparative statistics. One point, however, must be noted. The ratios are based on small average strengths in the different geographical areas, and are consequently liable to great fluctuations from minor causes, much more so than ratios based on large numbers. In forming comparisons this fact will have to be borne in mind.

## ROYAL MEDICAL BENEVOLENT FUND.

At the last meeting of the Committee forty-two cases were considered and £642 11s. voted to forty applicants. The following is a summary of the new cases relieved.

Widow, aged 51, of M.D.Glas. who died in May, 1924. She is left with three sons; the eldest is a dental apprentice, the second a junior clerk at 15s. a week, and the youngest is at school. Applicant's only income is a share of a trust, £32, and the estimated profit from one boarder (5s. a week); other charities have granted her £38. Rent and rates come to £126 per annum, and the house is rented to May, 1925. Applicant is endeavouring to find a smaller one. Voted £20.

Daughter, aged 59, of M.D.Edin. who died in 1857. For the last thirty years she has maintained herself by painting Christmas cards, but is now hemiplegic. Only income an annuity of £50; rent £27 per annum. Voted £20.

Daughter, aged 23, of M.B.Edin. Applicant has been trained as a milliner, and her aunt is now endeavouring to get her to a cousin in Montreal, who has a millinery business; the money has been raised with the exception of £20. Voted £20.

Subscriptions may be sent to the Honorary Treasurer, Sir Charters Symonds, K.B.E., M.S., at 11, Chandos Street, Cavendish Square, London, W.1.

The Royal Medical Benevolent Fund Guild still receives many applications for clothing, especially for coats and skirts for ladies and girls holding secretarial posts, and suits for working boys. The Guild appeals for second-hand clothes and household articles. The gifts should be sent to the Secretary of the Guild, 58, Great Marlborough Street, W.1.

<sup>1</sup> Report on the Health of the Royal Air Force for the Year 1923. London: H.M. Stationery Office. February, 1925. Air Publication 1103. Pp. 71; 4 charts, 25 tables. 3s. 6d.)

## Scotland.

### ACHIEVEMENTS OF PREVENTIVE MEDICINE.

AN address was delivered by Dr. Walter Elliot, M.P., Under Secretary of Health for Scotland, to the students of the Anderson College of Medicine, Glasgow, on March 12th, dealing with the achievements of preventive medicine. Mr. J. B. Kidston, chairman of the governors of the college, presided, and the occasion was the closing of the winter session and presentation of class medals. Dr. Elliot at the outset remarked that in the last century the problems of preventive medicine had to do with the conquest of infections. Between 1801 and 1851 the population had increased from 77,000 to 345,000 (346 per cent.), and another 650,000 people came into the town during the second half of that century. The first quarter of a million increase was accompanied by a tremendous increase in the death rate, and the last 600,000 by an equally striking decrease. The expectation of life of a 10-year-old boy in Glasgow in 1821-27 had been 42 years; in the period 1832-34 it had fallen to 37 years; in 1870-72 it had risen again to 40 years; while at the present day it was as high as 50½ years. Half of every thousand boys born in Glasgow as late as 1870 were dead at the age of 25 years, whereas at the present day half of them were alive at 58 years. Estimating that improvement in round figures, it meant that the present population of the city would live an aggregate of twenty million years more than a similar number half a century ago; and averaging £50 value for the year, that meant an increase of something like £1,000,000,000 in the life capital of the city. It could not be said that people were being kept alive who would be better dead, seeing that the improvements were more at the age of 25 years than at that of 70 years. This achievement of preventive medicine was largely due to the conquest of infections. In England and Wales between 1871 and 1880, roughly speaking, 470,000 people died from the great group of fever diseases, whereas from 1911 to 1920 the deaths not only did not increase, but were reduced to 243,000. The same thing applied to tuberculosis, the deaths for the respective decades being 697,000 and 513,000. On the other hand, measles and whooping-cough had not been conquered. In England and Wales between 1871 and 1880 there were 91,000 deaths from measles, while in the period 1911-20 the numbers rose to 98,000. Against these figures he would mention small-pox, the deaths from which fell from 57,000 in the first period to 140 in the second, and typhus fever, for which the figures were respectively 13,000 and 50. Measles was one of the chief killing diseases in Great Britain, and was responsible for over 100,000 deaths in Scotland alone. It was impossible to treat all cases of measles in hospital; he thought only 25 per cent. should have hospital treatment, and that the remainder should be dealt with individually; he favoured better nursing and visiting, and a more rigid and earlier notification of cases. Speaking of London, he said that London was not recruited from the country, the increase of population coming from within the city, and yet the death rate in London was far below the death rate in the very heart of many of the Scottish counties. Emphasizing the necessity for purifying the air in cities, he said that the death rate in London on November 17th, 1923, was at the rate of 10.9 per 1,000, on November 24th it was 11.9, and on December 1st it rose to 15.4, solely owing to an intense and heavy fog prevailing during November 24th and 25th. So far preventive medicine had been helpless before great epidemics such as influenza, and they had as yet no clues for many of the individual diseases which had to be attacked.

### PRESENTATION TO SIR HAROLD STILES.

Sir Harold Stiles, who recently retired from the chair of clinical surgery in the University of Edinburgh, has been presented by the students with a beaten silver rosette. Mr. J. B. Colquhoun, president of the Students' Representative Council, who presided at the gathering, referred to the work Sir Harold Stiles had done for students in the

University Court and to his founding of the Alumni Association. Mr. A. W. Sanderson, in making the presentation, said it was the privilege of the students to have organized the gift. It was, he said, by courage, sacrifice, and perseverance that Sir Harold Stiles had added fresh lustre and dignity to the chair of clinical surgery, and his name would be added to the illustrious list of former occupants—Lister, Annandale, and Caird. Sir Harold Stiles expressed his gratitude for the hearty reception he had received that day. He said that when he became a medical student at Edinburgh forty-five years ago he vowed never to leave the city unless obliged; he had fulfilled that vow. In acknowledging the gift on behalf of Lady Stiles and himself, Sir Harold said that it would be preserved as a priceless heirloom and token of their goodwill and mutual affection.

### MATERNITY TREATMENT BY MEDICAL WOMEN IN EDINBURGH.

The annual meeting of the Edinburgh Hospital and Dispensary for Women and Children was held on March 20th at Bruntsfield Hospital, Edinburgh, when Mrs. J. C. Johnston was in the chair. The annual report, presented by Lady Walker, referred particularly to the new Elsie Inglis Memorial Hospice at Spring Gardens, Edinburgh. Work on the new maternity hospice had been considerably retarded by a strike, but the building would be ready to receive patients in the coming summer. The problem of providing a hospice for ante-natal and post-natal clinics had been partly solved by the purchase of a steel double house, but further extension of the out-patient premises would soon be necessary, because attendance at the ante-natal clinics had more than doubled during the past two years. Funds were urgently needed to provide one or two extra wards at the Bruntsfield Hospital in order to relieve the pressure on the gynaecological beds. The financial report, presented by Miss Eveline Maclaren, LL.B., stated that the ordinary expenditure at Bruntsfield Hospital, the dispensary, and the hospice had amounted to £7,903 and the income to £7,570, leaving a deficit of £333, which, however, was less than that of the previous year. A total sum of £27,445 had been paid up to date for the new hospice. Dr. A. B. Lothian, one of the attending medical officers, said that while medical women no longer needed to demand encouragement of their work, that more happy state of matters was not entirely an advantage. The woman doctor was quite a professional rival to the male doctor, and, partly owing to that and to the increasing number who qualified, it was difficult for women to get hospital training. She therefore urged the need of a fully equipped hospital for the training of women, and this meant more ward accommodation in the hospital. Women doctors were now beginning to find themselves able to organize team work, and this development was increasing the claim of their dispensary on the good will of its supporters. The chairman said that the new buildings, when completed, would give women doctors an unrivalled opportunity to pursue that line of maternity work in a definite intensive hospital service in a part of Edinburgh which had never had a proper hospital service, or had always been so far away from any out-patient department that hospital work had not affected the lives of the people.

### NOTIFICATION OF CHICKEN-POX IN EDINBURGH.

In view of the prevalence of small-pox in several districts in England, the Infectious Diseases (Notification) Act, 1893, is to apply within the city of Edinburgh, so as to include chicken-pox, from March 23rd till June 30th, 1925. The co-operation of the medical officer of health in any case of doubtful diagnosis will be cordially provided. The number of cases of chicken-pox in hospital during the week ending March 14th was 7, as compared with 9 in the previous week; 110 cases of measles were notified during that week, and 123 cases of whooping-cough; the number of fatal cases of measles was 6 and of whooping-cough 7. The principal other diseases notified were scarlet fever (57) and diphtheria (42).

## MEMORIAL TO DR. EBENEZER DUNCAN.

A memorial to the late Dr. Ebenezer Duncan, one of the founders of the Victoria Infirmary, Glasgow, and first physician to the institution upon its opening in 1890, was recently unveiled by Sir Hector Cameron. The memorial, which is installed in the infirmary, takes the form of a bronze bearing the following inscription: "Erected to the memory of E. Duncan, M.D., C.M., F.R.F.P.S.G., to whose persistent advocacy for the need for an infirmary on the South-Side of Glasgow the Victoria Infirmary owes its origin, and who for thirty years was one of its physicians."

## GLASGOW HOSPITAL SUNDAY FUND.

The Glasgow Hospital Sunday Fund has now been in operation since 1894. The largest sum which had been obtained by direct appeals to the churches and similar institutions by the infirmaries of the city was £2,090. In 1894 the Hospital Sunday Fund raised £3,640, and in succeeding years the amount steadily increased until in 1920 the sum obtained was £11,877. As the result of trade depression since that time this level has not been quite maintained, but for last year the amount available was £10,396, and of this £10,100 was distributed to the three infirmaries in the following proportions: Royal Infirmary, with 726 beds, £4,676; Western Infirmary, with 548 beds, £3,529; Victoria Infirmary, with 294 beds, £1,893.

## BOVINE TUBERCULOSIS.

We have received a report on the detection of bovine tuberculosis from Mr. Howard Jones, of the veterinary department of the city of Edinburgh, and secretary of the Scottish Metropolitan Division of the National Veterinary Medical Association. Mr. Jones states that it has been his practice for some years to examine with the greatest care any bovine carcass in which tuberculous lesions were discovered in the liver substance or its hepatic and portal lymphatic glands. He cites the following incident and points out that it illustrates the extraordinary distribution of tuberculosis by way of the lymphatic system, which is frequently to be observed when the liver substance or the corresponding lymphatic glands are affected. As an example, the conditions found in a bullock three years old, in apparently perfect health and prime condition, having a live weight of 12 cwt. 1 qr., are described. Taking the organs in their order of removal it was found that the right and left retropharyngeal lymphatic glands were tuberculous, that two mesenteric lymphatic glands were infected, that the hepatic and portal lymphatic glands were calcifying and caseating, and that there was one small tuberculous lesion in the liver substance. The stomach, omentum, spleen, kidneys, the lung substance, and the mediastinal lymphatic glands were normal, but one right bronchial gland was tuberculous. Mr. Jones points out that to anyone acquainted with meat inspection this would not appear to be a widespread infection, and is a combination of lesions comparatively often found in home cattle. It is frequently unaccompanied by other lesions, but as this is not invariably the case a minute scrutiny is always necessary when this combination is found. On superficial examination the carcass showed a perfect state of nutrition, and to all appearance the animal was perfectly normal. There was no trace of tuberculosis in either of the serous membranes, nor were any enlarged lymphatic glands to be seen in other parts. Mr. Jones remarks that from his knowledge of the prevalent laxity in many towns, and of the need for more systematic meat inspection, particularly in rural areas, he has little doubt that in some places such a carcass would have passed into a butcher's shop without further examination. A careful investigation of the lymphatic glands revealed widespread evidence of active tuberculosis. In consequence of these findings the carcass, with all its organs and offal, was condemned. Mr. Jones considers the existence of such cases as this to be evidence of the necessity for instituting public abattoirs throughout the country, for eliminating private slaughterhouses, and for appointing properly trained and qualified inspectors to examine and pass judgement upon meat supplies.

## DUNDEE ROYAL INFIRMARY.

The work of Dundee Royal Infirmary during the year 1924 was reviewed by Mr. Drummond Taylor, chairman of the directors, at a meeting held on March 9th. The total number of patients treated in the wards during the year was 7,270, an increase of 650 over the number for 1923. The wards were constantly filled to overflowing, and in several departments there were long waiting lists, so that a considerable extension of the existing accommodation would have to be faced at an early date. The last extension (the Caird building) had been opened in 1907, and since that time the number of patients had increased from 3,651 to its present figure, the daily average under treatment having increased from 238 to 338. The income for last year amounted to £30,000 and the expenditure to almost £41,000. Last year the Dundee Convalescent Home showed a deficit of £877, and the Sidlaw Sanatorium one of £586.

## CENTRAL MIDWIVES BOARD FOR SCOTLAND.

At a special meeting of the Board for the hearing of penal cases, Dr. James Hugh Ferguson in the chair, a certified midwife was cited for failure to take and record the pulse and temperature of her patients, and for other breaches of the rules. The Board found the charges proved, and instructed the secretary to remove the name of the midwife from the Roll and to cancel her certificate. At the same session a certified midwife appeared in answer to charges of having neglected to give the necessary directions for securing the cleanliness, comfort, and proper dieting of a patient during the lying-in period, and having discontinued her attendance on the case on the third day, and other breaches of the rules; they were found proved, but to give her an opportunity of proving amendment a decision was postponed for reports from the local supervising authority.

## England and Wales.

## KING EDWARD'S HOSPITAL FUND FOR LONDON.

The annual meeting of the General Council of King Edward's Hospital Fund for London, to receive the accounts and report for 1924, was held at St. James's Palace on March 17th, H.R.H. the Prince of Wales taking the chair. The total receipts were £412,472, of which £112,240 was from the estate of the late Mr. John Wells and £50,203 from that of the late Sir Thomas Sutherland. Other legacies brought in £35,563; and the general receipts, which amounted to £214,242, included £19,751 from annual subscriptions, £2,659 from donations, £14,500 from the League of Mercy, £15,000 from the British Charities Association, £142,232 derived from investments, and £200 from the trustees of the Bawden Fund. The amount of the ordinary distribution was £235,000, as in 1923. The grants to hospitals for extensions and improvements increased by nearly £5,000, and there was a corresponding reduction in the grant for maintenance. The amount distributed among hospitals, convalescent homes, and sanatoriums during the last ten years has been £3,020,438. During the year the amount spent on administration was £10,614, as compared with £8,904 in the previous year. In addition to the cost of the ordinary administrative work, this amount included the work of the central body, which considerably increased since, under the report of Lord Carey's Committee, the King's Fund became the Local Voluntary Hospitals Committee for London. The report of the Ambulance Cases Disposal Committee, received in April, 1924, was included in our issue of April 12th (p. 684); it contained recommendations that the Distribution Committee should consider whether hospitals applying for a grant provided adequate bed accommodation for ambulance cases; also that inadequately equipped hospitals should not be retained on the list of hospitals used by the police and ambulance authorities; and, lastly, certain suggestions were made for changes in the law and the procedure in connexion with Poor Law institutions. The first two proposals were put

into force by the authorities concerned, and the third was still under the consideration of the Ministry of Health. In May the King's Fund co-operated in an inquiry, begun by the Voluntary Hospitals Commission at the request of the Minister of Health, with regard to the need for hospital extension, including the provision of accident beds. A questionnaire was issued by the King's Fund, and a report of the information obtained was presented to the Commission in November. In July the General Council decided to make use of the Wells legacies in aid of schemes of extension and improvement, and by the end of the year grants amounting to £81,000 had been approved, thus providing for an additional 301 beds, of which 53 were to be reserved for accident cases. The grants were for the most part accompanied by conditions designed to stimulate and reward efforts made by the hospitals themselves. The Wells legacies also enabled the King's Fund to enlarge the area of its operations from a radius of nine miles from Charing Cross to a radius of eleven miles from St. Paul's Cathedral. In 1919 the King's Fund issued the report of a special committee of inquiry into the question of pensions for hospital officers and nurses, and in this connexion a conference will be held shortly between the Hospital Officers' Association, the College of Nursing, the British Hospitals Association, and the King's Fund. The work of the Propaganda Committee during the year was chiefly concerned with educational programmes rather than finance. A film illustrating the work of a modern hospital was displayed at Wembley Exhibition as part of the Government programme. In October, 1924, a scheme of lectures on the work of modern hospitals was drawn up for the use of colleges and secondary schools, a panel of experts was compiled, and several lectures had already been given. The committee reported that it had secured a large number of voluntary workers, and had been assisted by the press and the co-operation of many hospital representatives.

The Prince of Wales, addressing the Council, pointed out that the accounts for the year were better than had been anticipated, and were an encouragement for the present year. The claims on the King's Fund would continue to increase, both in consequence of new hospital extension schemes and the enlargement of the area with which the Fund was concerned. The support of the public would be obtained in increasing amount when the need was realized; in this respect the value of the propaganda work of Lord Burnham's committee was very great. The Hospital Economy Committee was still engaged in the work of bringing up to date the revised uniform system of hospital accounts. His Royal Highness stated that during his absence from England his powers as president would be exercised by a committee consisting of Lord Donoughmore, Lord Cave, and the Governor of the Bank of England.

#### VENEREAL DISEASE ARRANGEMENTS IN LONDON.

The London County Council on March 17th received a report from its Public Health Committee on the working of the venereal diseases scheme during 1924. The councils of six adjoining counties and of three adjoining county boroughs participate in the London scheme, but the cases which come from the London county area are reckoned at 80 per cent. of the whole. The total number of new cases attending the clinics in 1924 was 25,573, of which 7,292 were found to be non-venereal. Of the venereal cases, those of syphilis numbered 6,626, those of gonorrhoea 11,350, and those of soft chancre 305. The total attendances at the clinics were 589,002, as compared with 555,509 the previous year. It is considered that the great increase in the ratio of attendances to new venereal cases points to the success which has followed the efforts made to secure the further attendance of patients so long as treatment is necessary. The number of bacteriological specimens examined at hospitals in 1924 at the request of and free of cost to medical practitioners was 24,797, a higher number than ever before; 405 practitioners are on the approved list for the supply free of cost of salvarsan or its substitutes for the treatment of patients resident in the county and for the prevention of the spread of the disease. It is proposed to continue the scheme for another year on the same basis as before. The total expenditure contemplated in the year

1925-26 is £122,810, compared with £124,050 for 1924-25, three-fourths of this sum being met by Government grant. The provision of £2,020 is to be made for publicity and propaganda work, and the National Council for Combating Venereal Diseases is again to be permitted to exercise such of the powers of the county council under the scheme in relation to propaganda work as are necessary for lectures, conferences, cinematograph exhibitions, and other occasions.

#### THE FREEDOM OF WEYMOUTH CONFERRED ON TWO MEDICAL PRACTITIONERS.

On March 19th the freedom of the borough of Weymouth was presented to Dr. J. Macpherson Lawrie, D.L., J.P., and Mr. H. H. Du Boulay, J.P. Dr. Lawrie, who began practice in Weymouth in 1883, has devoted himself particularly to the building of the Princess Christian Hospital, now the Weymouth and District Hospital. He was appointed a country magistrate in 1889, a member of the first Dorset County Council in 1892, and a deputy lieutenant in 1906. Mr. H. H. Du Boulay, now consulting surgeon to the Weymouth and District Hospital and to the Weymouth Eye Infirmary, has practised in Weymouth for nearly thirty years, particularly in connexion with the old Royal Hospital, now merged in the amalgamated Weymouth and District Hospital. The streets of the town were decorated for the occasion, and many speeches were made eulogizing the high services of the two new freemen of the borough of Weymouth and Melcombe Regis.

#### ROYAL DENTAL HOSPITAL, LONDON.

Much improved facilities for the treatment of children have now been obtained by the Royal Dental Hospital in London. At the annual general meeting of the governors, held on March 19th, the chairman referred gratefully to the help of Sir Oswald Stoll, who, by placing the Alhambra Theatre at the disposal of the hospital for a concert, had enabled a sum of over £600 to be raised for the children's department. The considerable enlargement has been effected partly by reorganization, and, to a certain extent, by rebuilding, and the special attention necessary in the case of children can now be more satisfactorily provided. The x-ray department has also been greatly extended, the work in it is expanding, and its value in diagnosing the more obscure diseases is becoming increasingly evident. The total number of attendances at the hospital during the past year was 54,950. A large proportion of the mortgage on the building is still outstanding, and the chairman appealed for efforts to be made to obtain a larger number of annual subscribers.

## Ireland.

#### RELIEF OF THE DESTITUTE (IRISH FREE STATE).

THE Minister for Local Government has announced that the Commission to inquire into the relief of the destitute sick and poor, including the insane poor, will consist of Mr. C. H. O'Connor, formerly of the Local Government Board (chairman), Alderman Corish, T.D., the Right Rev. Monsignor Dunne, Senator Sir John Keane, Dr. Hennessy, T.D., Sir Joseph Glynn, the Rev. M. O. Murphy (Dublin), Senator Mrs. Wyse Power, Major Myles, T.D., Mr. P. Sugrue, Commissioner for Co. Leitrim. The terms of reference are:

With the object of devising permanent legislation for the effective and economical relief of the sick and destitute poor, to inquire into the laws and administration relating thereto, and particularly as regards the following matters:

1. To inquire into the adequacy and suitability of relief which have been formulated under the Local Government (Temporary Provisions) Act, and make recommendations.
2. To advise as to whether the existing law and regulations as regards home assistance require alteration (towards securing that due provision is made for the sick and destitute poor in their own homes without avoidable wasteful expenditure on healthy persons who are incorrigibly idle).
3. To examine the law and administration affecting the relief of the following destitute classes, and to make recommendations:

committee meetings, but to ascertain through correspondence and exchange of visits the particular lines followed by surgeons at different centres in Great Britain and Ireland, and to persuade individual workers to carry out, as far as possible, some one technique through a series of at least fifty cases. Tedious clerical work would be obviated by the use of standard forms requiring simple answers (such as yes or no), and by the carrying out of statistical analyses at headquarters, the original records being returned to the sender. By this simplification of returns, and centralization of analysis, it is hoped that busy individual workers may be drawn into the fold. Those interested in the matter are asked to communicate with the honorary secretary, Inoperable Carcinoma of the Cervix Association, c/o the British Empire Cancer Campaign, 19, Berkeley Street, W.1.

#### THE SLOW MARCH OF HYGIENIC EDUCATION.

SIR GEORGE NEWMAN, in presiding at the Society of Arts on April 29th, when Dr. Andrew Balfour read a paper on "The trend of modern hygiene," confessed that he found something gravely dissatisfying in the outlook so far as education in hygiene was concerned. Someone from abroad had remarked to him, "This is the land of Jenner, and yet you have an unvaccinated people." The teaching of Jenner had gone out into all the world, and yet during the previous week 168 fresh cases of small-pox had been notified—mild small-pox, happily, but entirely unnecessary and preventable. The fundamental truth that lay behind vaccination, however cumbersome the procedure of vaccination might be, had not been grasped by large masses of the people. Only the other day, again, there was an outbreak of typhoid fever in the North of England, in which fifty cases were proved to be milk-borne from a farm where a case of typhoid fever was being nursed. Yet so long ago as the reign of Sir John Simon it was impressed upon all concerned that a case of infectious disease should not be nursed on a milk farm. Apparently each generation had to learn afresh from new disasters. In America the Schick test was widely used as an instrument for the prevention of diphtheria. But in this country, although the truth of it was known as well as it was known in New York, it was only with difficulty that it was made applicable at all. Another instance was furnished by tuberculous infection. Tuberculosis was one of 'ho most preventable and in some ways the most curable of maladies. The answer to tuberculosis was known—it was the sanatorium principle. But the sanatorium principle had still to find its application in the homes of this country. Again, there were 700,000 women who would give birth to children during the next twelve months, but not 200,000 of them would take full advantage of ante-natal care and supervision during pregnancy, with the result that child-bearing was still hazardous in England. There was one great positive result to which modern hygiene could point. A child born to-day had a prospect of life some ten or twelve years longer than had a child born two generations ago, but what he wanted to see was disease "turned off at the tap," and the only way to bring that about was to have an educated people. Dr. Balfour's paper which occasioned these remarks by Sir George Newman was a comprehensive survey of public health in its more popular aspects, from Leviticus and Deuteronomy right down to the protocols of the Health Section of the League of Nations. He spoke at length of the need for the education of the lay public. Perhaps, like other preachers of good causes, Dr. Balfour showed too great faith in the power of the press. He urged a closer co-operation between the public authorities and the newspapers, whose columns should be open to the skilled hygienist for the deliverance of his message, not in his own name, but under the aegis of a health department. It is often forgotten, however, that newspapers are neither

educational nor philanthropic institutions, but commercial concerns, and that, in those which have the widest popular appeal, a sensational, sometimes an alarmist, titbit—often inaccurate in its information, and always inaccurate in its emphasis—will have precedence over any amount of "copy" officially furnished. Dr. Balfour seemed to have discovered for himself, so far as the cinematograph was concerned, the weakness of propaganda when subject to the restraints rightly imposed by public authority. When he went to see a private exhibition of the "Swat that fly!" film, the operator, an American, said to him, "This kind of thing don't cut ice. Let me show you something with 'pep' in it," and he proceeded to demonstrate a comic film which illustrated grotesquely the advantages of life insurance—apparently the style of film to which, however good its motive, a public department could hardly give its imprimatur. That is one of the difficulties besetting the path of hygienic education. Dr. Balfour devoted much of his paper to the consideration of the private medical practitioner discharging the function, not of curing the sick, but of keeping people in health. He quoted from Dr. John Dill Robertson of Chicago, who has put this point forcibly, and even acridly, and has not hesitated to charge the general practitioner with criminal negligence for his failure in this respect. But Dr. Balfour pointed out that the same plea was urged, more quietly and effectively, long ago by Dr. John C. McVail, in the memorandum accompanying his report on Poor Law medical relief, and that Dr. McVail had more recently elaborated his theme by envisaging the physician as the health guardian, the confidant, and the philosopher at all stages of life. On the question of the possibility of periodical medical inspection of the population Sir George Newman also had a word to add. He said that the late Dr. Hermann Biggs, State Commissioner of Health for New York, dissented this point with him on his very last visit to London. Dr. Biggs was more hopeful than he—but then he came from a hopeful country!

#### HUXLEY.

THE centenary of the birth of Huxley has been celebrated this week. He was born on May 4th, 1825, at Ealing, then a village, near London. He was a brilliant boy, and entered Charing Cross Hospital Medical School with an open scholarship at the age of 16. He passed the first M.B. Lond. in his twentieth year, and within twelve months was appointed to the Medical Department of the Royal Navy. Huxley therefore began life as a member of the medical profession, though without any formal diploma; it was not until 1862 that he became M.R.C.S., and not until 1883 that he was elected F.R.C.S. He had, however, already distinguished himself as a physiologist, and after a short time at Haslar was appointed surgeon to the *Rattlesnake*, which, under the command of Captain Owen Stanley, a brother of Dean Stanley, was during the next four years engaged on a survey of the coasts of New Guinea and the Louisiade Archipelago, and of the Barrier Reef of Australia. His energy and industry while with the *Rattlesnake* expedition were extraordinary, and within a year of his return to this country he was elected F.R.S. at the very early age of 26. He entered upon his career as the champion of science, therefore, with a solid basis of technical achievement. His significance for the age was that he became the fearless defender of the freedom of science and of its right to pursue its own course untrammelled by authority. Convinced himself by the study of Darwin's *Origin of Species*, Huxley, through the sheer strength of intellect displayed in his brilliant advocacy by speech and pen, forced the public to listen, and left no man or woman of education the excuse to ignore or misunderstand the true meaning of evolution, and its importance, not only to zoology and botany, but also to palaeontology and anthropology, and even to social problems. His success

accomplishing this self-imposed task has perhaps rather obscured his extraordinary achievements as a laboratory and field worker. He took to writing as a means of livelihood—as a means, at any rate, of augmenting his meagre salary as professor of palaeontology and professor of natural history at the Royal School of Mines. It was characteristic of him that when he decided to become a writer he determined to write well. He attained his object without labour, and even to the last was in the habit of making four or five drafts of everything he published. He came to exercise a tremendous influence. "Darwin's bulldog," as he styled himself, was for years the intermediary to whom the thinking public who were not skilled naturalists owed their deepest appreciation of the problems involved. He was quite fearless. He never allowed himself to be overawed by temporal or spiritual dignitaries, and after the famous Oxford meeting of the British Association at which he administered a well merited rebuke to the then Bishop of Oxford (Wilberforce), he described himself as being "episcopophagous." He had perhaps a certain joy in combat, as was natural in so skilful and sturdy a fighter; but all through his public life of nearly forty years he was actuated always and in all matters by a simple-minded love of truth.

#### DR. JOHNSON'S DOCTORS.

ANOTHER social evening, with Sir St. Clair Thomson as host, was held at the house of the Royal Society of Medicine on May 4th. The brief address on this occasion was delivered by Dr. Robert Hutchison, who showed some Johnson portraits, the best of them by Opie, and spoke of the connexion between the great lexicographer and medicine. Samuel Johnson, said Dr. Hutchison, paid many high compliments to the medical profession. The most elegant, according to Boswell, was his remark that "every man has found in physicians great liberality and dignity of sentiment, very prompt effusion of beneficence, and willingness to exert a lucrative art without hope of lucre." Johnson might well have been impressed by the work which physicians did for nothing, because he never paid them any fees himself. "Illness is of little expense to me," he wrote, "thanks to the generosity of my physicians." After Dr. Richard Warren had been called into consultation Johnson said to him, "Sir, you come at the eleventh hour, but you shall be paid the same as the others"—and caused his servant to put a copy of the *Lives of the Poets* in Dr. Warren's coach. Warren was one of the most successful physicians of his day from a monetary point of view, with an income for many years of at least £9,000. Johnson was quite wrong in his statement that no estate had ever been made by medicine. Richard Mead was a wealthy man, Radcliffe had been a munificent benefactor of Oxford, Lettsom and Fothergill had very large incomes. In fact, Dr. Hutchison believed that, relatively speaking, the practice of medicine was more lucrative in the eighteenth century than to-day. Of the doctors of Johnson's circle, one of his most intimate friends was Thomas Lawrence, for seven years President of the Royal College of Physicians, who had a bond of sympathy with Johnson in that, like him, he suffered from convulsive movements of the head. Another was William Heberden, whom Johnson called the last of the learned physicians. Then there were Brocklesby, George Fordyce, and Lettsom. Another medical celebrity was the eccentric Sir Thomas Browne, who went about carrying a muff, a copy of Horace, and a spy-glass, and was about the only person who ventured to oppose Johnson when he was extolling Oxford at the expense of Cambridge. Nor should that curious irregular practitioner, Robert Levett, be left out of account. Johnson's own medical knowledge, Dr. Hutchison continued, must have been

considerable. He had some sound views, disapproved of periodical bleeding, fulminated against rapid diagnosis—"life is not to be sacrificed to an affection of quick discernment"—had a strong contempt for polypharmacy, and in a hard-drinking age was himself abstemious. When taken ill at Montrose he wrote out a prescription for himself in technical characters, and he did not hesitate even to prescribe for the President of the Royal College of Physicians; when Lawrence had paralysis of the hand Johnson suggested treatment by electricity. Of the physicians who attended him towards the close of his days were mentioned William Cruikshank, "a sweet-blooded man," the surgeon who was called in to scarify his legs; Percival Pott, Sir Lucas Pepys, and Sir Richard Jebb. Dr. Hutchison described Johnson himself as one who was robust but not healthy; he suffered from various complaints, including scrofula, habit-spasms, and melancholia; Johnson said of himself that his diseases were "an asthma, a dropsy, and, what is less enurable, seventy-five." All must admire his sterling common sense, his hatred of fads, his great personal courage, his compassion and charity, and the fortitude with which at last he approached death. Had his steps turned to medicine he could hardly have been a great physician. Certainly he could never have acquired the bedside manner, and his appearance in the sick-room might, as was said of Levett, have disgusted the rich and terrified the poor. Mr. Augustine Birrell, who proposed a vote of thanks to Dr. Hutchison, said that he had always admired Johnson, but after seeing portraits of twenty of his doctors he marvelled at him the more, wondering how he had survived at all. Mr. Birrell was not impressed by the portraits, save only those of Cruikshank and Brocklesby. Both these were evidently delightful fellows, though one of them (Cruikshank) took to drink, and the other was a failure in his profession!

#### HARVEY MEMORIAL: REBUILDING HEMPSTEAD CHURCH TOWER.

WILLIAM HARVEY died in his eightieth year on June 3rd, 1657, and on June 26th his remains were deposited in a vault adjoining the parish church of Hempstead in Essex. He was "lapt in lead," and on his breast in great letters was his name, "Doctor William Harvey." By the middle of the last century this vault underneath the Harvey Chapel had become ruinous. On January 23th, 1882, the tower of the church fell towards the south-west; it is still a heap of stones in the churchyard. On October 18th, 1883, the body was removed from the vault and placed with all due reverence in a handsome white marble sarcophagus erected by the Royal College of Physicians of London in the chapel above the vault. With it was deposited a leaden case containing the edition of the works of Harvey published by the College in 1766, and a vellum memorial recording the circumstances of the removal.<sup>1</sup> It is now proposed to restore the fallen church tower as a further memorial to William Harvey. The village of Hempstead lies in a sparsely populated agricultural district, seven miles from the railway station of Saffron Walden and some fifty from London. It is therefore necessary to make a far-reaching appeal for the sum of £5,000 which is needed to carry out the project. The clergy of the diocese and the Royal College of Physicians have given their hearty support, and a committee has been set up, including the bishops of the three neighbouring dioceses; the President and other distinguished Fellows of the Royal College of Physicians; Sir H. K. Anderson, M.D., Master of Gonville and Caius College, Cambridge (of which Harvey was a member); Sir Charles Sherrington, M.D., President of the Royal Society; Sir Archibald Garrod, M.D., Regius Professor of Medicine

<sup>1</sup> See BRITISH MEDICAL JOURNAL, April 11th, p. 705, where by inadvertence Levett's Christian name is given as "William."

<sup>1</sup> See BRITISH MEDICAL JOURNAL, October 20th, 1883, p. 780. Of those Fellows of the College of Physicians who took part in the ceremony there described, two, Sir Richard Douglas Powell and Sir Dyce Duckworth, are still with us.

at Oxford; Sir D'Arey Power; and Dr. A. D. Brenchley, Master of the Society of Apothecaries. The chairman is Lord Stanmore, treasurer of St. Bartholomew's Hospital, to which Harvey was physician. Donations from members of the medical profession may be sent to Dr. Sidney Phillips, joint honorary secretary of the fund, at the Royal College of Physicians, Pall Mall East, S.W.1.

#### THE CHARCOT CENTENARY.

As already announced, the centenary of the birth of Charcot will be celebrated in Paris at the end of this month. Professor Pierro Mario will deliver an éloge of Charcot at the Académie de Médecine on the afternoon of May 26th, and on the evening of the same day at a meeting at the Sorbonne, which will be attended by the President of the Republic, M. Babiniski will deliver an address, and will be followed by the official delegates of foreign Governments. Addresses will also be given by the Dean of the Paris Faculty of Medicine, by representatives of the Académie des Sciences, the Académie de Médecine, the Institut Pasteur, and a number of medical societies. On May 27th a visit will be paid to the Clinique Charcot and the Salpêtrière. On the afternoon of the following day the Municipal Council of Paris and the General Council of the Seine will hold a reception at the Hôtel de Ville. The Royal College of Physicians of London will be represented by Dr. Gordon Holmes. Dr. Farquhar Buzzard, who will attend the centenary as president and representative of the Neurological Section of the Royal Society of Medicine, will deliver a short address on Charcot at the social evening of the Royal Society of Medicine to be held on Monday, June 15th, and there will be on this occasion an exhibition in the library of books and articles by Charcot and his pupils.

#### AMERICAN RESEARCH IN VENEREAL DISEASE.

In America, in recent years, much attention has been given to the problems of syphilis and gonorrhoea, and a *Report of the Scientific Researches on the Venereal Diseases*, prepared by Dr. E. L. Keyes, has been recently published by the American Social Hygiene Association (370, Seventh Avenue, New York) by agreement with the United States Interdepartmental Social Hygiene Board. This report is essentially an epitome of the published accounts of the scientific researches concerning venereal disease that were financed and directed by the Social Hygiene Board during the years 1918 to 1921. The American Social Hygiene Association made grants subsequently to some of the investigators in order to enable them to complete their researches. The choice of subjects seems to have been particularly happy, and, though no brilliant discovery is recorded, a definite advance has been made in methods of diagnosis and treatment. The difficult problem of recognizing types of gonococci was attacked, and the conclusions reached appear to be much the same as those of British investigators—namely, that at present it is not possible to separate the strains into definite classes. Much valuable information is given as to the successful cultivation of the gonococcus, and Torrey and Buckell very rightly emphasize the necessity of a moist atmosphere for optimum growth—a point not mentioned by most writers. It would appear, however, that they allow rather too wide a margin for the reaction of the medium, and overlook the many advantages which hydrocele fluid presents over other kinds of enriching agent. Oxygen tension is not considered to be of importance. The complement fixation test for gonorrhoea has received a due meed of attention, and it is claimed to be rather more valuable in women than either cultures or films for diagnostic purposes. Much study has been devoted to the staining of *Spironema pallidum*, and a simplified tissue stain is given which appears to give good

results; it remains an open question, however, whether staining is a better method than dark ground illumination for detecting spirochaetes in surface lesions for diagnostic purposes. In this country the latter is favoured, for the reason that it is simple and rapid, and also brings out two distinguishing features of the organism—its motility and whiteness. The report, which includes a full bibliography, is an excellent summary of a valuable inquiry into admittedly difficult problems. Both clinicians and pathologists will find much information to add to their armamentaria for the diagnosis and treatment of venereal diseases.

#### MEDICINE AT THE ROYAL ACADEMY.

This year's exhibition at the Royal Academy of Arts, like its predecessors, contains a number of medical portraits and a few other exhibits of immediate interest to our readers. Of the oil paintings, No. 156 is an admirable portrait by Charles Sims, R.A., of Dr. Matthew Hay, the veteran professor of forensic medicine in the University of Aberdeen, and medical officer of health for the city from 1888 to 1923, who is shown seated in doctor's scarlet robe; it is described as a civic and academic tribute. The next gallery has a picture (225) by the same artist, entitled "The Children's Ward, St. Thomas's Hospital"; this is a balcony scene, and the boy patients, the nurses, and a house-surgeon form a delightful group, with the river, St. Stephen's clock tower, and Westminster Bridge in the background. Near at hand (192) is a portrait of a Hunterian professor, Mr. Alexander Fleming, in F.R.C.S. gown, by John Wheatley—a curious piece of work, but interesting. In strong contrast with this is the presentation portrait of Sir Humphry Rolleston, Bt., K.C.B. (260), by George Henry, R.A., a gift to St. George's Hospital by his friends and pupils. It is a dignified and pleasant likeness of the new Regius Professor at Cambridge, seated in a red chair and robed in the gold-embroidered presidential gown of the Royal College of Physicians, with the silver caduceus of John Caius in his hand. Another ceremonial painting, but more sombre in tone, is the three-quarter length portrait by Fiddes Watt of Sir Gilbert Barling, Bt., F.R.C.S. (371), robed as Vice-Chancellor of the University of Birmingham. The smallest of the medical portraits in oils, but by no means the least effective or characteristic, is a "study in scarlet" by Maurice Greiffenhagen, R.A., entitled "Sir Donald MacAlister of Tarbert, Bt., K.C.B., M.D." (477). Obvious hero is the painter's delight in a subject worthy of his brush. Other oil paintings which will appeal to medical visitors are the fine group "A Street Accident," by Glyn Philpot, R.A. (79); "The Founder's Tomb, St. Bartholomew the Great, West Smithfield," with Rahere's recumbent figure well known to all Bart's men, by Miss Irene Ryland (443); also, but from another point of view, Walter Sickert's "Freekied Boy" (460), whose features give a hint of something in a big glass jar at the museum in Lincoln's Inn Fields. Among the works of sculpture in the Lecture Room is a bronze bust of Dr. Maurice A. Cassidy (1344) by Henry Pegrain, R.A. Here also is a case of exhibits illustrative of the work of the Royal Mint during the past year (1363); it includes the prize medal of the Harveian Society of London and the Rivers Memorial Prize Medal of the Royal Anthropological Institute, both by Langford Jones; and the nurses' medal for the Bristol Royal Infirmary, an excellent little work of art by T. H. Paget. Medical visitors this year should certainly go into the Architectural Room, where, besides a number of designs for hospitals and university buildings, are the large-scale model (1201) and the plan of site (1210) for the wonderful Memorial to the Missing at St. Quentin, by Sir Edwin Lutyens, R.A., architect of the new British Medical Association House in Tavistock Square, now nearing completion.

## FOOD POISONING.

THE Medical Research Council has issued a special report by Dr. W. G. Savage and Mr. Bruce White on food poisoning,\* founded on a study of 100 recent outbreaks in this country, most of which have not been previously published. It is prefaced by a general survey of the different causes of outbreaks of food poisoning, the epidemiological and clinical features of food poisoning, the paths of infection, and prevention of food poisoning. It is an important addition to the literature on food poisoning, and the sections dealing more especially with the clinical features and prevention are discussed elsewhere in a leading article.

This report (No. 92) is a continuation of the special studies of Dr. Savage and Mr. White, published in the Medical Research Council Report No. 91, and entitled "An investigation of the salmonella group, with special reference to food poisoning" (see BRITISH MEDICAL JOURNAL, February 21st, 1925, p. 373), which dealt chiefly with the classification and distribution of the salmonella bacteria.

*Causes of Food Poisoning.*

By far the commonest cause of food poisoning in this country is infection of food by living salmonella bacteria or by the toxins of these microbes. Salmonella bacteria multiply rapidly in food without betraying their presence by any obvious decomposition, and they secrete powerful endotoxins capable of resisting temperatures as high as 100° C. In 20 of the 100 outbreaks recorded in this report living salmonella bacteria were proved to be the agents of infection, and in 14 of these 20 outbreaks *B. actyricus* was the particular member of the group found. The isolation of these bacilli is a difficult procedure, for they are fastidious in their diet, and it is worth while noting, in view of the remarks we make elsewhere about the more thorough investigation of outbreaks of food poisoning, that in 6 of these outbreaks the bacilli were only captured from material obtained at *post-mortem* examinations; if this material had not been available the bacterial cause would not have been definitely established, though deductions might, of course, have been made from other examinations.

It is well known that food in which salmonella bacteria have grown may continue to be poisonous after the bacilli themselves have been destroyed, because the toxin which these germs secrete is more resistant to heat than are the living cells. Food poisoning by the toxins of the salmonella bacteria alone is perhaps the most difficult of all to analyse, because ingestion of these toxins leaves no specific stamp upon the body tissues: thus agglutinins do not appear in the blood serum. It might be thought that the poisonous nature of the food could be demonstrated by feeding experiments on animals, but this method is not often successful because animals are exceptionally resistant to these toxins. The method of injecting extracts of suspected food parenterally has led to many false conclusions in the past and does not now command much confidence. A promising new method of study was referred to in Report 91—namely, the possibility of demonstrating toxic properties in food by feeding animals with large quantities, killing the animal nine to twelve hours afterwards, and examining the stomach and intestines for evidence of inflammatory reaction. Another new method which we believe Dr. Savage was the first to employ, at any rate on an extensive scale, is the demonstration of the production of specific agglutinins to the salmonella bacilli through the injection into animals of suitable emulsions of the incriminated food. By one method of investigation or another the authors of this report have satisfied themselves that 17 out of the 100 outbreaks should be ascribed to salmonella toxins.

Four of the outbreaks were caused by bacteria of the dysentery group. The chief interest of this observation is that it widens our view of food poisoning, for until recently it would have been denied that bacteria of the dysentery type could cause outbreaks of food poisoning indistinguishable in their clinical characters from salmonella infections.

Only one outbreak of botulism—that at Loch Maree—is represented in this series.

To summarize the cause of these 100 outbreaks of food poisoning, epidemiological and laboratory investigations, separately or together, provided evidence that 66 outbreaks were due to members of the salmonella group of bacilli, 4 to members of the dysentery group, and 1 to *B. botulinus*. The remainder were either of definitely chemical origin, or possibly due to some undetected microbe, or were not examples of true food poisoning.

*Epidemiological Features.*

Food poisoning outbreaks are commonest in the warm months of the year. The peccant food was almost invariably perfectly wholesome as judged by sight, taste, and smell. Turning to the vehicles of infection, we find that tinned food constituted 42 per cent. of the whole. Nearly all the outbreaks from undestroyed bacterial toxin arose from canned food, whereas "made up" meat was much the commonest vehicle for the living bacilli, and milk products for the remainder. The infectivity rate was high, and often all partakers of the incriminated food were made ill.

*Special Types of Food Poisoning.*

Apart from the salmonella type, there are two other forms of food poisoning which the report discusses at some length, and to which brief reference should be made here—namely, botulism and cheese poisoning.

*Botulism.*

Nowadays a good many different types of illness are being falsely labelled botulism, so it is useful to call attention to certain characteristic symptoms of this disease and distinguishing features of the bacillus in order to facilitate the early diagnosis of outbreaks and prevent cases of illness being brought forward as examples of botulism without reasonable probability. A provisional diagnosis of botulism must be based on symptoms and epidemiological factors; the conversion of a provisional into a definite diagnosis is the task of the bacteriologist. The characteristic symptoms of botulism are well known—eye disturbances, such as double vision; throat symptoms, such as difficulty in swallowing and talking; general muscular weakness. It is equally important to know the symptoms which do not occur—thus pain is absent, the cardinal symptoms of salmonella type of infection are not found, constipation rather than diarrhoea is the rule. Fever is rare. Mentality and consciousness are usually clear to the end.

Distinguishing epidemiological and technical points stressed by the report are that *B. botulinus* is an anaerobe, and the food vehicle must be such as will allow growth only in the absence of oxygen. *B. botulinus* is a proteolytic anaerobe, and will originate decomposition changes in the food if it multiplies sufficiently to yield toxin, a feature which distinguishes it from the behaviour of salmonella bacteria, which do not betray their presence by any evident decomposition. The physical condition of the food is therefore an important diagnostic point, but though the food is altered the changes may be slight, and only detected by an expert. Perhaps, as at Loch Maree, they may be missed altogether. Finally, it is important to remember that, owing to the high potency of *botulinus* toxin, nearly everyone who partakes of food infected with this organism becomes ill. To the salmonella type of infection some individuals are much more resistant than others, and may escape.

*Cheese Poisoning.*

Cheese poisoning has always been a puzzling disease. There were eight instances of it in the present series. The most characteristic symptom was abdominal pain, sometimes attended with vomiting, less frequently with diarrhoea. Everything pointed to the ingestion of a gastro-intestinal irritant. The incubation period in these 8 cases was about four to twelve hours, and the infectivity rate about 90 per cent. The cheeses appeared perfectly natural and wholesome, and the types of cheese responsible were not those in which secondary ripening changes of a decomposing nature were customary.

From the experimental work recorded in this report, particularly that in relation to outbreak No. 41, it seems almost

\* Medical Research Council, Special Report Series, No. 92, *Food Poisoning: A Study of 100 Recent Outbreaks*. By W. G. Savage, M.D., B.Sc., and P. Bruce White, B.Sc. Price 2s. 6d.

certain that the toxic agent must have been the product of bacterial activity. Orthodox opinion held formerly that a toxic substance known as tyrotoxin was responsible for cheese poisoning, but Dr. Savage and Mr. White looked for this substance in vain. They think that it may have been the cause of outbreaks in the past, but they note that there are few if any references to the finding of this body in poisonous cheese since the days when the ptomaine theory of food poisoning was abandoned, and conclude that tyrotoxin has no connexion with cheese poisoning as met with at present. Experiments reported by the authors demonstrate that some salmonella bacteria will survive for several weeks in cheese or acid whey, though they do not appear to multiply, but rather diminish, therein. Such infected cheese was not specifically toxic when fed to laboratory animals. Evidently the toxic agent in cheese poisoning may not have been the same in all cases, but probably the commonest cause was an undestroyed toxin of some special germ, and in some cases members of the salmonella group of bacteria were to blame.

#### *Paths of Infection.*

How does food become infected with poisonous bacteria? This is the vital question, but search for an answer has been hampered by insufficient material for analysis. More knowledge is needed of the primary reservoir of these bacteria, and practically nothing is known at present of the way in which they get into food. It is to be regretted that previous investigators for the most part have been content with mere evidence of excretal contamination of the food, not reflecting that the salmonella bacteria are not constituents of the normal excreta of man or animals.

Speaking of the primary reservoir of infection, Dr. Savage and Mr. White point to three possibilities. These germs may have a habitat outside the body, but there are no facts which suggest the likelihood of this. Again, infection may come from a human case, but such an origin is rarely suggested by epidemiological survey, and is rendered unlikely by the fact that sufferers from food poisoning disease do not excrete salmonella bacilli for more than a few days. Thirdly, infection may come from an animal source—either from the meat or milk of an infected animal being used for food, or due to infection of previously wholesome food with bacilli from an infected animal.

After considering the pros and cons of each of these the authors conclude that in the majority of the 100 outbreaks reported the food was originally sound, but became infected with salmonella bacteria from outside sources. The particular channel of contamination in most of the outbreaks remained undetermined.

This part of the report closes with a memorandum giving instructions as to the collection and transmission of samples for bacteriological and chemical analysis. The remaining fifty pages contain the detailed history of the 100 outbreaks of food poisoning on which this report is based.

#### ROYAL MEDICAL BENEVOLENT FUND.

At the last meeting of the Committee thirty-two cases were considered and £476 voted to thirty applicants. The following is a summary of some of the cases relieved.

Widow, aged 62, of L.S.A. who died in 1923. Applicant lets rooms to provide for herself and two daughters living at home. Her total income is £55 per annum, but a daughter who is a nursery governess pays her 10s. a week. Applicant asks for a grant towards 50 guineas per annum for a son who has been in Earlswood for seven years. Voted £20 in two instalments.

L.R.C.P. and S.I., 1879, aged 74. During the war was on sea transport. He received £52 10s. for acting as locum tenens during the last twelve months. Room, breakfast, and supper cost him £1 a week. Owing to influenza and phlebitis has not been able to pay his landlady, to whom he owes £28. Voted £30.

Daughter, aged 56, of M.R.C.S.Eng. who died in 1914. She is in ill health and has rheumatoid arthritis. Plain needlework brought her in £12, and she has £14 a year from War Loan and £5 from the National Benevolent Institution. Rent 3s. a week. The Fund local secretary says, "With the new occupiers." Voted £25 in twelve monthly instalments.

Widow, aged 49, of L.R.C.P. Edin. who died in October, 1924. She is left with three children aged 19, 12, and 10, and only £40 a year. The eldest son is a farm pupil and only receives pocket money; the other children are at school. Applicant wishes to sell out her capital and start a business, and asks the Fund to help her with the education of her two youngest children until she is established. Voted small grant and referred to the Guild.

Subscriptions may be sent to the Honorary Treasurer, Sir Charles Symonds, K.B.E., C.B., M.S., at 11, Chandos Street, Cavendish Square, W.1.

## England and Wales.

### REBUILDING THE MIDDLESEX HOSPITAL.

It has been decided to rebuild on the present site, at a cost of £500,000, the main portion of the Middlesex Hospital, including the east and west wings, the connecting block, and the old houses in which many of the nurses are accommodated. The present buildings, erected between 1756 and 1780, replacing a smaller hospital opened in 1745, have become seriously damaged in consequence of the lapse of time and faults inherent in their structure. The foundations extend only three or four inches below the level of the area, the floors are full of dry rot, and the ceilings are cracking. Moreover, in spite of the many extensions that have been made, the facilities that were adequate for the 102 in-patients of the first recorded year, 1746-47, are now unequal to the demands of the special departments and the additional work consequent on the triumphs of medical research with which the Middlesex Hospital has been so frequently associated. The cancer department of the hospital is one of the portions that will remain untouched under the reconstruction scheme, but greater accommodation is required for the in-patients associated with the special departments, such as the aural, neurological, and radiological, and also for the medical school. During each year some 6,000 in-patients receive treatment, and yet there is always a long waiting list; in the out-patient department seven and a half million attendances have been registered since the foundation of the hospital. The approval of representatives of the King Edward Hospital Fund has been obtained for the rebuilding, and arrangements are being made so that during the work the in-patient accommodation shall not be reduced by a single bed. The existing site of the building presents several advantages; the land on which it stands is held at a nominal rent through the generosity of the Berners family, and the hospital serves a district containing one and a half million workers. In close association with it are the more modern buildings, including the cancer wing, the research department, the x-ray and physical medicine section, and the medical school. Temporary steps already taken to avert any danger include the closing of two wards, and the strutting of the basement and of fourteen wards with heavy baulks of timber. All the old buildings will be demolished as soon as accommodation for the patients can be found. The rebuilding of the hospital is a matter of necessity, not of choice, since the condemned blocks have deteriorated too far for less radical treatment to be possible.

### TUBERCULOSIS ARRANGEMENTS IN LONDON.

A report on tuberculosis arrangements in London was submitted to the London County Council by its Public Health Committee on May 5th. For the year 1925-26 provision has been made for 1,793 beds for adult cases; of these, 1,019 will be available in the institutions of the Metropolitan Asylums Board and 774 in voluntary institutions. Twenty beds have been taken at Burrow Hill Colony for cases specially selected for extended sanatorium treatment. Grove Park Hospital is being prepared for the reception of adult advanced cases, and it is expected that arrangements will be completed at an early date. The provision for children comprises 800 beds, of which 590 are in the institutions of the Metropolitan Asylums Board. Six beds have been taken at the New End Hospital, Hampstead, for artificial light treatment of specially selected cases, and the Public Health Committee is considering the question of providing for a large-scale test of artificial light treatment. The dispensary service now includes twenty-one municipal dispensaries, one voluntary dispensary largely aided by a borough council, and nine dispensaries, also aided by borough councils, at hospitals. The history of 3,060 adult patients under treatment during 1921 has been ascertained. The records up to July, 1924 (that is, two and a half to three years after completion of residential treatment), showed that among 512 cases in which bacilli had been absent from the sputum, 91.2 per cent. were alive; out of 344 cases in which, although bacilli were found in the sputum, there was only slight constitutional disturbance;

and in which the obvious signs were of very limited extent, 78.2 per cent. were alive; of 858 cases with profound systemic disturbance or constitutional deterioration, or with grave complications, 9.2 per cent. were alive, and of 1,346 cases which fell somewhere between these last two groups 51.7 per cent. were alive. The committee is not satisfied as to the number of early cases coming under treatment, and is investigating the possibility of obtaining earlier notification. The arrangements for children include five special open-air schools, accommodating 365 children, and it is intended to increase this provision. The committee quotes mortality figures which reflect the success of the co-ordinated efforts of public authorities and voluntary agencies. During the year 1923 the deaths from tuberculosis in London numbered 5,285, the lowest number hitherto recorded, and 439 below the previous year.

#### ESSEX COUNTY HOSPITAL, COLCHESTER.

During the past year there has been a considerable increase in both the number of in-patients and out-patients at the Essex County Hospital, Colchester, and, though the ordinary income rose by about £1,500, a deficit of £2,844 resulted from the year's working. A contributory scheme for workers and their families has been launched in the country districts served by the hospital, and after being in operation for three months has produced gratifying results. It is expected that during the current year very substantial help will be received from this source. Valuable support has been given also by the Colchester and District Workers' Committee. A serious shortage of accommodation is handicapping the work in both the in-patient and the out-patient departments, and the nursing staff is restricted similarly. The new out-patient block is nearing completion, and twelve new wards for private patients will also become available, reducing somewhat the pressure on the general surgical wards. A fund has been opened for the erection of a new nurses' home.

#### SIR MALCOLM MORRIS MEMORIAL.

The fund inaugurated a year ago to perpetuate the public services of the late Sir Malcolm Alexander Morris, K.C.V.O., F.R.C.S.Ed., has now been closed, and the committee, representative of the various organizations and institutions with which he was intimately associated, has allocated the money raised in providing a prize at St. Mary's Hospital, Paddington, to the final year's student best qualified in dermatology, and in endowing a public lectureship under the Chadwick Trust upon the preventive aspects of public health and upon dermatology in alternate years.

## Scotland.

#### INAUGURAL LECTURE IN THERAPEUTICS.

PROFESSOR LONRAIN SMITH, Dean of the Edinburgh Faculty of Medicine, presided at Professor D. M. Lyon's inaugural lecture on the development of therapeutics. The lecturer said that it was interesting to recognize traces of long-discredited theories in the medical teaching of to-day. The primitive mind had recognized three views as to the cause of disease—the religious view that disease was due to some spiritual tendency, the magical view that disease was due to the action of some human agent, and the natural view that disease was due to simple natural causes. The primitive savage often regarded disease as a material thing which could be magically transferred into a victim's body from a distance, and a strong strain of magic was still to be found in the belief of the lay community. During the four centuries since the Renaissance authority had been suspect and traditional reputations had been submitted to close scrutiny. It seemed highly probable, therefore, that there must be some virtue in drugs recommended by successive generations of trained observers. Many laymen apparently believed that for each ailment there existed a satisfactory combination of drugs and that no proper treatment was possible without the inevitable "bottle." Modern practice, however, was tending to give drug therapy its

proper place in treatment. Many other remedial measures were now in use, such as by thyroid and adrenaline extracts, antitoxic serums for diphtheria and tetanus, and appropriate vaccines for the prophylaxis and treatment of the enteric group of diseases. Massage and remedial exercises were now extensively used, and radium emanations, Roentgen rays and electricity, the ultra-violet rays, Finsen light, and heliotherapy had all been pressed into the service of treatment. Psychotherapy was a recognized branch of comparatively recent introduction, and, divorced from the showy tricks of hypnotism and mesmerism, it had taken its legitimate position in treatment. The number of true curative specifics was limited, but other drugs, though not leading to cure, possessed definite actions in restoring health, such as thyroxin in myxoedema and insulin in diabetes, and such drugs as digitalis in heart failure and adrenaline in asthma were extremely valuable. A certain number of diseases were still beyond assistance, and the patient medicine vendor was alive to the limitations of the healing art. Though for the most part the ingredients of proprietary medicines were drugs employed in legitimate medicine or rejected by the profession as useless, the danger associated with such practices was real, so that it was time that the public took steps to control this trade.

#### EDINBURGH MATERNITY HOSPITAL NEEDS.

Dr. William Robertson, medical officer of health for Edinburgh, who presided over the annual meeting of subscribers to the Edinburgh Royal Maternity and Simpson Memorial Hospital, said that the total number of cases treated during last year had been 92 fewer than in the previous year, which had shown the highest record in the history of the institution. Out of over 9,000 births during the year in Edinburgh, fully 3,000 were attended at the Simpson Memorial Hospital. It thus did excellent humanitarian service, but it also did work of great preventive and educational value, and the city was under a deep debt of gratitude to it for the knowledge disseminated by its medical and nursing staff. He hoped shortly to see a great extension of maternity and child welfare work in connexion with the hospital. The fact that Edinburgh was a great centre of medical education must not be lost sight of, and for this purpose more accommodation was required in the Maternity Hospital. The Rotunda Hospital of Dublin had for long possessed a magnetic attraction for students of medicine, and an enlarged maternity hospital in Edinburgh would exercise an equal attraction. As long ago as November, 1923, the directors had made suggestions to the managers of the Edinburgh Royal Infirmary as to a suitable site for a new maternity hospital, and as to the form and extent of the desired affiliation between the two institutions. Dr. T. G. Nasmyth said that the infirmary managers were negotiating with the Merchant Company to get part of the site of George Watson's College, and they had addressed to the secretary of the Maternity Hospital recently a letter saying that, looking to their further needs, they might not be able to give the Maternity Hospital any part of the site. This was disappointing. The financial statement showed a shortage of £1,094, as against £726 last year.

#### DR. DAWSON TURNER.

At a meeting of the managers of the Edinburgh Royal Infirmary, held on April 27th, Lord Provost W. L. Sleigh presiding, the retirement of Dr. Dawson Turner on account of ill health from the post of extra medical electrician was intimated. The board placed on record its appreciation of the services rendered to the Royal Infirmary by Dr. Dawson Turner for a period of twenty-nine years. He had been appointed assistant medical officer to the medical electrical department in 1896, and promoted to full charge of the department in 1901. After ten years spent in the practice of radiology he became extra medical electrician, and in 1914, at his own request, in view of the deleterious effect of x rays upon his system, his charge was restricted to the care of cases requiring radium alone, and he had continued to hold this special appointment to the present time. The board further expressed its obligation to Dr. Turner for his generosity in employing his own stock of

radium from time to time to supplement the quantity owned by the Royal Infirmary; and invited him to continue his association with the institution as honorary consulting physician in radiology.

#### NEW SCHEME FOR FALKIRK INFIRMARY.

A meeting was held in the Town Hall, Falkirk, on April 27th to start a campaign for the collection of £50,000 towards the erection of a new infirmary for Falkirk and district. Provost Muirhead presided over a large gathering, which included representatives from other burghs in the district. The Marquess of Louthgow stated that the scheme would cost the district approximately £100,000, but almost one-half of that had either been already subscribed or was in sight. The present infirmary had begun in a small way in 1889 as a cottage hospital of 14 beds, and had gradually been increased decade by decade until in 1920 it had been decided to alter its name to the Falkirk and District Infirmary, because for some time and in an increasing degree the institution had been serving a wider area than Falkirk itself. The accepted proportion of beds to population in these days was about 2 per 1,000, so that with a population of 100,000 in the area there should be 200 beds instead of the 74 in the existing infirmary. Institutional treatment would increase in importance as time went on, and it was to be expected that the population of the district would grow year by year. The infirmary had no pathological laboratory because there was no room for it, and the time had now come when it was necessary to proceed with a building scheme. A site of 11½ acres had been purchased on the estate of Gartcows, which would allow for future extension. The voluntary principle provided the zeal, elasticity, and adaptability that came from the absence of control from a distance and from eager people giving voluntary services. The governing body of the infirmary depended for money to carry on its operations upon the contributions of no fewer than 25,000 wage earners in the district, who were adequately represented on the governing body, and that was a guarantee against any too close a corporation in the management of the infirmary. The present appeal was an appeal to local patriotism, and he did not think that £50,000 was beyond the measure of those who had been brought up on Stirling Brig, Falkirk, and Bannockburn. Sir Norman Walker said that the committee appointed by the Scottish Board of Health had had no difficulty in satisfying itself that the supply of hospitals in Scotland was inadequate; a hundred years ago there were about 6 hospitals in Scotland, while to-day there were 286, and of these 132 were voluntary. It was possible to supply the needed beds in two ways—either by increasing the number of beds in the hospitals of the large centres, or, as Falkirk proposed, by developing the local hospital into a really efficient general hospital for the district. He knew that there was no place where rich and poor could be better looked after than in one of the general hospitals, and if persons were dying they would, of course, be taken into these hospitals, but the same ready admission could not at present be promised to persons suffering from some malady which was hampering their usefulness. For this reason he welcomed an increase of hospitals such as that at Falkirk.

### Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

THE House of Commons has this week passed the Gold Standard Bill through all its stages and has taken the report of the Budget resolutions imposing taxation. It has also passed the Rent Restriction Bill through report and third reading after a debate, in which Dr. Fremantle took part. The Moneylenders Bill has been read a second time and sent to the Committee of both Houses, and the Advertisements Regulation Bill, which has come down from the Lords, has been sent to a Grand Committee. The Therapeutical Substances Bill was down for second reading on May 5th, but was put back. Bills such as this may have to be postponed owing to the introduction of the Widows, Orphans, and Old Age Contributory Pensions Bill, which will require much time for discussion. In particular,

the Government does not expect this session to get the Factories Bill beyond the second reading, nor to pass the Rating and Valuation Bill, which is regarded as a necessary preliminary to a general measure of Poor Law reform. Mr. A. V. Alexander, having won first place in the ballot for private members' motions on May 27th, has given notice that he will call attention to the overlapping and duplication of services and establishment due to the existence in England and Wales of rival local authorities dealing with the children, the sick and infirm, the aged, and the able-bodied unemployed.

The text of the Widows, Orphans, and Old Age Contributory Pensions Bill was issued on May 5th, with an accompanying memorandum and actuarial statement, but a fortnight was promised for its examination before second reading. The bill follows the lines sketched out by the Chancellor of the Exchequer when introducing the Bridget, and comprises forty-five clauses. The provisions for pensions to widows and orphans would come into force from January 4th, 1926; those for the removal of the means limits on old age pensions drawn by persons over 70 on July 2nd, 1926, and for old age pensions at 65 on January 2nd, 1928. As a result of the reduction of the health insurance maximum age from 70 to 65, the health insurance contribution is being reduced by a penny a week for a man and by a halfpenny for a woman. But the actuarial memorandum explains that though the right to sickness and disablement benefits will cease at 65, when the new pensions accrue, the proposals in the bill make no alteration in the existing right of an insured person to receive medical benefit for the whole of life.

#### Small-pox.

Sir William Davison asked the Minister of Health, on May 5th, whether his attention had been called to the recent increase in cases of small-pox throughout the country; what was the total number of cases notified during the past three months; and whether he had received any report on the courses which had brought about the recent increase in such cases.

Sir Kingsley Wood said that the total number of cases of small-pox notified in England and Wales during the twelve weeks from January 4th to March 28th was 1,609. The Minister of Health had received numerous reports made by medical officers of the Department who had visited the districts in which small-pox was prevalent, and he was advised that the recent increase in the number of cases might be attributed to the neglect of vaccination in many of the invaded districts, and to neglect of the precautions which were essential if the spread of the disease was to be checked. He took this opportunity of informing the House and the country that Mr. Chamberlain was advised that there was no doubt the disease, now so prevalent in certain districts, was true small-pox, though happily mild in degree, and that vaccination was the only reliable protection against it. (This statement was greeted with protests from the Labour benches.)

Sir William Davison asked whether it was a fact that the late Minister of Health issued an Order making it easier for people to obtain exemption from vaccination. (Labour cheers.) Dr. Watts asked whether each of these cases cost the local authority £250 for treatment, isolation, disinfection, and so forth; and whether the Minister's attention had been drawn to the report of a medical officer of health that in his area the money spent on these cases could have built 1,000 or 1,500 houses. Mr. N. McLean asked if the Government would issue orders to the local authorities to extend the building of houses and the clearing of sites, and to take steps to eliminate this disease by means of fresh air and pure food and not by vaccination.

Sir Victor Warrender asked whether the incidence of the disease had increased since the coming into effect of the present regulations affecting exemption from vaccination.

Sir Kingsley Wood presumed that Sir Victor Warrender referred to the Order issued by the late Minister of Health, which had the effect of reversing an Order issued by Mr. Neville Chamberlain on July 20th, 1923, and of reinserting in the form of statutory declaration of conscientious objection in the notice of the requirement of vaccination handed to the parent or guardian when the birth of a child was registered. The Order of the late Minister came into force on October 1st last, and Mr. Chamberlain was watching its effect, but there was not yet sufficient evidence to enable him to form a final opinion on it.

Dr. Watts asked how Sir Kingsley Wood explained the fact that, despite the number of cases of small-pox, proceedings were rarely, if ever, instituted under the present Vaccination Act. Sir Kingsley Wood asked for notice of that question. Dr. Fremantle asked whether the Government was considering the transference of these powers from the boards of guardians to the sanitary authorities, so that they might be worked out in common with the general upkeep of the public health. No reply was given to this question.

**Vaccination as Condition of Employment.**—Mr. Clowes asked the Minister of Labour, on May 4th, whether he was aware that at the instance of Messrs. Brunner, Mond and Co., an application for bricklayers between the ages of 26 and 40, who must be willing to be vaccinated, or had recently been vaccinated; whether it was in accordance with regular practice for applications of this nature to be posted at employment exchanges; and whether an unemployed bricklayer who refused an offer of employment under such conditions would be disqualified for benefit. Mr. Betterton (Parliamentary Secretary to the Ministry of Labour) replied that he had not yet completed his inquiries into this case. It was the ordinary practice to post up in the exchange notices of vacancies which could not be immediately filled from the registers. The question whether benefit would be disallowed on refusal of vacancies of this kind would be determined by the usual statutory machinery.

**School Children and Infection.**—Colonel Day asked the Minister of Health, on May 5th, if he would consider the introduction of legislation to prevent persons in control of children, as, for example, headmasters and managers of schools, from permitting them when in an infectious condition to enter public vehicles or go into public places at the risk of spreading infection. Sir Kingsley Wood said provision was already made in Section 126 of the Public Health Act, 1875, for preventing the exposure, without proper precautions, in public places and public conveyances of children suffering from any dangerous infectious disorder. Similar provisions as regards London were contained in Sections 68 and 70 of the Public Health (London) Act, 1891, and there were numerous supplementary provisions on this subject contained in local Acts. The question of introducing further legislation dealing generally with the matter would be considered in connexion with the proposed amendment of the Public Health Acts.

**Cost of Child Welfare and Maternity Clinics.**—Mr. Lansbury asked the Minister of Health, on May 5th, the amount of public money spent by local authorities during the years ending March, 1913, and March, 1925, on child welfare clinics and other centres, and on the supply of milk to nursing and expectant mothers, during the same period, showing the sum raised from the rates and that paid from the National Exchequer. Sir Kingsley Wood, in reply, said no figures were available as regards mothers' child welfare services in respect of the year ended March, 1913, year ended March 31st, 1915, being the first in respect of which an Exchequer grant was paid on these services. The total net expenditure of local authorities in England and Wales on all maternity and child welfare services in that year was (approximately) £66,700, and of voluntary agencies receiving the Exchequer grant (approximately) £16,200. No separate figures on the expenditure of local authorities on maternity and child welfare centres and clinics, or on the supply of milk to nursing and expectant mothers and children, were available prior to the year ended March, 1920. For that year the net expenditure was: maternity and child welfare centres and clinics, £132,379 (exclusive of the cost of medical supervision and services of health visitors, which could not be given separately in respect of health visitors, of the voluntary agencies receiving Exchequer grants in that year was approximately £102,000. Particulars of the actual expenditure on these services for the year ended March, 1924, was: maternity and child welfare centres and clinics, £134,340 (exclusive of medical supervision and health visitors services); supply of milk and food to nursing and expectant mothers and to children, £200,100; centres and clinics provided by voluntary agencies receiving Exchequer grant (approximately), £105,100. One-half of this expenditure was met by way of Exchequer grant, and one-half of the net expenditure of local authorities was met out of the rates.

**Dried Milk.**—Mr. Groves (Stratford) asked whether the reduction in the infantile death rate in West Ham had not proceeded side by side with the increased supply of dried milk and the general development of the borough health services; and whether the Ministry of Health would recommend the local authorities of the country to use dried milk in preference to liquid milk. The Parliamentary Secretary to the Ministry of Health replied that the reduction in the infantile mortality of West Ham was comparable to that in other areas and could not be attributed exclusively to any particular measures made in the West Ham area. The Ministry was not prepared to make the recommendation suggested.

**Necropsies in Criminal Cases.**—Mr. A. R. Kennedy asked the Home Secretary, on May 4th, if he were aware of the disadvantage which might attach to a person accused of murder or manslaughter in the conduct of his defence from the practice of appointing one medical man only to conduct a *post-mortem* examination, and whether he would take the necessary steps to ensure that, where a person had died in circumstances which might lead to a criminal charge against another, and a *post-mortem* examination was held, a fully qualified medical practitioner should be appointed to watch the examination in the interests of the person, if any, thereafter to be charged. The Under Secretary for Home Affairs replied that the Home Secretary did not see his way to propose legislation for this purpose. A *post-mortem* examination was not a matter of advocacy but of scientific investigation. The Director of Public Prosecutions was, however, considering whether it might not be possible to arrange that the defence should have the opportunity of appointing a medical man to be present on behalf of the defendant when the *post-mortem* examination was performed.

**Pensions.**—The Minister of Pensions has made the following replies to various questions: (1) Where an applicant's appeal had been rejected or a final appeal had been confirmed the decision was final, but if fresh evidence was subsequently produced which clearly showed that the disability or death was due to war service, an award was made. In cases of final award where, in the course of medical treatment and observation by the Ministry, it was clearly demonstrated to the Ministry that the award had been wrongly declared final owing to error of diagnosis or prognosis involving a serious underestimate of the degree of permanent disablement, the award was reviewed and a further grant made. (2) Steps have recently been taken to secure that the speediest decision possible is reached in cases outstanding before medical boards. The cases were as a whole decided far more rapidly than a short time ago. (3) That during the year ended March 31st, 1925, about 50,000 fresh claims were decided by the Pensions Ministry, and some 17,000 awards were made, of which 11,500 were to persons not previously in receipt of pensions. The Pensions Appeal Tribunals heard 46,570 appeals in the same time, and disallowed 24,500. At March 31st the beneficiaries under the Pensions Acts numbered 2,037,000, compared with 3,366,000 in March, 1921.

**Lead Paint Bill.**—The Lead Paint (Protection against Poisoning) Bill, to make better provision for the protection against lead poisoning of persons employed in painting buildings, was introduced into the House of Commons by the Home Secretary on May 1st, and was read a first time.

**The Indian Services.**—Earl Winterton, Under Secretary for India, stated, on May 4th, that the recommendations of the Lec Commission Report on pay and passage have been extended to members of the fifteen central services, which it had been decided to regard as superior, in precisely the same way as they had been given to members of the All-India services, other than the Indian Civil Service. Eligibility for these concessions depended upon an officer having a non-Asiatic domicile. The pension concessions had also been given to thirteen of these fifteen services.

**Notes in Brief.**  
The additional excise duties on proprietary medicines which were imposed by the Finance Act of 1915 have been continued as part of the new Budget, by resolution of the House of Commons under the Provisional Collection of Taxes Act.  
The number of accidents during 1924 caused by passengers falling out of moving railway carriages was 75. Of these, 30 were fatal.  
The Advisory Committee on Opium Traffic, which advises the Council of the League of Nations on the supervision of the traffic, will meet some time before September. It is not proposed to lay before Parliament at this stage the protocol drawn up by the recent Opium Conference at Geneva.  
The Ministry of Health is unable to say when the report of the Royal Commission on National Health Insurance will be presented to Parliament.

## Correspondence.

**THE DECLINE OF LITHOLAPAXY.**  
Sir,—Major-General A. Hooton's interesting paper on the decline of litholapaxy (BRITISH MEDICAL JOURNAL, April 11th, p. 690) prompted us to look up the statistics of cases of stone admitted into St. Peter's Hospital, London. We find that out of 371 consecutive cases of vesical calculus recently admitted to the wards, litholapaxy was performed on 226, suprapubic lithotomy on 144, and perineal lithotomy on one.

At first sight these figures appear to confirm the impression that the operation of litholapaxy is declining in frequency, but further investigation shows that this is not the case. We found that in 79 of the 144 cases on which suprapubic lithotomy was performed some form of prostatic obstruction was also present, which necessitated an open operation. Sixty-nine of these cases were simple scute vesical diverticulum and 2 by urethral stricture. Five of the remaining 10 cases were cases of obstruction recurring after prostatectomy, while the last case was one of obstruction caused by a prostatic bar. There were also 14 cases in which litholapaxy was contraindicated by reason of some vesical condition. These were diverticulum (9 cases), diverticulum carcinoma (2 cases), vesical carcinoma, recto-vesical fistula resulting from a rectal carcinoma, and prolapse of the nreter. One case was associated with an impassable stricture of the urethra. This leaves 50 cases to be accounted for. In 8 of these the stone was too large to be crushed, 3 were vesico-urethral calculi, one stone was adherent to the bladder wall, one formed round a drainage tube left in the bladder after a previous operation, and one was found

on opening the bladder to deviate the urine prior to an operation for hypospadias. There were 4 cases in which litholapaxy failed. In one of these the stone was composed of fibri covered by a thin layer of phosphates; in another the patient was suffering from advanced tabes, and, although the stone was easily crushed, the fragments could not be evacuated. The bladder was opened, and it was found that they had slipped through the relaxed sphincter vesicae into the posterior urethra. In the remaining 2 cases the cause of the failure was not mentioned. In 31 cases no definite reason was given in the notes why lithotomy was performed instead of litholapaxy, but in all these cases foul cystitis was present, and it is probable that the bladder was opened in order to relieve the infection.

The one case of perineal lithotomy was of interest. The patient had stones in both kidneys, in the right ureter, in the bladder, and in the urethra. As the urethral calculus could not be displaced back into the bladder, external urethrotomy was performed, and the bladder stones were removed at the same time through the urethral incision.

From these figures it will be seen that litholapaxy is still considered the operation of choice for uncomplicated vesical calculus, and that the surgical staff of the hospital only resort to lithotomy when there is a definite contraindication to the crushing operation. In one sense only has the operation declined. Before the introduction of prostatectomy, litholapaxy was considered to be the correct treatment of stone complicating prostatic obstruction. The results in these cases were very bad, as it was practically impossible to evacuate fragments which had fallen into the post-prostatic pouch, and recurrence was the rule and not the exception. No recurrence due to imperfect evacuation of the fragments has been noted in the present series of 226 operations, and the mortality is only 2.2 per cent., so that the end-results are eminently satisfactory.—We are, etc.,

J. SWIFT JOLY.

J. ALBAN ANDREWS.

London, W.1, May 4th.

### THE EFFECT OF ANTISYPHILITIC TREATMENT AS GAUGED BY THE SIGMA REACTION.

SIR,—Table I in the paper on this subject by Dr. P. H. Jones, which appears in the *JOURNAL* of May 2nd (p. 821), conveys an impression of the Wassermann and Sigma results obtained by one of us (E. J. W.) which is entirely erroneous. Under the columns headed "Controls" appear 14 Wassermann and 20 Sigma positive reactions. The 20 Sigma reactions are qualified by a note to the effect that 11 of these cases were later diagnosed as syphilis, leaving the impression that the Wassermann test gave 14 non-specific reactions and the Sigma 9. Reference to the report from which Dr. Jones quoted<sup>1</sup> will show that, of the 14 results classed by him as positive, 5 were doubtful reactions, which we are always careful to say should never be regarded as positive in unknown cases. The remaining 9 cases gave positive reactions also to the Sigma, Sachs-Georgi, and Meinicke tests, and, incidentally, positive Wassermann reactions in another laboratory. The reactions were strong ones and indicate that, although counted under "controls" (since no clinical signs or history of syphilis had been discovered at the time of reporting), they were in fact syphilitic.

Of the 20 Sigma results, 3 were reported as doubtful and should not be classed as positive, and 9 have been explained above. As to the remainder, we may not trespass so much on your space as would be necessary to explain them in detail, and must content ourselves with referring to the report made to the Copenhagen Conference in November to December, 1923.<sup>2</sup> In this we mentioned that further investigation had made it necessary to revise some of the diagnoses shown in the first report (from which Dr. Jones has quoted), with the result that, in a total of 2,240 serums (1,701 syphilitic and 539 probably non-syphilitic) which had been tested up to the time of the Conference, the Wassermann test had afforded us no non-specific results and the Sigma only one, a reaction of 1.6 units. At the Technical

Laboratory Conference in Copenhagen, to the report on which we have referred, eight serums described as "controls" were found by those of the eight representatives of European laboratories who tested them to be positive by the Wassermann, Sachs-Georgi, Sigma, Meinicke III, and Meinicke Trübungs methods, showing that they were in fact syphilitic. With these exceptions, neither the Wassermann nor the Sigma test gave, in our hands, a positive reaction in a control case.—We are, etc.,

I. W. HARRISON.

E. J. WYLEN.

St. Thomas's Hospital, May 2nd.

### DERMATITIS FOLLOWING ULTRA-VIOLET LIGHT.

SIR,—While Mr. W. E. Schall (April 25th, p. 806) is correct in his comparison of the physical properties of sunlight and radiation from the mercury vapour lamp, I would like to point out that he is not correct in his conclusion as to the clinical effect of the mercury vapour lamp.

The shorter wave ultra-violet rays which this lamp produces—that is to say, rays of a wave-length between 3,000 and 2,000 A.U.—should give a slight erythema (when a properly regulated dose is given) at first, but after a few treatments the skin becomes tolerant and is not inflamed by these rays. I have not been able to detect any harm from their use, and their presence in the radiation of the mercury vapour lamp is, in my opinion, no reason why it should not be used. I find that in skilled hands the mercury vapour lamp, used in conjunction with other lamps to produce the longer rays, gives far better results when used for the general irradiation of the normal skin than the open carbon arc lamp, and never produces chronic dermatitis.

The case described by Drs. MacCormac and Moreland McCrea, in which an old gentleman went to sleep under the mercury vapour lamp with which he was treating himself, can surely have no bearing on the question at all, because you might as well say that one should never have a hot bath because someone had once fallen into a boiler.—I am, etc.,

London, W.1, May 3rd.

G. MORRAT LEVICK.

SIR,—In your issue of April 25th (p. 806) Mr. Schall, B.Sc., points to the use of the mercury vapour lamp, with its intenser radiation of ultra-violet rays in the region of 300 to 200  $\mu\mu$ , as having caused the severe attack of dermatitis recently reported in your columns. Mr. Schall advocates the use of a carbon arc lamp as a superior instrument for general irradiation because its spectrum more closely resembles that of the sun, and he would reserve the mercury vapour lamp for the treatment of cases of a more definitely surgical nature.

I hold no brief for the mercury vapour lamp, and use both it and the carbon arc, but the experience of several years of ultra-violet and light therapy has brought me to just the opposite conclusion to Mr. Schall. First of all, no one dreams of employing the mercury vapour lamp alone except perhaps in certain cases of dermatitis. In all general irradiation its cold ultra-violet rays must be supplemented by the longer infra-red and red rays of a lamp of the Sollux or some other type of thermic lamp. This, in my opinion, is more efficiently done by the combination of two lamps, which makes it possible to modify and adapt treatment to individual cases much better than is possible when both ultra-violet and thermic rays come from one unvarying source.

It is this adaptability and variety that makes the mercury vapour lamp such a valuable instrument in general irradiation. By increasing or decreasing the distance of one or other lamp the intensity of actinic and thermic rays can be altered, while by the skilful use of "ulviol" filters the shortest ultra-violet rays can be excluded altogether if necessary, and the patient can very quickly be brought up to the ideal maximum (half an hour's unfiltered quartz light daily) without fear of too strong reaction, and this with a very small expenditure of current. The carbon arc, on the other hand, requires a very large amount of current, and general treatments are very much longer.

of the Technical  
November 19th to December

Its use is therefore much more expensive, and it has minor drawbacks, such as flickering and sputtering, the handling of dirty carbons, and the fact that the air of the room is soon vitiated by fumes of nitrous oxide and carbon dioxide.

But in the treatment of local conditions, particularly in surgical tuberculosis and lupus, it is far superior to the mercury vapour lamp, which is only effective in superficial forms of lupus. In chronic cases with deep indurations and infiltrations we need the greater penetration of the carbon arc to get the results which Doutrelepon has so well described as

"an inflammatory process involving the whole of the cutis with serous and fibrinous exudate from the dilated vessels and migration of leucocytes to surround and penetrate the tuberculous foci. A further stage is the vacuolar degeneration of the cellular elements of the tubercle and their ultimate replacement by spindle cells. Thus the lupus scar is formed."

St. Mary's Hospital, London.

April 29th.

### THE IMMEDIATE AND REMOTE EFFECTS OF SUNLIGHT.

SIR,—Supplementing the note of warning by Sir Lenthal Cheate and Dr. Heald (*JOURNAL*, March 28th, p. 631, and April 11th, p. 717) I would like to add a further note of warning—namely, that a method of treatment apparently so valuable should not be discarded as a remedial agent for lung tuberculosis before it has been fully and fairly tried.

This treatment has been in use at Stannington Children's Sanatorium for the last five years. Both medical and surgical cases have been dealt with. The tungsten arc lamp was installed in 1919, and the mercury vapour lamp (Hanan "mountain sun lamp") in August last. With regard to the surgical cases, our surgeon, Mr. H. M. Johnston, has had results as encouraging as those obtained by other workers who have recorded their experiences in the medical literature, although the results reported so optimistically in the lay press have not been obtained here.

With the medical cases we have naturally proceeded with the utmost caution, and although we have not attained the striking results recorded in surgical cases we have been emboldened to go on. Only in one instance do we suspect that the treatment may have done harm. This was a very chronic and severe case, in a girl aged 16 years, who was obviously going downhill. Realizing, however, that tuberculous patients may get a recrudescence, sunlight or no, we resumed treatment when the acute symptoms had to some extent abated, and carefully increased the dose. The results now have certainly been beneficial.

Reference was also made to Sir Henry Gauvain's opinion, that there is no definite correlation between bronzing of the skin and satisfactory clinical results. As one who has the pleasantest recollections of Sir Henry's discourse on heliotherapy, I must, however, beg leave to differ from him on this matter. Of natural sunshine, I have of necessity, in the North, no useful experience. Summer sunshine is so limited that it is impossible to acclimatize the patients to it gradually, and evil from overdosage is just as likely to accrue as good. I have however had, at Davos Platz, considerable experience through several winters of the effects of direct sunlight on lung cases, and while I agree that bronzing *per se* is no criterion, the quality of the bronzing is a very distinct indication of the prognosis of the case. A patient who is doing well maintains a pleasing, sometimes ruddy glow, while a retrogressive case will exhibit a sickly, yellowish, even jaundiced hue, or else no coloration at all. This distinction is patent to a layman.

In conclusion, while my treatment has been only tentative, I have had cases which have encouraged me to continue, but if this treatment is to go on—and there are signs that there will be lavish expenditure all over the country—I would urge that suitable light, airy, roomy buildings should be erected, as it is obvious that for both surgical and medical cases, but especially the latter, more

harm than good will accrue from the huddling together of numerous patients in a confined space, polluted by human emanations.—I am, etc.,

Morpeth, Northumberland,  
May 2nd.

T. C. HUNTER, M.D.,  
Medical Superintendent,  
Stannington Sanatorium.

Dr. R. KING BROWN (M.O.H. Bermondsey), after reading Sir G. Lenthal Cheate's letter, forwarded a copy to Dr. Axel Royn, chief physician at the Finsen Light Institute, Copenhagen, who has written the following note for publication:

I have read with the greatest interest Sir G. Lenthal Cheate's letter in the *BRITISH MEDICAL JOURNAL* of March 28th, in which he states that, with Dr. Arthur Whitfield, he has examined skin that had been "bronzed" by therapeutic exposure to sunlight and has found mitosis occurring in the epithelial cells situated above the basal layer, from which he seems to conclude that with the use of sunlight—or artificial irradiation—there may be connected a risk of inducing epithelioma. It is true that atrophic changes are sometimes observed in the skin of persons whose hands and face are habitually exposed to strong light and air, and that in such cases epithelioma is sometimes seen to develop there. But up to the present nothing has been brought forward to prove that it is the light, particularly, that produces these changes. From all indications they are due fully as much—or chiefly, rather—to such other influences as wind and rain and all the various assaults to which the constantly uncovered and unprotected skin of these persons is daily exposed. Do we not see epitheliomata of the skin develop in almost any site exposed to constant mechanical influences? We need only think of cancer of the lips, chimney-sweep's cancer, tar cancer, and many others. That the therapeutic application of light should produce epithelioma is in the highest degree unlikely. Nothing argues more strongly against this suggestion than the fact that up to this day no case of cancer of the skin has been reported as caused by the light bath, among the hundreds of thousands of persons who take either sun or artificial baths of this kind. And I may state, further, that among the thousands of patients who have received local phototherapeutic treatment for lupus at the Finsen Institute, we have not observed one case of lupous carcinoma resulting from this treatment. On the contrary, the percentage of lupous carcinoma shown by our records is the lowest existing, a fact which must be ascribed exclusively to the phototherapeutic treatment, which cures the patients so that they do not get carcinoma, while, if the light were particularly provocative in this respect, we should, of course, see a great many cases of this complication.

Of the fact that the phototherapeutic treatment does not produce epithelioma I see another proof in the conclusions arrived at by Dr. K. A. Heiberg, the histologist of the Finsen Institute, as the result of microscopical examinations made of the skin of twenty-five patients who had been under treatment with carbon arc light baths for a considerable period. Not in one single instance did Dr. Heiberg observe any change involving a risk of epithelioma; on the contrary, he proved that there takes place a vigorous regeneration of healthy skin, which greatly assists in improving the functioning of the latter. I therefore urgently recommend the use of light baths—sunlight or artificial—in all diseases for which this treatment is suitable. It is a therapy which has already proved so rich in beneficial results that it should be used, also in the future, to an ever-increasing extent; and we certainly must not allow ourselves to become frightened at dangers that are non-existent.

Dr. R. King Brown wrote also to Dr. Rollier of Leysin, who replied to somewhat the same effect.

Dr. Rollier considers that to obtain complete and well balanced therapeutic action a complex of rays should be used, the proportion of which is given by the solar light. They produce an increase of all vital phenomena in the skin, and it is therefore not extraordinary that the generative layers of epidermis should present more numerous mitoses. Dr. Rollier has never seen cutaneous atrophy follow phototherapy properly applied. The violet and ultra-violet rays used alone have an irritative action on the skin; nevertheless the most acute reactions, even those due to abiotic ultra-violet rays, get well if the irritation is not maintained by other traumatisms. He has never seen cutaneous epithelioma occur in a case of lupus treated only by heliotherapy. In Dr. Rollier's opinion heliotherapy—and he assumes that this applies also to artificial heliotherapy—does not cause any damage when it is applied in a rational manner, but the question of dose plays an important part.

### SLOW HEART.

SIR,—My old friend Dr. Rickard Lloyd's letter (May 2nd, p. 860) brings to memory a very remarkable case I had to deal with many years ago. An elderly man was to be operated on for obstructed inguinal hernia. Sir Rickman Godlee, who was the surgeon, told me that the patient's pulse was abnormally slow, and that under chloroform it would become slower, as it had done when he was operated on for a similar condition some time previously. Sure enough, before operation the pulse was 25 to 28; when fully under it dropped to 12 to 15 a minute. His breathing remained slow but regular all the time, but it was a rather trying experience to count five to six full seconds for each

beat. I went on the old rule, "Watch the breathing and keep the airway open," and all went well. The case was a remarkable one, as the patient had a double hernia with practically all his bowels in his scrotum. The patient recovered, but died some little time after from another trouble.—I am, etc.,

Appledore, Kent, May 2nd.

F. WILLIAM COCK.

#### APPENDICITIS.

SIR,—I was much interested in Mr. Sherren's article on the symptoms of appendicitis, in the *BRITISH MEDICAL JOURNAL* of April 18th (p. 727). I should be grateful if he or some other surgeon or pathologist would solve a mystery that has been puzzling me for years—that is, What is the cause of the suddenness of the pain which usually ushers in appendicitis—what pathological or mechanical change occurs at the moment of onset? Is it obstruction and distension of the appendicular tube? If so, is an appendicitis which is characterized by a more gradual onset of a different type, and likely to take a different course, from one commencing suddenly?

An interpretation of the symptoms in appendicitis by those who have the opportunity would enable us general practitioners to read our cases with a more intelligent interest, and consequently diagnose them more accurately and earlier.—I am, etc.,

Croydon, April 28th.

T. A. BLACE, M.B.

#### INDIVIDUAL MEDICAL DEFENCE.

SIR,—The recurring suggestion that the British Medical Association should undertake individual medical defence has now, apparently, received the qualified support of the Council, and will appear before the Representative Meeting in rather a new form.

What the Representative Body will do will be interesting to watch, as the present suggested policy is diametrically opposed to previous decisions of the Representative Body. I think it is a fact that at Edinburgh in 1898 it was definitely decided that the British Medical Association should not undertake medical defence; and again, at Leicester in 1905, a resolution was carried that it was inadvisable for the Association to undertake medical defence in competition with the existing societies. Other Annual Representative Meetings have also turned down similar suggestions. Apart from this, however, let us examine this suggestion on its merits.

The Medical Defence Union (of which society I know most) has as its General Secretary an ex-Deputy Medical Secretary of the British Medical Association, and on the Council are the present Honorary Librarian, one member of the Council of the British Medical Association, and a past Chairman of the Representative Body. Other members of the Council of the Medical Defence Union are also members of the British Medical Association. Surely the British Medical Association could hardly hope for any committee or governing body, even if entirely nominated by itself, to have more regard for members of the British Medical Association.

Again, the accumulated funds of the existing defence societies form a protection to members that no new society could hope to give for many years to come. It would even be possible that heavy claims in the first year or so might break a society which embraces only some 6,000 to 7,000 members.

Another point. The position of the individual who resigns from one of the existing societies to join the new one would be somewhat precarious. On his resignation he forfeits all protection for any matter occurring prior to his resignation. A new society is not likely to give retrospective protection; it could not possibly afford to do so. Thus there would be an interregnum, during which the individual would be totally unprotected.

I am a keen supporter of the British Medical Association, and have done a good deal of work for it at one time and another; but I should be very sorry to see it embark upon this fresh scheme for many reasons, a few of which I have mentioned above.—I am, etc.,

Birmingham, April 28th.

W. TRACEY LINDALL.

SIR,—In your issue of May 2nd (p. 861) Dr. Manson refers to the early history of the medical defence question, both within and without the British Medical Association.

Thanks to the researches of the Association's Intelligence Officer, I am able to give some of the details for the benefit of those who are interested.

On February 13th, 1886, it is recorded that the following resolution was unanimously passed by the Essex district of the East Anglian Branch:

"That as medical men may at any time become liable to false and groundless charges of a ruinous nature, it is most desirable that a medical defence fund be formed and administered in connexion with the British Medical Association, and that its members should be asked to contribute a small sum annually to this fund, those who do so becoming entitled, if occasion arise, to legal advice and assistance."

It was in the same year (1886) that the Medical Defence Union was formed as the result of a meeting held in May at the Medical Institute at Birmingham.

It would appear, however, that considerable discussion must have taken place within the Association for at least ten years previous to 1886, as Mr. George Brown, speaking to a resolution moved by Dr. Arthur Welsford at the Annual Meeting in London in 1895, stated "that he had wrestled with the Council for twenty years on this subject."—I am, etc.,

S. MORTON MACKENZIE,  
Chairman, Organization Committee,  
British Medical Association.

Dorking, May 2nd.

SIR,—Dr. Manson's reply to my letter on this subject discloses a number of misapprehensions, and I ask leave to make my argument clearer to him than my previous letter appears to have done.

He attributes to me the view that what would have been right in 1880 is wrong in 1925. What I said was that a certain course which would have been expedient in the circumstances of 1880 is not expedient in those of 1925, and I went into details of the changed circumstances.

I urged the overwhelming importance of a large reserve fund to a medical defence society; and pointed out that the Medical Defence Union and the London and Counties Medical Protection Society have such reserves, whereas the new company which it is suggested should be started under the auspices of the British Medical Association will have none. Dr. Manson glazes over this issue, and replies that the existence of these reserves proves how profitable is the work of medical defence, and how probable it is that in time the new company will also possess a reserve. It has taken the Defence Union forty years, and the Protection Society thirty-three years, to accumulate their respective reserves; and both societies in their early years risked bankruptcy in the process. The risk had to be run because it was the only way by which medical and dental practitioners could get individual medical defence. The risk still confronts any new society, and is definitely greater than it was forty years ago. Then why start a company which has to run such a risk when the existing societies have got beyond it? And which society is likely first to be able to reduce subscription rates—that which has a reserve of thousands of pounds, or that which may with luck hope to have an equal amount in forty years' time?

I disagree with Dr. Manson's thesis that a number of societies (necessarily weak ones, of course) are preferable to two strong ones. Personally I hold that one exceedingly powerful society would be even better. He puts forward in mitigation of the argument of the wastefulness of multiple offices, secretaries, and overhead charges in general, that no doubt the British Medical Association would let the new company have cheap office accommodation in the new buildings. Does Dr. Manson not perceive that this merely shifts on to the Association part of the burden in question, and that my argument that these multiple overhead charges come out of the pockets of the medical profession is unanswered?

I hope to see Dr. Manson withdraw unreservedly the paragraph in which he speaks of the relations between the Medical Defence Union and the Yorkshire Insurance Company, because upon reflection he will realize that the words he has used are bound to create a wrong impression and

to mislead. I demur also to his belief that "very little is happening in the defence societies," which is the inference he draws from my statement (not disputed by him) that there is extraordinarily little dissatisfaction among the members of the two defence societies. His inference is not only illogical, it is also incorrect.

One last point. Dr. Manson asks whether the Medical Defence Union would prosecute a member of the Union before the General Medical Council for a grave professional offence. It is *ultra vires* for the Medical Defence Union to do such a thing, and it will be equally *ultra vires* for the new company that Dr. Manson wants to see started to act similarly to a member of that company. This is a question of law; thus the aspirations expressed in his last paragraph are unattainable, because the law prevents their realization.—I am, etc.,

London, S.W., May 3rd.

HENRY ROBINSON.

SIR,—I read Dr. Manson's criticism of Dr. Robinson with much interest till I reached the last paragraph; then I rubbed my eyes. He desires to know if a medical defence society "would prosecute a member before the General Medical Council for advertising, touting, or other grave professional offence." He intimates not. There is a case for the British Medical Association undertaking the responsibility of a defence society, and against. But Dr. Manson's naïve query, I hazard, settles it. The idea of the British Medical Association prosecuting its own members is too entrancing.

Medical ethics, medical amenities, comprise a curious world, in a jealous profession. Sir William Osler plaintively refers to it in his writings, and the best antidote, as he always maintained, is a liberal education. The British Medical Association is constituted on a broad, democratic basis, I take it, for medical politics. The addition of the function could but weaken it.—I am, etc.,

London, N.W., May 3rd.

RICHARD GILLBARD.

#### HARVEY MEMORIAL AT HEMPSTEAD.

SIR,—By this time all members of the Association (and practitioners who are not) have doubtless received the circular from the Harvey Church Tower Memorial Fund Committee, appealing for monetary aid to erect a fabric to be named after the great William Harvey, and to restore to its pristine beauty the interesting old church at Hempstead, Essex, in which he (and many members of the Harvey family) was buried. I intended, in the first instance, to ask a few of my immediate medical colleagues to join with me in making at least some response to the appeal. But on reflection it seemed that a move in the same direction by the Association through the JOURNAL would be more appropriate and infinitely more effective.

The small subscription of half a crown from every British practitioner would, it appears, be sufficient to finance the project. There are two reasons why all should respond—first, because an old fourteenth century church requires restoration, and, again, the great and momentous discovery of a fellow countryman and physician is to be suitably recorded in stone.—I am, etc.,

London, N.W., May 1st.

HOPE GRANT, F.R.C.S., etc.

\* \* A note on the subject of Mr. Hope Grant's letter appears elsewhere, at page 895.

### The Services.

#### OSBORNE CONVALESCENT HOME.

THE KING has approved of the reappointment of the following to the consulting staff of King Edward VII's Convalescent Home at Osborne, Isle of Wight, for officers of H.M. Navy, Army, and Air Force: Sir Cuthbert Wallace, K.C.M.G., C.B., F.R.C.S., Sir Herbert Waterhouse, M.D., F.R.C.S., G. E. Gask, C.M.G., D.S.O., F.R.C.S., Sir W. H. Wilcox, K.C.I.E., C.B., C.M.G., M.B., F.R.C.P., C. H. Miller, C.B.E., M.D., F.R.C.P., H. S. French, C.B.E., M.D., F.R.C.P., H. Morley Fletcher, M.D., F.R.C.P.

#### TERRITORIAL DECORATION.

THE KING has conferred the Territorial Decoration upon the following medical officers: Colonel Frank G. Proudfoot, M.D. Royal Army Medical Corps; Lieut.-Colonels R. M. Vick, O.B.E., Sir Ewen J. Maclean (ret.), Major R. Coffey, E. J. Boome, D. S. Sutherland, A. E. Webb-Johnson, C.B.E., D.S.O.

#### INDIAN MEDICAL SERVICE.

As already announced, the annual dinner of the Indian Medical Service in London will be held at the Trocadero on Wednesday, June 17th. Lieut.-Colonel A. W. Alcock, C.I.E., F.R.S., will be in the chair. Tickets and all particulars may be obtained from the joint honorary secretary, Colonel J. J. Pratt, I.M.S. (ret.), 18, Nevern Mansions, Warwick Road, S.W.5.

### Universities and Colleges.

#### UNIVERSITY OF OXFORD.

At a congregation held on April 30th the degrees of M.A. and D.M. were conferred on H. D. Haldin-Davies.

#### UNIVERSITY OF SHEFFIELD.

Dr. B. Brouwer, professor in the University of Amsterdam, will give a lecture (in English) entitled "The projection of the retina in the brain," on Tuesday, May 19th, at 8.45 p.m., in the Medical Library, the University of Sheffield. All medical practitioners are invited.

#### UNIVERSITY OF DUBLIN.

##### TRINITY COLLEGE.

At the first summer commencements, held on April 28th, the undermentioned degrees were among those conferred:

M.D.—J. C. J. Callanan, R. A. D. Pope.  
Sc.D.—J. W. Bigger, M.D.

#### ROYAL COLLEGE OF PHYSICIANS OF LONDON.

An ordinary comitia of the College was held on April 30th, the chair being occupied by the President, Sir Humphry Rolleston.

##### Fellowship.

The following were elected to the Fellowship:

Robt. C.B.E., M.D. Lond.  
(London), Frederic  
William MacNee,  
M.D. Lond. (London).

##### Membership.

The following candidates, having passed the required examination, were admitted Members:

Frederick M. B. Allen, M.D. Relf., Herbert A. Brookes, M.B. Edin., Morris J. Cohen, M.D. Liverp., Leslie B. Cole, M.B. Camb., Robert H. Cook, M.B. Lond., Macdonald Critchley, M.D. Bristol, John N. Cruickshank, M.D. Glasg., Charles F. Harris, M.B. Lond., Amy Hodgson, M.D. Liverp., William A. Lister, M.R.C.S., L.R.C.P., J. Oxf., David C. Muir, M.B. Lond., Robert D. Power, M.D. Dub., D'Arcy J. Prendergast, M.D. Lond., Chennagiri K. Rau, M.D. Madras, and Ambrose Spong, M.D. Manch.

##### Licence.

Licences to practise physic were granted to the following 138 candidates, who have passed the Final Examination of the Conjoint Board and have complied with the by-laws of the College:

C. S. Anderson, W. A. Barnes, St. C. E. J. Barrett, I. C. P. Beauchamp, J. H. Beagley, Diana J. K. Beck, P. B. T. Becker, Elizabeth E. Benson, C. P. Blacker, W. B. Bomer-Morgan, E. H. Boodrio, D. de C. Boxhill, P. G. Brain, M. K. Braybrooke, R. B. Bray, C. W. Brook, G. M. Brooks, J. F. Butler, L. I. M. Castleden, I. A. D. Ceirios-Cadle, M. Chandra, R. J. K. Chatter, J. E. Church, Hilda A. Cohen, Jean Cooper, Catherine A. Cowan, P. V. Cramer, D. P. Crawford, D. A. L. Crawshaw, Victoria M. Crosse, G. P. Crowden, J. Crowther, J. Cumming, R. N. Curnow, R. R. Dalling, H. E. Daniel, R. K. Dehenham, A. E. De Hazal, J. D. Dillon, W. H. A. Dodd, A. S. M. Douglas, J. L. C. Doyle, G. I. Evans, P. F. Evans, Christabel S. Eyre, C. R. Fielding, F. J. T. Focander, C. A. Francis, D. B. Fraser, H. E. Gamlen, A. W. Gardner, J. H. Gibbens, G. D. Gilbard, A. Gompertz, R. T. Gooden, D. R. Grant, G. S. Hale, C. Howard, Marjorie F. M. Hayward, J. E. Howie, W. Hughes, J. T. Hunter, go, L. E. Jones, L. R. Jones, W. H. M. Kapur, R. St. J. Kemm, G. M. King, J. G. Kingsbury, C. K. Lakshmanan, J. C. C. Langford, Kathleen M. Lankester, G. A. Q. Lennane, H. M. O. Lester, Muriel A. Lester, T. J. Lloyd, A. McMillan, S. P. Meacock, J. G. Milner, V. S. Mitcheon, S. K. Montgomery, A. J. Moody, C. A. Moody, Florence I. R. Moore, W. G. B. Morris, C. A. Mulligan, Marjorie Murrell, V. Ogden, J. B. Oldham, Dorothy M. Payton, A. P. Pearce, C. O. Peters, A. Pierce, E. P. Pratt, B. Press, J. Rafalowsky, S. Randall, Grace D. Rice, H. S. Rich, G. D. Robb, J. E. C. Rouse, A. T. F. Rowley, T. A. Seeking, R. Sellick, G. D. Shields, J. R. Smith, J. S. Spickett, A. A. Spiro, E. F. Stead, G. H. Steele, J. S. Symons, Catherine F. Taylor, G. Taylor, Henrietta Trend, Joan W. Urwick, K. H. Uttley, J. M. van Schalkwyk, Y. S. Wan, E. C. Warner, R. L. Waterfield, M. A. Weisman, W. S. Whimster, R. M. Winder, K. K. Wood, J. Wood, H. M. Woodman, and H. C. Wykerd.

##### Diplomas.

Diplomas in the undermentioned subjects were granted, jointly with the Royal College of Surgeons of England, to the following candidates:

Diploma in Public Health.—J. V. Armstrong, Amarnath Bajaj, Bal Mokand, E. M. Berghem, E. R. W. Gilmore, Andrew M. Hughes, J. A. Kerr, J. H. M. Lloyd, Marian Lones, H. L. Oldershaw, Ethel B. Poole, Gian Singh, L. H. D. Thornton, J. G. Walker, and Moreen Whelton.

*Diploma in Tropical Medicine and Hygiene.*—Bal Mokand, J. N. Banks, A. Blair, J. H. Bowyer, H. H. Brown, E. N. Cook, A. C. Craighead, N. E. Goldsworthy, T. S. Goodwin, P. F. A. Grant, A. N. Hawthorth, L. H. Henderson, S. Khan, R. A. E. Klaher, E. Lumsden, J. R. Maleri, J. S. E. Manloy, A. S. Mohammed, H. J. More, J. W. Scharff, E. B. Struthers, and J. L. Stuart. (All the above were students at the London School of Hygiene and Tropical Medicine.)

Sir Wilnot Herringham, K.C.M.G., M.D., was re-elected as Representative of the College on the Senate of the University of London.

Dr. William Gordon was nominated to represent the College at the Congress on Thalasso-Therapeutics at Arcachon, France. Dr. Raymond Crawford was elected Registrar of the College. A report from the Committee of Management was received and adopted, also the quarterly report of the examiners for the licence on the examinations held in January last. The report of the Committee on Regulations for the Membership Examination was received and was in part referred back for further consideration. Books and other donations to the library presented during the last quarter were received.

The President then dissolved the comitia.

#### SOCIETY OF APOTHECARIES OF LONDON.

The following candidates have passed in the subjects indicated:

*SURGERY.*—T. A. Lazaro, I. H. Mackay, K. E. R. Robertson, F. Smith (Section II), P. W. Tobin.  
*MEDICINE.*—E. H. Boodrie, F. Carroll, T. G. L. Davies, C. M. Moody, A. B. Osbourne, J. Wilson.  
*FORENSIC MEDICINE.*—F. Carroll, P. H. Knowles, C. H. Mason, A. B. Osbourne, O. W. Percival.  
*MIDWIFERY.*—R. V. Cookes, B. Horwitz, T. McD. Kellough, P. H. Knowles, C. S. Netscher, W. I. Pierce, S. H. G. Pimm, G. E. Rowan, B. L. Steele, R. F. Stubbs, P. W. Tobin, D. Winstanley.

The diploma of the Society has been granted to Messrs. E. H. Boodrie, T. McD. Kellough, C. M. Moody, B. L. Steele, R. F. Stubbs, J. Wilson.

### Obituary.

DR. ARTHUR BANCES PROWSE died at Clifton on April 26th in his 70th year. He was the son of Dr. William Prowse and grandson of Dr. James Prowse, who practised in St. James Barton. He received his early education at Amersham College, and subsequently became a student at the Liverpool School of Medicine, and St. Mary's Hospital, London. He took the diplomas of M.R.C.S.Eng. in 1877 and F.R.C.S. in 1882, graduated M.B.Lond. with honours in medicine, forensic medicine, and obstetric medicine in 1878, and proceeded M.D. in 1881. He was appointed assistant surgeon to the Bristol Royal Infirmary in 1883, and in 1888 succeeded Dr. W. H. Spencer as physician, a post which he held until 1919, when he retired and was appointed honorary consulting physician. Dr. Prowse served for seventeen years as a lecturer on materia medica, pharmacology, and therapeutics in the Bristol Medical School, and was honorary financial secretary on the occasion of the Annual Meeting of the British Medical Association at Bristol in 1894. He was appointed to the command of the 2nd Southern General Hospital in 1919, with the rank of lieutenant-colonel R.A.M.C.(T.).

DR. ARTHUR STORRS, who died at Capri on February 6th, received his medical education in Edinburgh and McGill Universities. He graduated M.D.McGill in 1876, and received the Edinburgh diplomas L.R.C.P., L.M. 1879, and the M.R.C.P. in 1882. A colleague of very long standing (A. D. W.) writes: We were both born and brought up in the Annapolis Valley, Nova Scotia, in sight of the Minas Basin of the Bay of Fundy, his father being rector of a parish near the famous Arcadian village of Longfellow's *Evangeline*. He was educated at Horton Academy and King's College. We studied medicine together at McGill University, and both came home and settled in practice on this side of the Atlantic—he in England and I in Scotland. From Barnsley he went to practise at Mexborough, and afterwards in Southport; three years ago he retired to Bovey Tracey, Devon. His work as a practitioner of medicine would have rejoiced the heart of the late Sir James Mackenzie; he was so precise and methodical, so anxious and exact in diagnosis, so careful of every interest of his patient, and so skilful in treatment. He was a connoisseur in old china, and croquet was his favourite recreation. He only allowed himself a brief summer holiday, often choosing to spend it among the Scottish

Highlands. His first wife, for many years an invalid, died not long after he retired. In October last he set out, after his marriage with Mrs. Romilly of Southport, for warmer climes, hoping to accomplish a long desired visit to Palestine. At Cannes he contracted a slight chill, which at Capri developed into bronchopneumonia, of which he died. The remains were brought to England and buried at Bovey Tracey. He leaves his wife and many friends to mourn his loss.

DR. HERBERT LIVINGSTON EVANS of Goring-on-Thames, who died on April 9th after a short illness, aged 65, was educated at Clifton College, Edinburgh University, and Guy's Hospital Medical School. He graduated M.B., C.M.Ed. in 1887. After serving as clinical assistant at the Bristol Eye Hospital he settled in practice at Goring some thirty-six years ago. He was assistant medical inspector of schools, medical officer and public vaccinator for the No. 2 District of the Bradfield Union, and medical officer to the Post Office. In his earlier days Dr. Evans was a fine athlete, and during three seasons played for Scotland in international Rugby football matches. He was a member of the Reading Division of the British Medical Association.

DR. HENRY TRENTHAM MAW, who died at Westcott, near Dorking, on April 23rd, aged 58, was educated at Repton and Christ's College, Cambridge, and studied medicine at St. Bartholomew's Hospital. He took the diplomas of L.R.C.P. and M.R.C.S. in 1892, graduated M.B., B.Ch.Cantab. in the following year, and proceeded M.D. in 1896. He served as house-surgeon at the Leeds General Infirmary and the Hospital for Sick Children, Great Ormond Street, and resident medical officer at the Royal Hospital for Diseases of the Chest, City Road. He had been a partner in the well known firm of Messrs. S. Maw, Son and Sons, Ltd., since 1901, and became chairman of the board of directors on the death of his brother, Mr. C. T. Maw, in 1918.

DR. ALEXANDER CHRISTY WILSON, who died at Doncaster on April 27th in his 80th year, was the son of Mr. Walter Wilson of Hawick. He received his medical education at the University of Edinburgh and in Paris, took the diploma of L.R.C.S. Edin. in 1866, graduated M.B., C.M.Edin. in 1867, and proceeded M.D. in 1870. After holding resident posts at the Edinburgh Royal Infirmary, he settled in practice at Doncaster some fifty-five years ago. For over forty years he was an honorary surgeon to the Doncaster Royal Infirmary, and on his retirement was appointed consulting surgeon. He was a member of the Royal Medical Society of Edinburgh, and had served as president of the Leeds and West Riding Medico-Chirurgical Society and of the Yorkshire Branch of the British Medical Association. In 1923 he and his wife celebrated their golden wedding. He is survived by his widow and two sons, both of whom are members of the medical profession.

DR. ARTHUR HEFFTER, director of the Institute of Pharmacology in Berlin, and author of various works on pharmacology and toxicology, has died at the age of 65.

DR. SIDNEY ALRUTZ, director of the Institute of Experimental Psychology at Upsala, and well known for his investigations on the sensibility of the skin, has recently died.

DR. GIUSEPPE RUGGI, formerly senior surgeon to the Ospedale Maggiore, Milan, and one of the pioneers of Listerism in Italy, and Dr. GAETANO GAGLIO, professor of pharmacology in the University of Rome, and author of a well known treatise on pharmacology, have recently died.

M. ALEXANDRE MALOINE, the well known Paris medical publisher and bookseller, has died at the age of 76.

## Medical News.

DURING his visit to Sierra Leone the Prince of Wales made an inspection of the Sir Alfred Lewis Jones Tropical Research Laboratory. This branch of the Liverpool School of Tropical Medicine was built after the war out of funds bequeathed by the founder of the Liverpool School of Tropical Medicine. Sir Alfred Jones, aware of the handicap to commercial development caused by the diseases of tropical West Africa, wished that research institutes for the study of such diseases should be established in places where these diseases are rampant; Sierra Leone was the first locality chosen by him. His Royal Highness with his staff visited the laboratory on April 7th and was met by the Director, Professor B. Blacklock, with Mrs. Blacklock, Dr. Gordon, assistant director, and Dr. Macdonald, research assistant. A series of exhibits was shown, illustrating the life-histories of insects and parasites.

THE appeal on behalf of the British Institute of Radiology, to which we referred on November 8th, 1924 (p. 872), has resulted in a sum of £1,680 having received up to April 10th, of which £238 was definitely allocated to the Reid Memorial Fund. This sum has been mainly contributed by radiologists, and, in order that the total amount required (£6,000) may be obtained, it will be necessary for the general public, as well as members of the medical profession other than radiologists, to co-operate.

PROFESSOR ELLIOT SMITH will deliver a lecture, with lantern illustrations, on "The Taungs skull—missing links" at University College, London, on Friday, May 22nd, at 5.30 p.m. The proceeds from the sale of tickets will be devoted to the St. Christopher's Working Boys' Club, which is largely maintained and organized by the students and staff of University College. Particulars can be obtained by sending a stamped addressed envelope to Miss Hushands, University College, London, Gower Street, W.C.1.

THE annual oration before the Medical Society of London will be delivered by Sir William Hale-White, K.B.E., M.D., on Monday evening next, May 11th, at 9 o'clock. The subject is "The medical career of John Keats." The president, Dr. Eustace M. Callender, C.B.E., will receive Fellows and guests at 8.30 p.m., and the oration will be followed by a conversation.

THE next dinner and smoking concert of the Cambridge Graduates' Medical Club will be held at the Langham Hotel, Portland Place, W.1, on Wednesday, May 27th, at 7 for 7.30 p.m. The president of the club, Sir Humphry Rolleston, Bt., K.C.B., P.R.C.P., Regius Professor of Physic in the University of Cambridge, will take the chair. The price of the dinner, exclusive of wine, is 10s. 6d. The honorary secretary is Mr. W. H. C. Romanis, F.R.C.S., 31, Harley Street, W.1.

THE dinner of the Queen's University Club, London, will be held at the Connaught Rooms, Great Queen Street, on Thursday, May 21st. Among the guests will be Lord Carson, Mr. Winston Churchill, and Sir John Ross, formerly Lord Chancellor of Ireland.

THE annual dinner of the Harveian Society of London will be held at the Connaught Rooms, Great Queen Street, on Thursday, June 11th, at 7.30 p.m.

THE next quarterly meeting of the Medico-Psychological Association of Great Britain and Ireland will be held on Thursday, May 21st, at the house of the Medical Society of London, at 2.30 p.m., when Dr. J. Shaw Bolton will deliver the Maudsley Lecture, entitled "Mind and Brain."

TWO Chadwick public lectures (illustrated with epidiascope and lantern slides) will be given in London this month by Dr. Emile Brumpt, professor of the Faculty of Medicine in the University of Paris. The first, on how to conduct an antimalarial campaign, will be delivered in the Barnes Hall, Royal Society of Medicine, 1, Wimpole Street, W., on Monday, May 25th, at 5.15 p.m., with Sir William J. Collins in the chair. The second, on the prophylaxis of sleeping sickness, will be delivered in the lecture room, Royal Society of Arts, John Street, Adelphi, W.C., on Friday, May 29th, at 5.15 p.m., with Sir James Crichton-Browne in the chair. Immediately preceding Professor Brumpt's first lecture the Chadwick Gold Medal and Royal Air Force Prize of £100 will be presented to Wing-Commander Harold E. Whittingham, who during the past five years has specially assisted in promoting the health of the men of the Royal Air Force. This award is made in accordance with the scheme of the Chadwick Trust, upon the nomination of the Director of Medical Services, R.A.F.

THE London (Royal Free Hospital) School of Medicine for Women has purchased 6½ acres of freehold land at Sudbury for a sports ground for the students of the school.

THE Fellowship of Medicine announces that on May 12th, at 5.30 p.m., Mr. J. P. Lockhart-Mummery will lecture at No. 1, Wimpole Street, on the diagnosis and treatment of internal piles. From May 18th to 29th the London Temperance Hospital will hold a course for general practitioners; a clinical demonstration will be given at 4.30 p.m., followed by a short lecture at 5.30. A course in psycho-logical medicine at the Maudsley Hospital began on May 4th. The Central London Throat, Nose, and Ear Hospital will hold a special course from May 11th to 30th, consisting of clinical demonstrations with out-patient clinics and ward rounds; an operative surgery class will also be arranged. From May 18th to the end of the month there will be a special course at the Infants Hospital, consisting of lectures, out-patients' clinics, "round table" consultations, and visits to four different centres outside the hospital. There will also be a two weeks' course in dermatology from May 18th at the Hospital for Diseases of the Skin, Blackfriars; instruction will be given in the out-patients' department from 2.30 p.m., with a special demonstration on selected cases on May 19th, together with venereal clinics twice weekly. There will be courses in June at the Victoria Park Hospital for Diseases of the Heart and Lungs, the Chelsea Hospital for Women, the London School of Hygiene and Tropical Medicine, the London Lock Hospital, and an intensive course at the London Temperance Hospital and associated hospitals. Full particulars of these courses may be obtained from the Secretary of the Fellowship of Medicine at No. 1, Wimpole Street, W.1.

THE party arranged by the Inter-State Post-Graduate Assembly of America, which is to visit this country in June under the leadership of Dr. Charles Mayo, will spend the first week in London, where it will visit a large number of hospitals and medical institutions. The Duke of York will attend the opening ceremony on June 2nd. On June 2nd there will be a garden party at the London Hospital, when Dr. Charles Mayo will present the prizes to students. On June 3rd there will be an evening reception at the Royal Society of Medicine, and on June 4th a garden party at St. Bartholomew's Hospital. On June 5th there will be an afternoon reception at the Royal College of Surgeons, and on the evening of the same day Dr. Mayo and the members of the advisory committee of the Inter-State Post-Graduate Assembly of America will give a dinner at the Guildhall. On the afternoon of June 6th a garden party will be given at Crewe House by H.E. the American Ambassador and Mrs. Houghton, and in the evening of that day Dr. Mayo will be entertained to dinner by the Section of Surgery of the Royal Society of Medicine. The party will afterwards visit Manchester, Liverpool, Leeds, Dublin, Belfast, Glasgow, Edinburgh, and Newcastle, and will then proceed to Paris.

THE Board of Education has issued a revised form of the report in connexion with the medical examination of mentally deficient children (Form 306 M, or Schedule F, of the Board's Revised Model Arrangements). Local authorities will be permitted to use alternative forms, provided that such forms are so constructed as to include the same information as in the new form. The Board has also issued a revised form of report or use by head teachers in the case of children whose education is retarded (Form 41 D), certain recognized tests of scholastic attainments, reprinted from Burt's *Handbook of Tests for Use in Schools*, being incorporated in it. Certificate forms (311 M and 312 M) have now been provided for the purpose of reporting to the local authority cases in which a child is an idiot, imbecile, or moral imbecile.

SIR GILBERT WHEATON FOX of Liverpool bequeathed £2,000 to the Liverpool Royal Infirmary, £1,000 each to the Royal Southern Hospital, the David Lewis Northern Hospital, the Stanley Hospital, and the Birkenhead Borough Hospital. Miss Mary Russell of Manchester, who left estate of the gross value of £50,618, with net personalty £60,525, directed that after the fulfilment of a number of personal legacies the residue of the property is to be divided between the Christie Hospital Cancer Pavilion and Home, St. Mary's Hospitals, Manchester, the Manchester Royal Infirmary, the Manchester Eye Hospital, the Salford Royal Hospital, and the Royal National Lifeboat Institution. Sir William C. Gray of Bedale, Yorks, who died in November last, bequeathed £5,000 to the Hospitals Trust of the Hartlepoons and £2,000 to the Victoria Homes, West Hartlepool.

THE Cambridge University Press announces, for early publication Volume XIX of the Royal Society's *Catalogue of Scientific Papers*, covering the letters T-Z during the years 1884-1900.

THE fifth Northern Surgical Congress will be held at Copenhagen, under the presidency of Professor Rorsing, from June 25th to 27th, when the following subjects will be discussed: treatment of acute osteomyelitis and its sequelae; non-tuberculous disease of the adnexa; tuberculosis of the kidneys and urinary tract. The general secretary is Professor P. Bull, Incognitogade 26, Oslo, Norway.

It is proposed to erect a new nurses' home in connexion with the Elizabeth Garrett Anderson Hospital at a cost of £15,000 as a memorial to the ninety-seven members of the Overseas Nursing Services who died in the war. A reception will be held by the Dowager Marchioness of Dufferin and Ava, chairman of the Memorial Fund, in the Conference Hall, Wembley, on May 23rd, at 3.30 p.m. Subscriptions should be sent to her at the Elizabeth Garrett Anderson Hospital, 144, Euston Road, N.W.1, and further information can be obtained from the Secretary, Overseas Memorial Committee, at the same address.

A SYMPATHETIC obituary notice of Sir James Mackenzie, with a portrait, appears in *Il Policlinico* of April 20th.

A COURSE of instruction in diagnosis of diseases of the heart will be held at Naubeim from May 25th to 30th. Further information can be obtained from Dr. Gabriel, Zander Institut, Naubeim.

A CONGRESS of physiotherapy will be held at Leningrad, under the presidency of Professor A. S. Brustein, from May 23rd to 27th, when the following papers will be read: helleotherapy, by Professor Brustein; ionotherapy, by Professor S. B. Vermel; physiotherapy of arthropathies, by Professor A. L. Polianov; physiotherapy of endocrine disturbances, by Professor G. M. Czernizky.

THE volume of the report on the Census of England and Wales (1921), dealing with dependency, orphanhood, and fertility, was issued on May 7th. It contains 252 pages of tables, 230 of them relating to dependency, including particulars of the numbers and sizes of families of children under 16 years. Its price is £1 10s.

THE Royal Society will give its first conversazione for this year on the evening of Wednesday next, May 13th.

THE medical faculty of Copenhagen has offered a prize of 5,000 kronen for the best critical study of the modern surgery of the sympathetic nervous system.

## Letters, Notes, and Answers.

ALL communications in regard to editorial business should be addressed to **THE EDITOR, British Medical Journal, 429, Strand, W.C.2.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the **BRITISH MEDICAL JOURNAL** alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Matter intended for the current issue should be posted so as to arrive by the first post on Monday, though in special circumstances urgent communications can usually be received on Tuesday morning.

Authors desiring REPRINTS of their articles published in the **BRITISH MEDICAL JOURNAL** must communicate with the Financial Secretary and Business Manager, 429, Strand, W.C.2, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the **JOURNAL**, should be addressed to the Financial Secretary and Business Manager, 429, Strand, W.C.2. Attention to this request will avoid delay.

The TELEPHONE NUMBER of the **BRITISH MEDICAL ASSOCIATION** and **BRITISH MEDICAL JOURNAL** is **GERARD 2630** (Internal Exchange).

The TELEGRAPHIC ADDRESSES are—

EDITOR of the **BRITISH MEDICAL JOURNAL**, *Antology Westrand, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westrand, London.*

MEDICAL SECRETARY, *Mediscera Westrand, London.*

The address of the Irish Office of the **BRITISH MEDICAL ASSOCIATION** is 16, South Frederick Street, Dublin (telegrams: *Daedalus, Dublin*; telephone: 4737 Dublin), and of the Scottish Office, 6, Rutland Square, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 4361 Central).

## QUERIES AND ANSWERS.

"X" writes: I have a patient who has the greatest dread of thunderstorms. Can any reader suggest a plan for giving relief?

"BORNEO" writes: I have a patient who is not a true "bleeder," but who, on having three teeth extracted, nearly bled to death. That is fifteen years ago. His teeth are now in a very bad state and should all be extracted. What is one to do to prevent recurrence of the bleeding?

## THE TREATMENT OF FIBROSITIS.

Dr. R. CHALMERS (Darlington) asks for information as to the dose of trisodic potassium phosphate recommended by Dr. Ellis during the discussion on the nature, prevention, and treatment of fibrositis, reported in our columns on March 14th (p. 509).

The dose is not given in any book of reference to which we have access, but Dr. Ellis informs us that it should be 2 grains and upwards, according to result. It may disagree and produce general discomfort. It is contraindicated in "alkaline thin gastro-neurasthenic cases." Dr. Ellis adds that the drug should be given carefully; he has gone as high as 10 grains three times daily, but very rarely.

## RELAPSE IN MEASLES.

"G. P." asks: Is there such a thing as a relapse in measles? I can find no reference in the textbooks. Three sisters had typical measles recently; seventeen days later the eldest girl again came out in a typical measles rash, with slight elevation of temperature, injected eyes, and cough. Can this be a true relapse, and must the quarantine period be again extended?

"\*." We find the following references, but they leave the final question unanswered:—Albutt and Rolleston's *System of Medicine*: "It has sometimes been asserted that relapse is of common occurrence in measles, but it seems clear that a true relapse is a very rare event. Some of the cases noted as examples of relapse are really instances of irregular development of the rash; others rest, apparently, upon an error of diagnosis—the first or the second eruption being in reality that of German measles." Osler and McCac's *Principles and Practice of Medicine* (ninth edition): "Relapse is occasionally seen, the symptoms recurring at intervals from ten to forty days; but it is not always easy to say whether there may not have been new infection from without."

## LETTERS, NOTES, ETC.

### EASY WRITING AND HARD READING.

WE are indebted to Dr. C. O. Hawthorne for the following postscript to the note under this heading (April 25th, p. 812), in which he quoted from Moore's *Life of Sheridan*, where it is stated to be quoted from *Clío's Protest*:

I think I have run the couplet to earth. In the form I sent it to you it appears, as stated, in Moore's *Life of Sheridan*, but the page is not 155 but 55. Further, the couplet is quoted alone—I mean without its context. *Clío's Protest* is a topical or personal set of verses apparently intended to scarily a certain "poetaster," and it includes references to a number of persons indicated by initials or by an initial and dashes. Probably no one could now interpret the references, and I take it that this limited interest of the *Protest* explains the exclusion of the lines from volumes offered as *The Works of Sheridan*. They appear, however, together with other odd verses, in two different volumes which I have seen at the British Museum. But there is a disappointment. The full-blooded vigour of "d—d hard reading," as you quoted it, was somewhat reduced in the lines of the *Life*: it became "curst hard reading." A still milder tone marks the original (Thomas Moore did not quote it correctly): it runs "vile hard reading." I have a suspicion that somewhere in Macaulay the "d—d hard reading" may be found, but I cannot turn up the reference. I now send the lines and the immediate context, and plainly they bear out the interpretation you have placed on them:

"If in my strictures I've been free  
—You know the Muse's liberty.  
However I'll make all matters equal  
By wholesome counsel in the sequel.  
And first leave *Panegyric* away;  
"That way," "that way,"  
"your breeding."  
"reading."

From *Clío's Protest*, or the Picture Framed.

### TO RELIEVE PAIN IN BURNS AND SCALDS.

Dr. W. F. MOORE (Kingsbury, Tamworth) writes to recommend as a simple and effective application for pain in burns and scalds equal parts of linseed oil and lime water, with the addition of half an ounce of tincture of opium to each eight ounces. This, he says, stops the pain quickly and is excellent treatment during the painful stage in very severe and very extensive burns. Later he applies an antiseptic, such as boric acid ointment.

## ERRATUM.

In the report of the discussion on puerperal sepsis at the Congress of Obstetrics and Gynaecology, published on May 2nd (p. 831), Dr. F. J. McCann is reported to have expressed the opinion that "puerperal general infection" would be a better term than "puerperal sepsis." The word "general" was a misprint for "genital." He thought it desirable to retain the word "infection" because it brought home the fact that puerperal infection was comparable with wound infection in general surgery.

## VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 35, 36, 37, 40, and 41 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 38 and 39.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 199.

# Lady Jones Lecture ON CRIPPLING DUE TO FRACTURES: ITS PREVENTION AND REMEDY.

DELIVERED BEFORE THE UNIVERSITY OF LIVERPOOL,  
MAY 12TH, 1925,  
BY

SIR ROBERT JONES, K.B.E., C.B., M.Ch., F.R.C.S.

There are personal associations so intimately woven into the texture of this occasion that it is my duty in gratitude and in remembrance to recall them. This first triennial lecture was inaugurated by Mr. John Rankin in memory of my wife. To him I offer my deep gratitude for a thought that you will understand cannot be expressed in conventional terms, but must be accepted in terms that are nearer to silence. Secondly, I have to thank the Council of the University for the privilege—a source of pride as well as gratitude—which they accord me by once again offering me their honoured hospitality in this place.

I have chosen for this lecture a subject which has attracted my attention for many years. It deals with a neglected branch of surgery, and offers suggestions as to the remedy. While dramatic progress has been made in our art as it affects the brain, chest, and abdomen, there has been a deplorable inertia in the surgery of fractures. This is evident when we read the older writers from Hippocrates to Astley Cooper, Percival Pott, and R. W. Smith. The cause is not far to seek. The surgeon of olden days had far fewer problems to solve than are presented to the surgeon of to-day, who is constantly annexing territory previously the province of the physician. The older surgeon consequently had more time to study the deplorable condition of the results of treatment of fractures in this country, and although many of us looked upon some of his operative procedures as drastic his attitude encouraged the spirit of introspection. This is exactly what was, and what is still, needed. I have written so often upon the relative values of open and closed treatment of fractures that I shall not dwell upon this aspect of the matter now. I willingly admit, however, that operative procedure is more than justified if a surgeon cannot obviate malunion and functional defect by non-operative mechanical means. Our position to-day, however, is tragic, for the majority of fractures treated by conservative, or non-operative, methods are badly handled, with resultant disability, and expert operative aid, if desired, is not always at hand. This is the reason I have ventured upon a critical survey of the causes which continue to produce thousands of crippled every year. There is no need to apologize for the choice of subject, whatever may be thought of the way in which it is presented.\*

## LESSONS OF THE WAR.

The treatment of fractures is at present a blot upon our surgical escutcheon. The great war afforded the most convincing proof of the mishandling of complicated, and even of simple, fractures. In the early period these cases arrived home with appalling deformities. Excessive shortening and malunion were the rule. It would, however, be unfair to blame surgeons for this. Men with no experience in this branch of work did the best they could, while men who understood how to treat fractures found the conditions such that it was impossible to obtain satisfactory results. They deplored the fact that the splints supplied were not those to which they were accustomed; that immediate evacuation was inevitable; and that continuity of treatment was impossible. Fractures of the femur serve as a notable

\* Readers are referred to the presidential address of Mr. Muirhead Little on "Specialism and General Surgery," delivered to the British Orthopaedic Association in 1918, and reported in the *Journal of Orthopaedic Surgery*, February, 1919. (A short abstract was published in the *British Medical Journal* for November 30th, 1918, p. 601.)

example. The splint with which we are all so familiar, invented by H. O. Thomas, was barely known, and yet it was the type of splint which ultimately saved the situation. In 1916 the mortality from these fractures amounted to 80 per cent., a large proportion of the deaths occurring on their way to or at the casualty clearing stations. Later, when the Thomas splint was applied almost exclusively, and as near to the firing line as possible, we have it on the authority of Sir Henry Gray that the mortality in 1918 was reduced to 20 per cent. This is an astounding and inspiring fact, and led Colonel Crile, of the United States Army, to say that the Thomas splint did more to prevent death from shock than any other single measure.

The next great advance in the treatment of fractures at the front occurred when we were able to secure the segregation of cases. The country owes a great debt of gratitude to Major Maurice Sinclair for his most excellent work at Boulogne. After our earlier experience it was a delight to meet with his cases. His femurs came over with problems of segregation and of team work had been overcome with very admirable results. In England, however, we were not in a position to segregate these fractures when they arrived. They were distributed to places which were most convenient as regards transport, but they were often denied efficient treatment. Splints were removed too soon, thus sadly interfering with the good work abroad as often changed unnecessarily, and the want of efficient after-care and continuity of treatment. After a time permission was granted that all fractures of the femur should be segregated in our special military centres at home or their arrival from the front, and Colonels Watkin Williams and Pearson, and others, who had done good work in fracture hospitals abroad, were brought home to take charge of them. The results were astonishingly good. In 300 cases treated at one time at the special surgical centre at Edmonton the average shortening was about half an inch. In Liverpool, where 97 cases were at one time at Alder Hey and Knotty Ash, the measurements were similar. At Liverpool the Thomas splint was used in the way to which we are accustomed. At Edmonton the protected ice-tong calliper was employed by Pearson. In all these hospitals gunshot fractures were of the worst type, and the results proved the value of expert supervision, segregation, and team work.

The difference between such results and the average pre-war treatment may be emphasized by the statement of a surgeon to a large teaching hospital, who said of the femur, "I am satisfied if the shortening is not more than from one to two inches." Thomas, over thirty years ago, was unhappy if he had more than half an inch of shortening, and as a boy I have often helped him to put up a fractured femur in his rooms without an anaesthetic, and have immediately afterwards accompanied the patient home in a four-wheeled cab. This experience would more than establish the safety of immediate transport on the field of battle. Let me emphasize again that the success in the treatment of fractures during the later phases of the war was due to expert supervision, simplicity of apparatus, team work, segregation, and appropriate after-care. These are the lessons the war taught us. Are we going to apply them, and improve upon them, or are we to revert to the old bad way? Upon an answer to this question much depends, both in respect to the reputation of our teaching hospitals, and to that of our profession as a whole. It will be admitted that our brethren all over the country, both in the treatment of a fracture entails because of results with which they are only too familiar. This is due to faults of teaching, and the responsibility does not rest with the general practitioner, but with the surgeons who were his teachers. Let us, therefore, first of all deal with our big teaching hospitals.

## METHODS BY WHICH FRACTURES ARE BEING DEALT WITH AT THE "BIG TEACHING HOSPITALS."

I lay stress on the phrase "big teaching hospitals" because their responsibility in teaching generations of medical practitioners is the gravest. They have the means

at their command, both as regards personnel and equipment. What they need is a more modern vision as to the needs of the student. In criticizing our teaching hospitals I may fall into the error of grouping them in such a way as to suggest that their methods are all quite alike. They may and do differ, but not sufficiently to make any of them adequate.

It will, I think, be generally agreed that the teaching of the proper treatment of fractures can only be effective when based on experience, not of mechanical detail alone, but also of the principles which relate to deformity. Every fracture should be looked upon as a potential deformity. Some of these deformities develop in very insidious ways. They may be traced to omissions or commissions, or both. They may arise during treatment, or when treatment is discarded. The least obvious frequently prove the most disabling. Function is impaired, not because of the presence of an ugly lump—often quite harmless—but if strain is cast upon joints above or below the fracture trouble begins. The external contour of a forearm may appear normal even when it hides a cross union. The surgeon called upon to teach should possess the experience enabling him to visualize all such difficulties and dangers, which are sure to encompass the practitioner in after-years. This necessity, however, is not recognized. It is the custom in big teaching hospitals that ambulatory fractures—that is, those among out-patients—are treated by junior officers. These officers are usually not supervised, and the department is not connected with any in-patient service. Results are not inspected by any higher authority. There is no probability that this officer has the knowledge necessary to teach, and it rests with him whether a case should be sent, usually for operation, to the wards. He is not appointed to the post long enough to acquire a sound working knowledge. He starts as the raw material, and rarely graduates as the finished product. To an especial degree what experience he acquires is largely due to mistakes which need never have occurred. This officer remains at his post, which is a subsidiary one, until he is happy enough to be removed to one which he considers more congenial and important. He has no definite period assigned to him with the object of making him useful to the department, but he leaves it when another junior takes his place, who probably repeats all his mistakes. In this way we have a constantly changing personnel, who are neither able to reflect credit on the hospital nor do bare justice to their responsibilities. This system is hopelessly wrong and does not admit of argument, much less of defence.

When we come to deal with recumbent or in-patient fractures we are scarcely, if at all, better off, for they are generally left to the care of the house-surgeon. The honorary surgeon may cast an eye upon them from time to time, but as a rule he resents the occupation of beds by patients in whose infirmity he has little or no interest. Indeed, the house-surgeon is in an awkward dilemma, for he is expected to treat a fracture adequately and expeditiously, while at the same time he is unpopular because he blocks a bed. He has only one thing to do, and as a rule he does it. The fracture is put up in plaster-of-Paris and sent out at the first opportunity. A more unscientific and certainly less satisfactory method it is not easy to conceive. The reduction of a difficult fracture is not the work of a moment, but often of days. There is a finality about placing a fracture in a plaster case which does not admit of compromise, for it assumes the reduction to be immediate, complete, and ended. Readjustment of the bone ends cannot be made. An experienced surgeon knows this, and yet it is a commonplace that fractures of the shaft of the femur are frequently taken into our hospitals to be almost immediately evacuated in plaster. Even more pathetic is the fate of a patient with a fractured neck of the femur, one of the gravest of accidents. Such a case is rarely admitted into the wards of a teaching hospital, but is sent directly to a Poor Law infirmary. I have not an unkind word to say of this type of institution—many of them are most admirably and efficiently conducted. There are some of them, however, quite unfitted for the modern treatment of fractures, and our teaching hospitals should appreciate this fact.

The surgeons, with rare exceptions, neglect to teach because few of them are sufficiently interested or sufficiently informed to do so. They do not emphasize the essential points. Their teaching is perfunctory, not intensive. They pay homage to a duty, but there is no true allegiance. Should the fracture be a spontaneous one, due to a malignant tumour, its rarity arouses every spark of enthusiasm, and opens a fine field for prolonged contemplation. But the common, everyday fracture, the treatment of which may make or mar a student after his graduation, is neglected. Is it a wonder that so many of our large teaching hospitals suffer in reputation? But let us leave this aspect of the matter for a moment and consider the general question from two aspects—the effect on the patient and on the medical student.

#### (a) *The Effect on the Patient.*

The object of treatment is the restoration of function with the least risk to the patient, and the least anxiety to the surgeon. The large proportion of fractures occur in healthy young adults. To them, and to their families, it is of paramount importance that they leave hospital with function restored. Again, it is important that the period of convalescence should be as short as modern methods can ensure. To a surgeon who takes pride in his work the full recovery from a bad fracture should be a thrilling achievement, while malunion, stiffened joints, and wage-earning disabilities should, as correspondingly, fill him with remorse. To the patient it is inconceivable that a hospital with a world-wide reputation should give him anything but the very best, and I think we as a profession feel the same.

#### (b) *The Effect on the Medical Student.*

The effect on the medical student is deplorable. He is brought up in an atmosphere where the teaching of the treatment of fractures is placed in a subsidiary position. It is only after he has qualified that he realizes how little he knows of the subject, and how often by the grim irony of fate he is reminded of it. It is the one department of medicine in which mistakes cannot be hidden, and which the public never forgive. The haunting limp and the well-thumbed radiograph are a constant menace to a surgeon's future, and I have known more than one instance where a young practitioner—the victim to such a fate—has had to strike his camp and travel further afield.

#### COMMON MISTAKES.

Now, what are the common mistakes which we find as the result of imperfect knowledge and deficient tuition? These mistakes are rife both in cases treated within and without our hospitals. I have only time to state a few of them, and they will represent average defects of treatment met with every day in our consulting rooms. To take a common example, it must be recognized that although an end-to-end apposition of a fracture is desirable, it is not essential to perfect function. Indeed, the ill effects following fractures are often due to injury to the soft parts, as may be instanced by ischaemic palsy and injuries to nerves. An end-to-end apposition with imperfect deflection of body weight is infinitely more serious than a slight overlapping, where body weight falls in correct line. The smooth working of a limb depends on preserving the true axis of movement of a joint, so that the stresses of muscular action may act across the joint in normal lines. Otherwise abnormal stress will produce abnormal strain, for we are dealing with living bone in accordance with Wolff's law, which is the physiological equivalent of that universal law that strain is proportional to stress. In dealing with fractures of the shafts of long bones the first consideration, therefore, is to secure a true anatomical alignment of the bone, so that the axis of movement of the joints at the two ends of the bone may retain their correct relative positions. Many crippling deformities are due to a want of recognition of this fact.

Again, let us instance the femur. It is a common experience to find elderly persons, whom the hospitals were unable to treat, handicapped by the extreme disabilities

which follow fracture of the neck of the femur. The limb is shortened, adducted, and rotated outwards, and yet quite a large proportion of such cases simply but properly treated would have resumed their useful citizenship. Abduction and inward rotation under extension would have secured in the limb a range of movement which would have more evenly distributed the pressure of the head in the acetabulum, while later a weight-bearing splint would have prevented the shortening. I have met students who have never seen such a case treated, but in after-life they have never seen it to meet with an old case of fracture of the upper third hobbling with a shortened and adducted limb, his body weight so deflected as to strain both hip and knee. By a simple manipulation and fixation this catastrophe could have been averted. Or it may be a fracture of the middle of the femur with lateral or antero-posterior angulation, with which any practitioner could have dealt if his tuition had been effective. The lessons of the war should have impressed everyone with the knowledge that a femur in good alignment while recumbent would almost surely become crooked if walked upon without weight-bearing protection. Or take that most common and distressing deformity following a fracture of the lower third of the femur due to sagging at the seat of fracture, and resulting in a genu recurvatum. A piece of bandage used as a sling under the seat of fracture should easily prevent such a deformity.

Such deplorable results are frequently found. Every excuse but the right one is offered. A common one is muscular spasm. My experience in the treatment of fracture is that if muscles are sufficiently controlled they come to rest and cease to struggle, but that if the control is inefficient or intermittent then reflex movements are active, and that all muscles enervated from the same region share more or less in the excitability. I do not believe that the desire to contract is as inherent in muscles as if it were original sin. How commonly we see a knock-knee following a fracture of the lower third of the tibia. This is generally due to the common practice of setting a fracture of the tibia as if it were a straight bone; we place a pad on the inner side of the ankle in such a way as to obliterate the normal curve. But of all fractures which are badly managed that described by Percival Pott is the most common. A distinguished hospital surgeon, who looked after the London police, stated once that he had never known a police officer who had sustained a Pott's fracture return to his full duty. This statement is a notable testimony to the inefficiency of routine hospital treatment, for most of such fractures are taken direct to our teaching centres. As we all know, a Pott's fracture exhibits a dislocation backwards of the foot, together with eversion. We constantly find the unreduced dislocation as an end result; yet this dislocation is never difficult to reduce provided the method has been taught. The reduction of the deformity should be undertaken at the earliest possible moment, although it can often be accomplished by manipulation at any time under three weeks. Every student should be taught that the knee should be fully flexed, the heel pulled forwards, and the lower end of the tibia simultaneously pushed backwards. The reduction is usually accompanied by a click, which is heard and felt as clearly as in the reduction of a dislocated shoulder. The foot should be fixed in inversion. Even if the bones are restored to their normal relationship eversion will recur later unless during standing and walking body weight is deflected to the outer side of the tarsus.

In the upper extremity, how common it is to find a stiff elbow following a fracture just above or through the joint, and this sometimes in spite of complete flexion. Failure to reduce the fracture accurately is generally the cause of this. It is not enough to take hold of the arm and merely to flex it. It should first of all be supinated, then extended and pulled, and while the upper end of the fracture is pushed back, the forearm should be pulled forwards and flexed. A student should be taught this manipulation, for it will save him many a serious dislocation. The application of the internal angular splint is happily becoming less frequent. It is a pernicious method. The advantage of the manipulation I have

described is invaluable to the practitioner, for it is applicable to most fractures of the elbow, and indeed to dislocations also. I could multiply these various types of fractures, but it is sufficient to give these few clinical illustrations. There are, however, other general principles which are commonly ignored, and to which I will refer.

#### AVOIDANCE OF COMPLICATIONS.

First, let me give a word of warning against the growing tendency of the immediate application of plaster-of-Paris. It assumes, as I have said, the immediate and complete reduction of a fracture, which is not always possible. It prevents the intelligent use of pads, and does not allow of inspection and supervision. Unless applied by an expert it often tends to interfere with the vitality of the limb because of circular compression. If put on a limb newly injured it will become slack as soon as the swelling subsides. It does not permit of massage, so often necessary to hasten recovery. In spite of this, circumstances may arise where the application of plaster is the only available procedure. No student should be allowed to leave his hospital until he is familiar with the modern methods of applying plaster. A badly applied plaster often proves a very dangerous splint, and is a common cause of non-union and of pressure sores.

The student is not sufficiently warned against the pressure slough, nor the best ways of avoiding it. A slough may occur in twelve hours or less if plaster is placed over a thinly clad bone, and while developing give rise to nothing more than discomfort. I have known deep sloughs occur without any complaint having been made by the patient. This type, which occurs without pain, is generally the worst, the pressure over bone having benumbed the skin from the first. If, therefore, it becomes imperative to employ pads on such places they should be examined and changed frequently, despite the fact that the patient may be feeling very comfortable.

Another defect in the student's training, if we can consider it as reflected in the practitioner, relates to delayed union and non-union. Granted a fair apposition of non-union rarely occurs. It is generally the result of nervousness and impatience. Some surgeons are never content unless they worry the fractured ends week after week to see how consolidation proceeds. Such procedure is as unscientific as the action of a cook who opens her oven door every five minutes to see how the hot-pot progresses. Until the normal period of completion of consolidation, absolute rest should be ensured. If union is delayed the surgeon should be patient. I have often known a fracture of the shaft of the tibia take many months to unite.

#### AFTER-TREATMENT AND PROTECTION.

Another source of error is to be traced to deficient instruction in prognosis. The student is not taught the length of time restraint should be continued, nor the nature of after-care. Even to-day, textbooks do not instruct him as to when he may reasonably expect complete consolidation. The result is that a patient may leave a surgeon with a limb of normal form and length, and in a few weeks it may be short and crooked. It cannot be too clearly emphasized that a lower limb which can pass the test of a manual examination may completely fail when body weight is superimposed. Adequate protection should, therefore, always be given to a fractured limb when walking is prescribed. These faults in principle and errors in technique are the direct outcome of imperfect instruction, and the student has a just cause of complaint. In spite of a well equipped physiotherapy department attached to the hospital, how few students are able to give intelligent instruction to a masseuse, or to direct a gymnast in treating a deformity, or show an electrotherapist the muscles he should stimulate in order to overcome weakness. The instruction generally given is, "Have your arm massaged," or "Use the faradic current," or "Give exercises to this man." We blame the physiotherapists if they do not carry out the doctor's instructions; we do not dwell on the fact that the doctors—with few exceptions—do not possess the knowledge to instruct. Surely there is some

thing radically wrong with a syllabus which leaves the students ignorant in matters of such practical importance. It is an open invitation to every species of quack.

How few students have been taught to distinguish between a joint which may be moved and one which should be kept at rest—and how many bitter disappointments result from this. How few men know how to handle a fracture; how to hold the broken arm with a minimum of pain; how to feel for crepitation; how to avoid muscular spasm; how to reduce deformity, and, as it has been called, "set" the fracture. A surgeon who is interested in his subject, and knows it, will teach the student more by demonstrating one case than can ever be learnt by the student in personally handling twenty cases in a spirit of adventure. The student should be taught to use his eyes, his measuring tape, and the art of reducing a fracture almost painlessly by postural muscle relaxation. Such an education in manipulation is worth any amount of untutored experience. The rough handling of fractures by the unskilful is an outrage on a patient, and when done in the presence of a student is an extremely bad example.

I might multiply instances in evidence of inadequate tuition, but this is no longer needed. The cry of the practitioners all over the country is, "We have not been taught." It is, I submit, our duty to remedy all this.

It is not my intention to deal with malunited fractures, but it is necessary to emphasize one fact. If the treatment after correction is no better than in the first instance there will be a repetition of the tragedy. A malunited fracture cannot be cured merely by an operation; all the operation can do is to reconstruct the fracture, and a satisfactory result can only occur by the maintenance of the alignment until consolidation of the bone is complete.

#### ORGANIZATION NEEDED: THE FRACTURE CLINIC.

As I have already indicated, the permanent lessons of the war were not concerned solely with the value of certain methods of treatment, but rather with the essential importance of the efficient organization and handling of clinical material. It was made more clear to us abroad than it is even in our general civilian hospitals that the wide field of general surgery could not be creditably traversed by one and the same man. Team work and segregation in many fields of surgical endeavour saved the lives of patients, and the reputation of surgery. This became evident in fractures more than in any other branch of work. I have no hesitation in saying that greater progress was made in the treatment of fractures during the four years of war than had occurred during a generation in our big teaching hospitals. Beginning with complicated and ill considered contrivances, we developed on lines of simplicity to a very efficient goal. The experience we gained then we have to apply now to the problems of civil life. Brilliant achievements in abdominal surgery during the past twenty years have proved irresistible to the imagination of our younger surgeons. The less exciting disabilities of the extremities have been crowded out of the wards and out of their minds.

The treatment of fractures must be placed on a different plane. Our students must be taught, and our teachers must be wisely chosen. In developing a scheme, certain general principles must be agreed to:

1. The necessity for the segregation of in-patient fractures either into: (a) wards under the control of a special surgical unit, or (b) in special wards not allocated to one unit alone.
2. The creation of a special out-patient fracture clinic, to be included with the fracture wards as part of a general scheme. Out-patient fractures should not be dealt with as a separate entity—in other words, their control should be under the surgeon or surgeons in charge of the fracture wards.
3. A surgeon in charge of the fracture department should be a consultant, the director of a unit, and one in whose practice and teaching the treatment of fractures will be maintained during the whole of his active surgical career. If there exists an orthopaedic department, as should be the case in every teaching hospital, the chief of this department should be one of the surgeons in charge of fractures—even if he is not the only one.

In an ideal scheme the fracture wards should form part of the orthopaedic service; this would simplify both the organization and the teaching. It is certain that no real advance in the treatment of fractures will ever take place if the department is placed on a secondary plane, which is inevitable if the system is inaugurated or maintained of leaving it under the control of a junior surgical officer, who makes this position a mere stepping-stone to some other surgical post.

The fracture team should consist of:

1. One or more surgeons, including the orthopaedic surgeon.
2. A senior assistant. This appointment should be well thought out, and only given to a man with special qualification for the post. There should be security of tenure for a period sufficiently long to make him not only expert, but to secure his skill for the training of the students. He should display special interest in the surgery of the extremities, and preferably intend to follow it up. I consider that the success or failure of the department will largely depend upon this appointment. It may be asked, "What is to become of this assistant in after-life? How is he to earn his living? Is there room for fracture specialists in private practice?" My answer is that if the right man is chosen for this post he will almost surely gravitate to orthopaedic work, where his knowledge will be of the greatest service, and form an integral part of his expert education.
3. The third member of the team should be a physiotherapist, preferably the chief of his department. In addition to these there will be the house-surgeons, who attend the clinic as part of their duties, dressers, and clinical assistants.
4. Another most important member of the fracture team should be a sister, specially trained, who should be in charge of the fracture ward. She should remain in undisturbed possession. The care and nursing of fracture cases requires very considerable skill and training, and it is essential that the sister should not be transferred to other departments.

If the fracture ward is under the control of more than one surgeon the first assistant should be in the service of all. He will maintain a salutary rivalry between his various chiefs, which is an important step towards efficiency. I lay the greatest stress upon the segregation of fractures in special wards, even in those hospitals which do not specialize in teaching. It makes for healthy criticism, and often to much-needed introspection. Surgeon A, with a case of shortened malunited femur, will realize his limitations when he sees what Surgeon B can do with a similar injury. Surgeon C may feel that his reputation would be enhanced if he handed over his fractures to a more interested colleague.

#### The Magnitude of the Problem.

What proportion of beds should be put aside for fractures? My friend Mr. Platt of Manchester tells me he has worked it out to be about 10 per cent. In a hospital of 300 beds with five surgical units, each surgeon would direct 60. If the fracture cases are under one control, 35 of his 60 beds would be devoted to them. This would supply an ample field for instruction. Let us assume we have our beds and an expert staff of teachers. What can be done in order that the student may derive full advantage from the scheme?

#### The Plan of Instruction.

In the first place, once or twice a week there should be an out-patient fracture clinic, which all senior students are obliged to attend. At least twelve attendances should be compulsory. No formal lectures are needed, but, instead, a series of clinical demonstrations, in which groups of fractures are collected and compared, and instruction given in relation to diagnosis, prognosis, and end-results. More especially the student should be taught the principles that underlie the prevention of deformity and its correction. The tuition must be direct and simple, most of the time being devoted to the common fractures with which the practitioner is likely to meet. The x-ray department, with the wealth of information it represents, should be in close touch with the fracture clinic. The student should be

taught never to lose an opportunity of obtaining an x-ray photograph, and, above all, endeavour to derive instruction in interpreting it. In 1900 I wrote:

"The advent of the x rays has added immensely to the accuracy of our knowledge and to the classification of our cases, and has saved our patient from much unnecessary and often aimless manipulation. We must, however, beware that we do not paralyse our diagnostic faculties from pure inanition. The Roentgen rays should not usurp every other diagnostic means at our disposal."

I think these words are true to-day. In the fracture clinic measurements and visual impressions as practised by the great past clinicians should be recorded, and comparisons made between the healthy and the injured limb. Thus the student will be taught to diagnose the existence of a fracture, in the absence of a radiogram, with the least possible discomfort to the patient. Indeed, in the ideal fracture clinic the groan of an adult and the tears of a child should be a rare event. In this clinic will be found the common deformities so often associated with simple fractures. The lessons he will learn from these will be of incalculable service to the student in later life.

The student should not leave the fracture clinic without having practical experience, not merely of putting on plaster bandages, but applying them artistically and well. Nor should he be certified until he has a sound working knowledge of the application of splints.

#### *The Choice of Splints.*

At this stage I should like again to emphasize the urgent necessity there is for each hospital to scrap its useless splints and retain for teaching purposes only those of known efficiency. Bearing on this point, I will tell you an experience I had during the war. An army surgeon took me into a large shed the walls of which were covered by hundreds and thousands of splints of every type and age. I stood positively bewildered. There were hardly any of them I knew how to use. I asked the very intelligent officer who had charge of them what use could possibly be made of them. He knew the tragedy as he told me, "They will all be sent to the front when the slaughter begins." I can imagine the utter hopelessness of even the most experienced surgeons in the presence of such futile implements. Hospital staffs should, from time to time, meet and select the most useful—and they are generally the simplest—splints, and no student should graduate unless he has completely mastered their correct application. Furthermore, in order to simplify the training and to stabilize the examination of the students, this idea could be extended by the formation of a committee, representative of all teaching hospitals, to decide upon the best type of splint.

This would be of immense service in a national emergency, and would save the student much waste of time. It is a harrowing thought that many thousands of lives would have been saved abroad if every surgeon had been taught to apply splints correctly and expeditiously, and if only those splints had been at hand whose efficiency had been tested. We were able to be of considerable help in this matter to our American colleagues, who learnt from our mistakes, and they published an illustrated little handbook of splints, simple in construction and effective in use, which every surgeon had to master thoroughly. Instruction in a fracture clinic such as I have outlined would have met the urgent need in the great war, and such dire experiences as we encountered in its early stages should leave an indelible impression upon our mind and conduct.

The instruction carried out in the out-patient department should next be continued in the fracture ward, where the best methods of dealing with the recumbent cases could be taught.

#### CONCLUSION.

I venture to suggest that the scheme I have formulated is neither difficult in conception nor revolutionary to bring into effect. In our large teaching hospitals it means merely a practical readjustment of studies. There is sometimes a natural inclination on the part of the general surgeon to resist what he fears to be an encroachment of specialism. This, I am happy to think, is less evident than in days gone by. There is no more circumscribed a specialty than that of the surgery of the abdomen. That an expert abdo-

minal surgeon often appears in other parts does not alter the fact. Many men who have excelled in the subject of their choice have told me they would be glad to hand over their fracture cases, but, they ask, "To whom?" Without a fracture department there is no remedy for them. There can be little doubt that many surgeons would, to their advantage, prefer to leave such cases in the hands of a fracture team than be held responsible for mistakes, which are bound to be made by inexperienced juniors. Even if they did not hand their cases over to a colleague, they would welcome the assistance of an expert first assistant. The average hospital surgeon takes neither pride nor scientific interest in the treatment of fractures. He knows it himself, his house-surgeons know it, and so do the students. Wherein and with whom lies an advantage? No! it is not a mere matter of the encroachment of specialism, but a call to our sense of proportion and sense of duty. Whether we use the term "specialism" or not, there is no mind so comprehensive that it can keep pace with all the requirements of modern surgery.

Another criticism likely to be levelled against this scheme is that the student curriculum is already too overcrowded. This does not bear examination. We do not wish to crowd the student's mind; on the contrary, we desire to simplify and clarify his instruction. By securing expert men to teach we exclude much waste of energy. His education becomes intensive instead of being diffuse and desultory. He is taught what is necessary and practical by teachers who have a real knowledge and interest in their subject. When we find students crowding the operating theatre on every opportunity, watching work they will probably never be called upon to do, and this for years, we appreciate how valuable time is wasted. It is doubtless necessary that they should know something of intricate and rare cases, but the out-patient department affords them a better equipment in after-life than academic lectures, the matter of which they can equally well glean from textbooks.

Another objection that may be urged is that our hospitals are already too crowded, and that the so-called chronic cases should not be allowed to exclude the acute ones. This is but poor comfort to a young working man sent off to a Poor Law infirmary, with a wife and family dependent upon him. It is inefficient treatment and neglect which transform a simple fracture to a chronic deformity. It is far better for our hospital authorities to say, "We are not prepared to treat fractures," than that they should take on responsibilities which they cannot meet. The responsibility is not met by sending a fracture of the femur from their door directly to a Poor Law infirmary, unless they know that its staff and equipment can meet the indications. On the contrary, they are very much to blame. We cannot disguise the fact that great numbers of adult cripples are manufactured by want of adequate provision. If our city hospitals admit they cannot cope with the problem for want of beds, wards should be procured in Poor Law infirmaries or other institutions. These wards, however, should be fully staffed and equipped, and brought into close association with our teaching centres. But whatever the arrangement, the student should have the full benefit of it. There can be no justification for any system which adds to the complexity, and not to the relief, of our cripple problem.

My early education with H. O. Thomas brought me into close contact with every type of cripple due to neglected fracture which he was called upon to treat. Experience since that time has led me to the conclusion that the same old mistakes occur now as they did then, and for this reason I have tried to indicate a remedy.

I earnestly hope that it will not be thought I have betrayed any spirit of hostility in this address. Nothing has been further from my mind. My aim has been to express in a temperate manner opinions which are shared by many distinguished hospital surgeons. I have spoken plainly, as I know you would have me do, but it has been my endeavour to understate rather than to exaggerate the defects of our present system. May I hope that my remarks will be received in the friendly spirit in which they are offered. Should they be the means of opening a new chapter in the organization and handling of fractures I shall rejoice, for most assuredly a blot on British surgery will thereby be erased.

# A STUDY OF THE HAEMOCLASIC CRISIS TEST FOR LIVER FUNCTION:

WITH SPECIAL REFERENCE TO THE LEUCOCYTIC  
CHANGES.

BY

A. F. BERNARD SHAW, B.A., M.D., F.R.C.P.I.,

LECTURER IN PATHOLOGY, UNIVERSITY OF DURNAM COLLEGE  
OF MEDICINE, NEWCASTLE-UPON-TYNE.

(From the Pathological Departments of the College of Medicine and  
Royal Victoria Infirmary, Newcastle-upon-Tyne.)

In 1920 Widal, Abrami, and Ivanescu<sup>1</sup> described a new test for liver function under the title "digestive haemoclasis." From experiments on dogs they claim to have proved that during protein digestion the peptones absorbed from the intestine are arrested by the liver ("proteopexic function") and do not reach the general circulation. In the normal dog the protein meal excites a digestion leucocytosis. On the other hand, intravenous injection of peptone into the systemic circulation in a fasting dog immediately provokes a "haemoclasic crisis"—namely: (a) leucopenia with a relative lymphocytosis; (b) fall of blood pressure; (c) hypercoagulability; (d) decrease of the refractometric index of the serum. These data were then applied as a clinical diagnostic test for hepatic insufficiency in man, on the theory that in liver disease the proteopexic function is impaired or destroyed and allows a haemoclasic crisis to develop after a protein meal. In practice the test is extremely simple, serial leucocytic counts being all that are required according to Widal. Estimations of blood pressure, coagulation, and refractometric index are not essential for diagnosis.

Preliminary starvation of the patient is essential (five hours at least). A leucocytic count is done and the standard test meal, which is 200 c.cm. of milk, is immediately given. The counts are repeated every twenty minutes for one hour. In liver disease a leucopenia of 30 to 70 per cent. with a relative lymphocytosis develops and reaches its maximum in twenty to forty minutes after the test meal. A leucocytosis appears about one and a half hours after the milk. Associated with the leucopenia there is a fall of blood pressure (10 to 20 mm. Hg), hypercoagulability, and a fall in the serum index. With 8 grams of dried casein (=200 c.cm. milk) the reaction is intense and precocious. Widal found that in 39 cases of definite liver disease 38 gave a positive reaction. He claims that the test is extremely sensitive, being capable of detecting "latent hepatism" and also liver damage due to salvarsan compounds. It is negative in alcoholic jaundice. In 11 normal persons the test was negative; in 9 a leucocytosis appeared and in 2 no appreciable change; in all the blood pressure rose 10 to 30 mm. The reaction was also negative in diseases of the alimentary tract and in other conditions in which the liver was intact.

In criticism of Widal's work it may be said that although the accuracy of the test depends entirely on the technique employed in counting and the interpretation of the results therefrom, yet he omits to describe his technique and gives no protocols of his counts. Only one count is done before the test meal, and this is accepted as a fixed point on which to interpret the subsequent variations; but this assumes that in a starving person the number of leucocytes is either constant or if fluctuations occur they are so small as to introduce no serious error. The extensive literature provoked by the test is open to the same criticism, and is itself sufficiently conflicting to throw doubt on the value of the reaction as a means of clinical diagnosis in hepatic insufficiency.

## Observations on the Haemoclasic Crisis.

My own observations refer to the leucocytic changes in (1) cases of liver disease, including alcoholic jaundice and persons treated with novarsenobillon (N.A.B.), after 200 c.cm. of milk; (2) normal persons after 200 c.cm. of milk; (3) normal persons fed with substances other than milk; (4) normal persons after the local application of cold; (5) normal persons during physiological rest. Blood

pressure readings were taken in some cases. No records were made of coagulation or serum refractometry.

**Conditions of Experiment and Technique.**—All subjects were starved of food and fluid overnight. To eliminate possible effects of periodicity, temperature, and exertion the zero count was made between 9 and 9.30 a.m. in a room of uniform temperature. Patients were examined in bed; normals were kept in a position of complete rest for at least half an hour before zero count.

**No. 1. Leucocytic Crisis. Male. 54 years. Confirmed post-mortem.**

Time	0'	20'	40'	70'	Remarks
Total leucocytes	4450	4600	3700	3700	Leukopenia = 17% in 40'

**Differential Count.** Relative increase of polymorphs by 6% at leukopenia with relative and absolute decrease of lymphocytes.

**No. 2. Obstructive Jaundice. Female. 57 years. Post-mortem—cancer found of pancreas; obstruction of common bile duct; metastases in liver.**

Time	0'	20'	40'	70'	Remarks
Total leucocytes	4150	4700	3450	5400	Leukopenia = 17% in 40' Leucocytosis in 70'

**Differential Count.** Slight and irregular oscillations throughout but no evidence of lymphocytosis.

**Blood Pressure.** Rise of 6 mm. at leukopenia otherwise no change.

**No. 3. Catarrhal Jaundice. Male. 24 years. Recovery.**

Time	0'	20'	40'	70'	Remarks
Total leucocytes	7200	6300	5950	7350	Drop jaundice of Leukopenia 17% in 20'
"	8050	8200	8000	8300	Slight jaundice, Leukocytosis in 70'
"	7100	6900	7500	7750	Jaundice, Urine—no bile constituents, Leukocytosis in 70'
2 months later	6500	5150	7300	6750	At work 2 months. No jaundice, Urine—no bile constituents, Leukopenia = 21% in 20'

**Differential Counts.** On 13" and 24" days showed irregular oscillations but no lymphocytosis.

**No. 4. Alcoholic Jaundice. Female. 65 years. Case-2, 34 years; increased frequency of red cells. Urine—excess of urobilin. No other bile constituents. Two tests on consecutive days.**

Time	0'	20'	40'	70'	Remarks
Total leucocytes	9000	7050	8200	8500	Leukopenia = 22% in 20'
"	9000	7350	8150	7150	Leukopenia = 16% in 20'

**Differential Count.** There was a slight relative lymphocytosis (4%) coinciding with leukopenic phase in first test.

**No. 5. Jaundice after N.A.B. Male. 26 years. Primary syphilis. Course = 2.2 grms. N.A.B. Jaundice appeared 6 months later.**

Time	0'	20'	40'	60'	Remarks
Total leucocytes	4100	3300	3650	3600	Drop jaundice. Leukopenia 16% in 20'

**Blood Pressure.** No appreciable change.

**No. 6. Jaundice after N.A.B. Male. 27 years. Course = 2.2 grms. N.A.B. Jaundice and ascites appeared 2 months later. Post-mortem—advanced, subacute atrophy of liver. Tested three times; the second test 4 days after the first and the third 16 days after the second.**

Time	0'	20'	40'	60'	80'	Remarks
Total leucocytes	2300	2250	1600	1600	1800	Leukopenia = 30% in 40'
"	2300	1500	1450	2250	2200	Leukopenia = 35% in 40'
"	3050	2400	2450	2750	—	Leukopenia = 21% in 20'

**Differential Counts.** In first test a relative increase of polymorphs by 13% at maximum leukopenia. In second test an absolute and relative decrease of polymorphs and a relative lymphocytosis (7%) at time of maximum leukopenia. **Blood Pressure.** Maximum depression was 4 mm. and did not coincide with leukopenia.

**No. 7. Primary Syphilis. Male. 34 years. Primary chancre. N.A.B. Course = 2.2 grms. N.A.B. never had jaundice.**

Time	0'	20'	40'	60'	70'	Remarks
Before treatment	6550	5100	5800	—	5850	Leukopenia = 22% in 20'
3 days after 0.45 grms N.A.B.	6650	6650	6500	—	6750	No change
1 day after 1.5 grms N.A.B.	6550	5500	6200	5450	—	Leukopenia = 16% in 20'

Blood was taken from the ear with the usual precautions. Preliminary experiments with the Thoma-Zeiss counting chamber showed that this apparatus is subject to considerable error. All readings were made with the Fuchs-Rosenthal counting chamber and Thoma-Zeiss leucocytic pipette. The blood was diluted 1 in 10; it was shaken vigorously for three minutes. The cells on ten squares were counted, this number being one-fifth of the total in 1 c.mm. of undiluted blood. The cover-glass designed by Allport<sup>2</sup> was used; owing to its thickness (4 mm.) there is no risk of bending and it can be placed in position with formation of the Newtonian rings before the counting chamber is charged. The error with this technique does not exceed 2 per cent., but variations of less than 10 per cent. from the zero count were accepted.

as indicating no alteration in the number of leucocytes. The zero count was made immediately before ingestion of the test meal. For differential counts 500 cells were registered.

#### The Reaction in Liver Disease and after *Novarsenobillon*.

Observations were made in 7 cases with 200 c.cm. of cold milk, the maximum leucopenia recorded within one hour being taken as a positive result. The clinical details of the cases and the results of the test were as shown in the protocols (p. 914).

Examination of the protocols shows that in 4 cases (Nos. 1, 2, 5, 6) of obvious liver disease the test gave consistent results as indicated by a leucopenia of 17 to 36 per cent. in twenty to forty minutes, although in the severe and fatal case of obstructive jaundice (No. 2) the reaction is not very convincing, an echelon curve being present, which Widal regards as indicating improvement in liver insufficiency. The serial tests in catarrhal jaundice (No. 3) are conflicting. There is a positive reaction during the period of severe icterus, followed by a negative at a time when it is extremely doubtful if the liver function has been restored to normal, while two months later haemoclasis recurs in the absence of any clinical or urological signs of hepatic disturbance. The attempt to assess the value of the test during arsenobenzol treatment (No. 7) was frustrated by the presence of a positive reaction before treatment was commenced and in the absence of any signs of impaired liver function. The positive result in alcoholic jaundice (No. 4) is contrary to Widal's statement that haemoclasis is absent in this disease. Although continual fluctuations appeared in the differential counts there was no evidence of a consistent lymphocytosis, and in none of the cases in which blood pressure readings were taken did a hypotension develop. The results, on the whole, discount the value of the test as a means of diagnosis in liver insufficiency, and further investigations have been directed to elucidating the mechanism and significance of the leucocyte variations in the haemoclasic test by a study of the reaction in normal persons subjected to various stimuli.

#### The Reaction in Normal Persons.

The majority were student volunteers; only those were accepted who gave no history of liver disease and in whom the urine contained no bile constituents. The total examined numbered 23, of whom 8 were tested once and 15 two or more times, usually on successive days. The test meal was 200 c.cm. of cold milk, and the result was registered on the percentage variation in one hour. As the leucocyte response varied not only in different persons but sometimes in the same person from day to day, it was necessary to divide the results into four groups—namely:

(1) leucopenia, (2) no effect, (3) leucocytosis, (4) paradoxical. The protocols of these are shown in Tables I, II, III, and IV. The total examinations made were 40, and taking these as a basis there was a leucopenia 20 times (50 per cent.), leucocytosis 7 times (18 per cent.), and no effect 13 times (32 per cent.)—proportions which correspond fairly closely with the results of Schiff and Stransky<sup>3</sup> in infants. Consequently alimentary leucopenia is not peculiar to infancy, as suggested by Glazer,<sup>4</sup> but appears to occur as frequently in adults.

In the leucopenic series the extent of the fall varies from 10 to 28 per cent., often corresponding in the same person on consecutive days (Nos. 2, 3, 4, and 102). Usually the fall reaches its maximum in twenty to forty minutes, but in some cases the decline has set in or even reached its apogee ten minutes after the milk. Occasionally it is evanescent and only registered at one examination. The subsequent course of the curve is also variable, the count returning to the initial level or the fall persisting. The appearance of a leucocytosis after an hour is inconstant. Obviously in this group the curve is quite comparable in its general characters to that in liver disease, and it can be concluded that many normal persons react with a haemoclasic leucopenia. This agrees with Eisenstadt,<sup>5</sup> who found a leucopenia in normal adults (number not recorded) after 200 c.cm. of milk, in spite of the fact that he accepted a variation of less than 17 per cent. in the count as due to experimental error. However, in 4 normals (Zehnter<sup>6</sup>) and in 3 normals (Mauriac and Ragot<sup>7</sup>) there was no leucopenia after

20 c.cm. of milk. Unfortunately the authors do not state what other change took place. Whether the leucopenia can be attributed to the milk at all seems extremely doubtful. In 32 per cent. of my tests the count remained more or less constant for an hour or longer, and in several cases reacting with leucopenia the response to a second test showed that the milk had either no influence or appeared

to produce a leucocytosis. Similarly it is difficult to accept the view that the milk produces a "digestion" leucocytosis—that is, a chemiotactic response to the products of digestion. Only in 18 per cent. of tests did a rise, which sometimes was evanescent, develop in one hour. The leucocytosis which Widal found to appear in about one and a half hours is not confirmed by my protocols, as the results in seventy to ninety minutes are quite variable—a rise only occurring in about half the cases. If the rise represented a true reaction to the milk products absorbed during digestion it should appear in every normal person within a definite period of time. Its absence cannot be attributed to the small amount of milk given, for in 6 normal persons fed with 400 c.cm. the leucocytic response was similar to that following half the amount. Moreover, the times selected for doing the counts

## THE HAEMOCLASIC TEST FOR LIVER FUNCTION.

THE BRITISH  
MEDICAL JOURNAL

being arbitrary, it is difficult to avoid the impression that the oscillations are often more rapid than the observations indicate, and possibly the results in some cases might have been different if the counts had been made at shorter intervals, though technically it was impossible to do this and ensure accuracy.

In 10 cases selected from the three types of response the differential count revealed qualitative changes similar to those found in liver cases—that is, there was no schematic alteration. The blood pressure taken in 4 cases (2 leucopenia and 2 leucocytosis) showed oscillations of a few millimetres bearing no relation to the leucocytic curve. However, there are some investigators who find that leucocytosis does develop in normal persons. Holzer and Schilling<sup>8</sup> say that a digestion leucocytosis follows a normal amount of carbohydrate in normal adults with 200 c.cm. of milk, and in every case a leucocytosis appeared, reaching its maximum after an hour. All the curves were surprisingly similar in character, and though the first count was made half an hour after the test meal a fall below the initial count was never registered. C. M. Wilson<sup>10</sup> also records a leucocytosis within one hour after 200 c.cm. of milk in 30 normal students. Nevertheless, in my evidence that the ingestion of 200 to 400 c.cm. of milk produces a specific effect on the leucocytic content of the peripheral capillary blood, either in the form of a "digestion leucopenia" or a "digestion leucocytosis."

CHART A. Leukocytic curves after 200cc. milk and 400cc. distilled water in same person.

The leucocytic variations are quite independent of the ingestion of food or fluid in the amounts given, and do not represent either a response to any chemical stimulus provided by the products of digestion or the effect of blood dilution following absorption of fluid.

## The Reaction to the Local Application of Cold.

It is generally thought that the external application of cold, such as a cold bath, produces a leucocytosis. But Widal, Abrami, and Brissaud<sup>12</sup> maintain that exposure to cold is followed by a haemoclastic shock identical with that occurring in hepatic insufficiency. In dogs immersed in a bath at 2-3° for fifteen to forty-five minutes the crisis developed in ten to fifteen minutes from the moment of immersion and persisted for half an hour to an hour. Tinel and Sautenoise<sup>13</sup> say that after freezing the finger with ethyl chloride for a few seconds there is an immediate fall in the leucocytic count by 2,000 to 4,000, but whether this occurs in the peripheral circulation generally or only in the domain of application is not made clear by the authors. On the other hand, Jolly and Saragea<sup>14</sup> working with rats, found that leucopenia followed exposure to hot air. In my experiments the arm was immersed for twenty-five minutes in a water-bath at 80° C., a leucocytic count having been done previously from the finger. At the end of twenty-five minutes another count was done with the arm still in water; subsequent counts were done locally—that is, from a finger of the

## The Reaction in Normal Persons to Other Substances.

1. Distilled Water.—Under usual conditions of experiment 7 normal adults were given 400 c.cm. of cold distilled water. The results (Table V) show that one case reacted with a rise which reached its maximum of 23 per cent. in forty minutes, and in 6 cases a leucopenia of 11 to 32 per cent. developed in twenty to forty minutes. The differential counts in 4 cases gave similar results to those obtained in the milk cases. Evidently there is no essential difference in the response of normal persons to milk and water, as both substances give contradictory results and the curves are similar in their degree and periodicity of variation. There can hardly be any question of a chemical

immersed limb. Percentage variations were reckoned on the alterations appearing between zero and up to one hour from the time immersion ceased. Six normal adults were tested (Table VI). Three reacted with a leucocytosis, two with leucopenia, and in one there was no appreciable change. In 4 cases (Nos. 54-57) the differential counts revealed no consistent alterations. It is evident that under the conditions of experiment employed the local application of cold has no specific effect on the number of leucocytes—the cases falling into the three categories which have been described in connexion with alimentary stimulation. The results also appear to eliminate the possibility of the milk

action as the cause of the leucocytic fluctuations following distilled water, and blood dilution is eliminated by the development of a rise in Case 25, and also by comparing the reaction to 200 c.cm. of milk and 400 c.cm. of distilled water in the same person. This was done in 4 cases (Nos. 10, 12, 13, 14). All reacted with a fall to both substances, but in Nos. 10 and 13, the comparative curves of which are shown in Chart A, the fall was greater with milk than with water. These results agree with the work of Moutier and Racht,<sup>11</sup> who tested 10 persons with distilled water. A fall followed in 6 and a rise in 4, while in 9 of the cases the milk curve ran parallel to the water curve.

or distilled water, which were given cold, exerting any specific influence on the leucocytic count by means of their low temperature.

#### Leucocytic Variation during Physiological Rest.

The conflicting results obtained suggest that there must be some other factor wholly or partly responsible for the oscillations observed after the various stimuli used. It has already been said that Widal—and indeed nearly all writers on the subject of haemoclasis—has assumed that during physiological rest the number of leucocytes in the peripheral blood remains practically constant until the alimentary or other stimulus is applied. Consequently they have accepted a single pre-test count as representing a fixed point, subsequent variations from which are held to be the response to the stimulus.

But my observations show conclusively that leucocytic equilibrium is not necessarily maintained in the absence of alimentary stimulation. I have examined 10 normal adults during physiological rest over periods ranging from eighty minutes to two hours and twenty minutes, the protocols of which are shown in Table VII. To make the readings comparable to my other observations the zero count is taken as a fixed point and the percentage variation calculated during the succeeding hour. If, however, the difference between the maximum and minimum counts over the whole period of observation is taken, the variation, in some cases, would be greater. The protocols show that during the first hour a fall occurred in 3 cases, a rise in 1 case, and in 6 cases the leucocytic content remained stable. Therefore each case falls into one of the three groups found after stimulation. Moreover, when oscillations occur during physiological rest, they are similar in rapidity and extent to those following milk, etc. This is confirmed by comparing the "rest" curve and "stimulation" curve in the same person, which was done in 7 cases. In 4 cases the milk curve and the "rest" curve ran parallel in 2, while the distilled water curve and the rest curve were similar in one of the three cases tested. This is illustrated in Chart B. Evidence of

during physiological rest there is a leucocytic curve composed of large waves, which in their course show subsidiary variations, the latter sometimes exhibiting considerable oscillations. It is obvious, therefore, that the single count before stimulation cannot be accepted as necessarily indicating a state of equilibrium. Frequently it is only an index of the number at the particular moment, and represents nothing more than a point on one of the oscillations of the physiological rest curve.

Furthermore, a study of the total series of pre-test counts in my observations indicates that the particular result obtained in the haemoclasic test depends on the phase of the normal curve at the moment of test. The

lowest counts were between 3,000 and 4,000, the highest between 8,000 and 9,650, and these represent the extreme limits of undulation in the series of normal persons. In every count above 8,000 the test was followed by a considerable fall—that is, at the time when the curve was presumably at its zenith—while the variable results

following low and intermediate counts appear to be due to the particular direction pursued by the curve during the period of test. But my observations also show that phases of equilibrium do occur, and are associated more especially with relatively low counts. Possibly this may explain why Friedemann and Nubian<sup>13</sup> failed to obtain a fall in cases of leucopenia due to various causes and in which they concluded a permanent state of haemoclasis existed. Even assuming that the stimuli I have used do influence the number of leucocytes, the result must be considerably modified by the physiological variations, and it would be necessary to eliminate the latter to arrive at the effect of the stimulus. But it has been shown that the two curves are so similar as to be practically identical, and therefore I think that the stimuli employed have no effect on the number of leucocytes in the peripheral blood—the variations recorded in the experiments being nothing more than the fluctuations of physiological rest. Kobryner's work confirms this, for he has shown that food, fluid, movement, etc., do not influence either the total leucocytic curve or its phases. Consequently I think that there is neither a "digestion leucocytosis" nor a "digestion leucopenia," the results recorded as such in the literature on haemoclasis being simply the expression of the phase of the normal curve at the time the test is done—a descending phase being registered as a leucopenia and an ascending one as a leucocytosis.

CHART B. Leucocytic curve during rest compared with curve after 200 cc. milk or 400 cc. water in the same person.

oscillation during physiological rest also appeared in persons subjected to the haemoclasic test. In all my protocols only one pre-test count has been recorded, but in 7 cases two counts were made at intervals of fifteen to twenty-five minutes, the test meal being given immediately after the second count. The percentage difference between the two counts in the 7 cases was: -13%; -10%; -9%; +16%; -7%; +4%; +30% (the minus sign indicates that the first count was the higher of the two; the plus sign the reverse). If the first count had been accepted as representing the leucocytic content immediately before the test meal the results would have been altered in 5 of the 7 cases.

Fluctuation in the number of leucocytes apart from food has been noted by several observers. Mauriac and Cabonat,<sup>14</sup> examining the leucocytic variations in two normal adults, not in absolute physiological rest, over a period of fifteen hours at intervals of thirty minutes, found considerable and sudden oscillations in the count. Servantie, Panzatz, and Monod,<sup>15</sup> in one normal person during starvation, record fluctuations of 2,000 to 3,700 in counts done every ten minutes. Kobryner<sup>17</sup> concludes, from numerous observations made over long periods, that

1. Widal's haemoclasic test for liver function lacks a theoretical basis, and in practice is of no value in the diagnosis of hepatic insufficiency.

2. During physiological rest the number of leucocytes in the peripheral blood is subject to considerable and rapid fluctuations, though there are phases in which a state of equilibrium exists.

3. There is no evidence that the ingestion of milk, casein, butter-fat, and distilled water in certain quantities, or the local application of cold, influences the leucocytic content of the peripheral capillary blood, the oscillations following these stimuli being the same as the physiological variations during rest.

4. The phenomena of "digestion leucocytosis" and "digestion leucopenia" described in connexion with the

haemoclastic test are simply physiological variations and not the response to ingestion of foodstuffs.

5. The conflicting conclusions as to the value of the haemoclastic test arise from a failure to recognize that normally the leucocytic content is in a state of flux, and consequently that a single count made before the test does not represent a state of equilibrium.

My special thanks are due to the British Medical Association for a grant, through the Science Committee, to defray the expenses of this work.

## ACTINOMYCOSIS OF THE PLEURA.

AN ACCOUNT OF TWO CASES, WITH PATHOLOGICAL FINDINGS,

BY

D. WELLS PATTERSON, O.B.E., M.B., M.R.C.P.,

AND

F. J. NATTRASS, M.D., M.R.C.P.,

ASSISTANT PHYSICIANS, ROYAL VICTORIA INFIRMARY,  
NEWCASTLE-ON-TYNE.

THE two cases here recorded differ considerably in type, but the clinical features are worthy of study, as also are certain considerations which the cases raise as to the vexed question of the etiology of this disease.

### CASE I.

A woman, aged 20, an assistant in a drapery shop, had always lived in Newcastle. In October, 1921, she complained of pains in the back and general malaise, and about a fortnight later was laid up with "pleurisy" on the left side and pain in the left shoulder. She appeared to get over this, but, not gaining strength, reported to her doctor late in November, and was found by him to have a coarse pericardial friction rub over the base of the heart. She was seen in consultation with Dr. S. Worthington on December 10th, on account of the development of a lump above the left breast. She was pale and somewhat hectic, had a temperature of 100° F., and a pulse of 120. There was an oval swelling about half the size of a hen's egg in relation to the anterior end of the second left rib and second interspace. The swelling was tender, elastic in consistency, not red and not hot; the skin could be moved freely over it, but it was fixed to the deeper structures. There was no pulsation, nor impulse on coughing. Immediately under the swelling there was some diminution of the breath sounds and of the vocal resonance and fremitus, otherwise there were no abnormal signs in the lungs. At the right border of the sternum, in the second and third interspaces, a well marked systolic bruit was audible, the characters of which suggested that it was exocardial. The heart appeared normal in size and position, and there were no other murmurs. Nothing abnormal was found in the other organs.

No definite diagnosis was made and the case was admitted to hospital. Slight fever continued, and the lump gradually increased in size. At the end of a fortnight the lump had doubled in size, and the skin was becoming stretched over it and red in places. The swelling was then explored with a hypodermic syringe, and a little blood withdrawn, but no pus. The site of the needle puncture failed to heal, and within forty-eight hours began to discharge typical oily pus, containing opaque greyish-white granules. Stained specimens revealed the branching mycelia of actinomycetes, and there was also definite evidence of clubbing. No other organisms were found, and pure cultures were obtained anaerobically in 2 per cent. glucose agar, growth being obtained in all of six tubes inoculated. The organism also showed feeble powers of growth under aerobic conditions, two colonies developing on the surface of one of two agar slopes inoculated. A few spores occurred in the stab cultures on the fourteenth day.

The swelling continued to increase rapidly in size, and discharging sinuses appeared in several places; the breast became invaded, and the appearance shown in the photographs was gradually assumed. Surgical intervention was discussed, but abandoned by the surgeons in view of the evidence of involvement of the

FIG. 1.—Early stage.

mediastinal tissues. As alternatives various lines of treatment were followed, namely—

1. Ionization of the growth with potassium iodide.
2. An autogenous vaccine of the streptothrix was prepared from the discharge and administered in increasing doses for many weeks.
3. Potassium iodide was given by the mouth in large doses for several months: 60 grains three times daily were taken for a week at a time, followed by four days without the drug. No signs of iodism appeared at any time.
4. In place of ionization a long course of x-ray treatment was given. In all eighty-one applications were given with a 10-milliamperé Coolidge tube and a 2 mm. aluminium filter, the tube distance being 12 inches.

None of these measures had any appreciable effect, the local condition remaining more or less stationary while general cachexia and emaciation advanced. Considerable glandular enlargement appeared in the left axilla, and two additional swellings appeared, one behind the right ear and one at the lower end of the left scapula. The former burst and discharged pus and then healed; no actinomycetes was obtained from the pus. The latter also broke down, and continued to discharge a small amount of pus. Gradually dullness developed over the greater part of the left lung and numerous crepitations were heard; immediately beneath the growth breath sounds were absent. For several months remittent pyrexia of moderate degree continued, and by January, 1923, the patient's condition was desperate. The spleen became enlarged, the anterior edge descending a handbreadth below the costal margin; the lower edge of the liver reached to the umbilicus. The urine contained a considerable amount of albumin, and there was intermittent diarrhoea. Cough, which had been almost entirely absent, increased a little, but there was very little sputum throughout.

Blood films showed secondary anaemia and a slight polymorphonuclear leucocytosis. Oedema of the left upper limb developed, and death occurred on March 8th, 1923.

Post-mortem Examination, March 9th, 1923 (Dr. A. F. Bernard Shaw).

On reflection of the skin containing the growth a wide area of suppuration was found extending from the left breast, the pus being green and odourless; the suppuration involved all the tissues of the chest wall, and the periosteum of the ribs was stripped and the bones eroded; the necrotic tissues were soft and ochre-yellow. There was gelatinous oedema of the anterior mediastinum, and the pericardial sac was obliterated by adhesions, which were not very dense. The left pleural sac contained abundant loculi of greenish pus, and the rest of the sac was obliterated by dense adhesions. The left lung was collapsed and airless, but contained no actinomycotic lesions. The glands at the root of the right lung were congested, and there was a small area of invasion of the hilus of this lung by the actinomycotic process. No other evidence of actinomycosis was found throughout the body. Though the liver and spleen were markedly enlarged, neither these organs, nor the heart or kidneys, showed naked-eye evidence of amyloid change, and the iodine test for amyloid degeneration was everywhere negative. Smears from the pus in the left pleura showed numerous streptothrix colonies.

### CASE II.

A shipyard labourer, aged 42, was admitted to the Royal Victoria Infirmary complaining of "abscesses" over the right lower ribs, which had been present for three months.

History.—The patient stated that he had an attack of pleurisy six months before admission and that he had never been well since. At first he was off work for five weeks, and on attempting to start again he developed a second attack of pleurisy. Some time after this second attack the skin condition commenced with

FIG. 2.—Later stage.

what he described as a small blister. He had a troublesome cough at night, but said that he had been troubled with his chest for about sixteen years since an attack of pneumonia.

**Condition on Examination.**—The patient was very thin, with a tall complexion, and the fingers were clubbed. A little to the right of the lower end of the sternum, and extending from the level of the fourth rib to the seventh right intercostal space, was a raised, livid patch of very firm consistency. The surface was glazed and somewhat nodular, with here and there small circular points of superficial necrosis from which a little thin yellow pus could be squeezed. A similar but smaller lesion was situated over the eighth right intercostal space in the mammary line, and a larger lesion measuring 13 by 6 cm. extended over the right costal margin.

**Right Lung.**—Anteriorly the lung was emphysematous. Posteriorly there was dullness on percussion from opposite the fourth dorsal vertebra and increasing towards the base of the lung, where the note was quite flat. The area of dullness, with no breath sounds over the extreme base, vocal resonance was greatly diminished. The left lung was generally emphysematous but fluid until a fortnight before death, when some purulent blood-stained fluid was drawn off from the right pleural sac. At first repeated examinations of the pus from the skin nodules showed nothing, but about a fortnight after admission streptothrix filaments, staining poorly, were discovered. No granules were found to the discharge at any time.

**Progress.**—From 90 to 100 grains of potassium iodide were given daily, and the skin lesions were treated at first with antiseptic dressings and later painted with Gram's solution frequently during the day, but little or no beneficial effect was to be noticed. A month after admission to hospital the patient developed acute pleurisy over the base of the left lung. Later he began to cough up a considerable amount of green purulent expectoration, but no streptothrix could be found on examination of the sputum at any time. The progress of the case was steadily downhill—a swinging temperature developed, the abdomen became distended and tense, there was considerable enlargement of the inferior epigastric vein on the right side, coma set in, and the patient died three months after admission to hospital.

**Post-mortem Examination (Dr. A. F. Bernard Shaw).**  
There was dense thickening of the right pleura, which, on being separated, revealed slimy green pus which had perforated the diaphragm, passed behind it and spread along the spine. The right lung was collapsed and showed moderately large bronchiectatic cavities. The bodies of the ninth and tenth dorsal vertebrae were covered with pus and there was some superficial erosion of the bone. There was a pyaemic abscess in the liver, two abscesses in the spleen, two abscesses in the right kidney, and one in the left kidney. Under the left cerebral cortex five abscesses containing slimy green pus were found and one abscess under the right cortex. The right occipital lobe was destroyed by a similar abscess. Streptothrix in thread form was found in all these abscesses, and was especially abundant and characteristic in the pus from the brain.

#### DIAGNOSIS.

It is clearly important to bear in mind the possibility of this disease in the case of a lump of obscure origin in any part of the chest wall. The appearances may suggest tuberculosis of a rib, sarcoma, gumma, etc., and it may be possible to decide the diagnosis by exploratory puncture, followed by microscopic examination or culture. In our first case the typical granules were numerous and the organism was easily obtained and isolated in pure culture; in the second case no granules were seen, and the organism was only found after many examinations, and never in the sputum, though the lung lesion was extensive. This difficulty in isolating the organism has been encountered by many observers, some of whom would exclude from the category of actinomycosis any case in which granules are absent. While there are no doubt different types of mycelial infection, the presence of branching filaments in a typical lesion appears to us to justify the diagnosis from a clinical point of view.

#### MODE OF INFECTION.

Evidence is accumulating against the view, originally put forward by Bostrom, that the infection is conveyed to man from vegetable sources. Such a mode of infection cannot be considered as likely in either of our cases. One patient was a shipyard labourer; he had not handled grain or straw, nor worked at any time on a ship which had carried a grain cargo. The other was an assistant in a drapery shop, who had never lived outside Newcastle. The type of organism present in this latter case corresponds to that described by Wolff and Israel and by Homer Wright.<sup>1</sup> The recent observations by Colebrook<sup>2</sup> lend fresh support

to the work of Wolff and Israel. Colebrook points out that a truly anaerobic organism, such as is found in most cases of human actinomycosis, has not been recovered from any vegetable source, and in view of the slight viability of the human organism its survival upon vegetable matter is unlikely. He impregnated sterile oats with a fluid culture of the human organism and introduced it into the pleural and peritoneal cavities of rabbits; in no instance was actinomycotic infection established. He favours the view that so-called *Actinomyces bovis* is a frequent inhabitant of the alimentary tract of man, and may be carried into the tissues in certain unknown circumstances. He has isolated Gram-positive filaments resembling actinomycetes from carious teeth, and refers to similar observations from the investigation of these observations it would appear desirable to investigate systematically the bacterial flora of the mouth in cases of actinomycosis in any part of the body.

The pathway of entry of the organism also remains uncertain. Actinomycosis of the lung is a well recognized affection, and in the second of our cases infection could be explained by inhalation; in the first case, however, no pulmonary lesion at all was found at autopsy, and the disease remained throughout limited to the pleura and adjacent mediastinal tissues. Invasion from the skin is certainly not the explanation in this case, as the skin in the early stages was quite normal in appearance and free from movable over the underlying abscess. Inhalation into the main bronchi with infection of the mediastinal glands and subsequent lymphatic spread to the pleura is unlikely, as there was no trace of any lesion in the bronchi, and the only mediastinal gland involved was a small one on the side opposite to the pleural lesion. Finally, the possibility exists of infection by way of the oesophagus, a view put forward by Poncet and strongly supported by Cope.<sup>4</sup> In a considerable number of the reported thoracic cases pulmonary symptoms have been late in onset and have been preceded by the appearance of the lesion in the chest wall. The theory is that the mediastinum is infected from the oesophagus, and thence the disease spreads directly to the pleura, usually in the lower part of the chest. In these cases, therefore, extensive disease is usually to be found in the mediastinum, but this was not so in our first case, and it appears to us very doubtful if oesophageal infection can be held to account for the pleural lesion in this case. The suggestion, therefore, is that the pleura was infected by the blood stream from an unknown primary focus, probably in the mouth or other part of the alimentary canal.

We would refer the reader to a useful summary of the present evidence regarding the etiology of the disease by Warwick.<sup>5</sup>

#### TREATMENT.

Our experience of treatment in these two cases was that neither potassium iodide, vaccine, nor x rays was of any avail. In the case in which the disease was limited to the pleura and adjacent mediastinum it is possible that more radical surgical treatment, in combination with the other measures, might have been effective. In a remarkable case recorded by Bigland and Sergeant,<sup>6</sup> recovery followed the following treatment: (1) irrigation of the right pleura and pericardium with a solution containing collosol iodine; (2) potassium iodide, 25 grains three times daily by mouth, later changed to iodopin, 1 drachm three times daily; (3) collosol iodine intravenously. In another case of pulmonary actinomycosis recorded by Malcolm,<sup>7</sup> cure was obtained by incision, scraping and removal of ribs, potassium iodide by mouth, and finally vaccine treatment.

## TORSION OF THE GALL BLADDER.

BY

L. R. FIFIELD, F.R.C.S. Eng.,

SURGICAL FIRST ASSISTANT AND REGISTRAR, LONDON HOSPITAL.

TORSION of the gall bladder is a very rare condition, and in consequence I report the following case.

A married woman, aged 54, with six children, whilst taking tea on February 17th, was seized with severe pain in the right upper abdomen. She vomited frequently bright green bile, and the pain and vomiting continued until the morning of February 19th, when she was admitted to the London Hospital. She had not previously had similar pain, nor flatulent dyspepsia, jaundice, or any abdominal condition, although, until seven years ago, she was alleged to have suffered from periodic "bilious attacks," consisting of headache, slight sickness, but no pain, lasting for about a day. She was always constipated.

The temperature on admission was 99°, pulse 94, and respirations 24. The abdomen was slightly distended, and did not move well on respiration. Tenderness and rigidity of the right upper abdomen were pronounced, and a rounded lump, suggestive of a distended gall bladder, could be felt. Acute cholecystitis with a gall stone in Hartmann's pouch obstructing the cystic duct was the clinical diagnosis.

**Operation.**—A right upper rectus incision was made and the rectus muscle retracted outwards. As soon as the peritoneal cavity was opened some serous fluid escaped and a black distended gall bladder presented. It was about 3½ in. long, the shape of a thick sausage, with the concavity directed upwards and forwards. The peritoneum completely covered it and attached its proximal end to the liver by a mesentery, which also contained the cystic duct. A cystico-duodenal fold ran from the under surface of the proximal end (the cystic duct end) to the duodenum. The gall bladder had rotated once completely on the cystic duct from right to left. The gall bladder was extremely mobile, and its wall in the region of Hartmann's pouch so thickened as to suggest to the palpating fingers a stone therein. I removed the gall bladder and explored the biliary passages, but found nothing else abnormal.

The gall bladder contained blood mixed with a little bile, but no stones. The wall was greatly thickened by haemorrhage, especially at the proximal end, where it measured a quarter to a third of an inch. The patient made an uninterrupted recovery.

I am indebted to Sir Hugh Rigby for permission to publish this case.

## Relation of the Peritoneum to the Gall Bladder.

The gall bladder lies in a groove on the under surface of the liver between the right and quadrate lobes. Generally the postero-inferior surface and fundus are covered by peritoneum, and the antero-superior surface is attached to the liver by fibrous tissues. Sometimes the gall bladder is crossed by a bridge of liver tissue, and may even be entirely embedded. Rarely it is completely surrounded by peritoneum and attached to the liver by a mesentery. Lett quotes Brewer as finding this condition in 5 out of 100 dissections of the gall bladder and ducts, while Mr. A. J. Walton observed it in 7 of his cases at operation. Very rarely this mesentery does not extend beyond the proximal end ("neck") of the gall bladder, so that nearly the whole of the latter is entirely unconnected with the liver. In such cases the gall bladder is extraordinarily mobile and liable to torsion. It is suggested by Mr. Walton that a mesentery is more common in cases of virginal ptosis. Not infrequently, especially in cases of ptosis, a peritoneal fold passes from the inferior surface of the gall bladder to the colon or duodenum or both. It is known as the cystico-colic or duodenal fold, and is a continuation of the gastro-hepatic omentum. It was present in three of Brewer's five cases of gall bladders with mesenteries, and also in the case of torsion here recorded.

## Previous Cases of Torsion.

Wendel in 1838 described the case of a woman, aged 23, who had torsion of the gall bladder, in which there were stones, whilst other stones had escaped through a perforation and were lying free in the surrounding abscess cavity. The cystic duct had twisted many times, but there was no gangrene of the gall bladder, presumably on account of the many adhesions present.

In 1909 Lett recorded a case in which the patient, aged 72, was found to have her cystic duct twisted four half-turns, but there were no stones present. She died twelve hours after operation.

In the *Medical Annual* of 1913, in the section on volvulus of the gall bladder, Moynihan and Upcott quote Kubig, who in 1912 published his own case, found *post mortem*, and the records of three and Fischer. These four cases occurred in elderly women. The gall bladder had rotated once or twice completely from right to left, was kidney-shaped, full of blood, and its wall was greatly thickened. In one of the four gall stones were present.

Hansen's case in 1921 was that of a woman, aged 79, who had an hour-glass gall bladder; whilst in 1921 Irwin published the case of a woman, aged 34, who on operation was found to have a volvulus, there being one complete twist in the proximal part of the gall bladder itself and not the cystic duct. No stones were present and she recovered.

Jonas operated on a woman, aged 67, in 1923, and found two half-twists of the cystic duct and stones in the gall bladder. She recovered.

## Summary.

In all the recorded cases the patients were women and the majority of advanced age. In just over a quarter (3 out of 11) stones were present.

The physical signs and symptoms were practically the same in nearly every case: sudden onset of severe pain in the right upper abdomen, vomiting, slight abdominal distension, rigidity most marked in the right hypochondrium, and a tender lump in the position of the gall bladder. In no instance was a correct diagnosis made, the condition generally being considered acute cholecystitis with a stone obstructing the cystic duct.

Although in nearly all cases the gall bladder was strangulated and gangrene inevitable, apparently (for example, Wendel's case) it may obtain a sufficient blood supply through adhesions to prevent this.

## OTITIC INTRACRANIAL INFECTION.

BY

H. LAWSON WHALE, M.D., F.R.C.S.

SURGEON (EAR, NOSE, AND THROAT), LONDON TEMPERANCE HOSPITAL  
AND HAMSTEAD GENERAL HOSPITAL.

As a sequel to otorrhoea, with or without mastoid involvement, the presence of pus in the cerebro-spinal fluid is a condition from which recovery is unfortunately not so common as to be uninteresting; and when the surgeon is not only faced with obvious meningitis, but also, in obedience to strong indications of brain abscess, is obliged to explore cerebrum and cerebellum, the patient's prospects are certainly not improved.

Recently at a hospital of 120 beds (the London Temperance) I had simultaneously under my care two cases of this type; and each made a quite unexpected recovery. The following are brief reports.

## CASE I.

A girl, aged 17, had had a discharge from the right ear for two years. In August, 1924, a radical mastoid operation (right) was performed. A month later she complained of giddiness and intense frontal headache; right external strabismus was present, with spontaneous nystagmus of the first degree on deviation to the left; there was indefinite thickening over the right jugular vein, and oedema of both optic discs. At first rigors were present; later the temperature, pulse, and respirations fell to subnormal. Pus was found in the lumbar cerebro-spinal fluid.

**Operation.**—The dura mater was widely exposed, and found to be under slight tension; the wall of the lateral sinus was rough and unhealthy. The sinus was explored with a needle, but only normal blood was extracted. At a second operation, two days later, the dura was very tense and quite devoid of pulsation; first the cerebrum, and then the cerebellum, was explored for pus—without success.

**Post-operative History.**—Spasticity of the left psoas, adductors, and hamstrings supervened and persisted for a month, then gradually cleared. Hernia cerebri slowly subsided. The intense headache was controlled by heroic doses of morphine and heroin. The patient was discharged well.

## CASE II.

A girl, aged 3, in November, 1924, underwent myringotomy for right acute otitis media. In January, 1925, she was admitted to hospital suffering from right mastoiditis, and a cortical mastoid operation was performed. Two days later she was isolated for pertussis. Four days later still the head was retracted, and there were convulsions of the right limbs, with paresis of the right side of the face and complete paralysis of the left arm. Pus was found in the lumbar cerebro-spinal fluid.

**Operation.**—Chloroform was the only anaesthetic employed, ether being contraindicated on account of cough. The dura mater was widely exposed, and found under slight tension. The wall of the sigmoid sinus was healthy. At a second operation, two days later, the dura was very tense, there was no pulsation whatever. Both

the cerebrum and cerebellum were fruitlessly explored for pus. The child appeared to be moribund, and required only a very little anaesthetic.

*After-history.*—The hernia cerebri gradually subsided, and the patient made a complete and uninterrupted recovery.

I would emphasize the value of the two-stage operation. It often happens, as in these two cases, that while it is manifestly the surgeon's duty to open the cranium it is not so obvious what further steps should be taken. It may be necessary to drain the meninges, or turn clot out of the lateral sinns, or explore the brain. Therefore it is often wise, in the first instance, merely to expose the dura widely. This drains any local extradural abscess; the relief of tension helps the patient; and, since the dura is more resistant to infection than is bone, no harm has been done. If there is no clear indication to proceed further, the patient is returned to bed. Except in the rare cases in which the condition clears up, apparently as a result of the simple decompression, the second stage is undertaken one or two days later. By now there is usually more exact evidence of the lesion to be dealt with—both clinical evidence and evidence from the appearances of the exposed area. But by now, also, the patient is more ill, and would possibly not stand the prolonged operation of removing bone. This, however, has been obviated by anticipation, and the exploration of brain or sinns only occupies a few minutes.

## Memoranda :

### MEDICAL, SURGICAL, OBSTETRICAL.

#### PROLAPSE OF GUT DISTAL TO A COLOSTOMY.

In performing colostomy, after finding the sigmoid colon, the surgeon gently pulls down the loose bowel until the descending colon is nearly taut, so that any loose folds of sigmoid are not left just above the opening. The interest of the case here recorded lies in the fact that the sigmoid distal to the colostomy made in the recognized fashion prolapsed 9 inches.

W. M., male, aged 75 years, admitted to the Paddington Infirmary on January 26th, 1925, stated that colostomy had been performed twenty years previously for cancer of the bowel. There was a left iliac colostomy through which 9 inches of gut prolapsed. The abdomen was tender and rigid, but replacement of the prolapsed gut caused these signs to disappear. The patient suffered also from capillary bronchitis. Death occurred in fifteen hours.

#### Necropsy.

In addition to advanced bronchitis in both lungs, chronic interstitial nephritis and generalized arterio-sclerosis were present. The colostomy had been performed at the lower end of the descending colon. The gut for 16 inches distal to the opening was oedematous, congested, and dilated. The remainder of the large gut was contracted and empty. There was no sign of any malignant growth in the abdominal cavity, but there was well marked diverticulitis of the pelvic colon; some of the diverticula were minute, containing nothing but mucus, but one, resembling a normal appendix in size and length, contained a small amount of faecal matter. These observations were confirmed on microscopical examination. The appearance did not suggest that any portion of the gut had been removed at the previous operation.

We wish to express our thanks to Dr. Bendle, medical superintendent of the Paddington Infirmary, for permission to record this case.

It would appear that this case of diverticulitis of the colon had been regarded as an inoperable carcinoma. Retroperistalsis depends on a state of tension. Retroperistaltic waves once started may be augmented by an increase of internal pressure (Causton). The fact that at the necropsy all the large gut except the 16 inches distal to the colostomy was empty suggests that the tension of this part of the gut caused by the presence of faeces initiated a retroperistaltic wave, which was sufficiently strong to cause prolapse of a portion of mucosa, and that the lumen of the gut was thereby obstructed, causing a further rise in tension which led to a greater degree of prolapse. Such a complication is obviously prevented by the frequent periodic flushing out of the segment of the bowel distal to a colostomy opening.

London, W. F. J. S. HALL, M.B., M.R.C.S.

### TREATMENT OF DIABETES BY RAW FRESH GLAND (PANCREAS).

I DECIDED to try the treatment of diabetes by raw fresh gland in a lady of 67, who had been on a strict diet for six weeks without any appreciable improvement. The percentage of sugar present before gland treatment was 2.65; after four days' trial sugar had completely disappeared. I then recommended gland ingestion every other day for a week, when the urine showed a return of the glycosuria, but only 0.22 per cent. She returned to her original daily dose, when again, after a few days, the urine was free of sugar. She declares herself wonderfully better, her abnormal thirst and appetite having practically disappeared.

From experience I think it unsafe to be too dogmatic on any line of treatment for diabetes, as, despite recent research, the etiology and pathology of some cases are most puzzling and they refuse to respond to any form of treatment.

HELENA POMEROY KELLY, M.B., Ch.B.

Wolverhampton.

Mrs. K. aged 50, who had been treated for diabetes by dieting since January last, appeared from the history to have suffered from diabetes for at least two years. Under treatment some symptoms subsided, but the specific gravity of the urine was never reduced below 1030; it was usually considerably higher, and the percentage of sugar was only reduced to 2.5. The patient objected to trying insulin. Raw pancreas was started on March 17th (as recommended by Dr. Hollins, *BRITISH MEDICAL JOURNAL*, March 14th, p. 503), and on March 21st the urinary sugar was reduced and the specific gravity of the urine was 1025. By April 24th the urine was free of sugar and the specific gravity, 1020. The patient put on one pound in weight, and all symptoms disappeared. Apart from the addition of the pancreas, which was taken five days a week, no change was made in the diet.

Cardiff.

CONSTANCE L. GRIFFITHS.

### X RAYS IN THE TREATMENT OF WHOOPING-COUGH.

Dr. H. I. BOWDITCH, in the *Journal of the American Medical Association* (vol. i, 1924, p. 1422), gave an account of the treatment of 300 cases of whooping-cough by x rays at the Boston Floating Hospital. References to the work of Dr. Bowditch and his colleagues appeared in the *Epitome*, November 29th, 1924 (para. 424), and December 20th, 1924 (para. 491). A previous article on this subject was published by Dr. Bowditch in the *Boston Medical and Surgical Journal* of March 8th, 1923. Acting on the suggestion, but adopting a rather simpler technique, I have used the method in nine consecutive cases of whooping-cough during the past three months, and my experience may be summarized as follows.

1. The cases were all well established examples of uncomplicated whooping-cough, and four were very severe. The ages of the patients ranged from 1 year and 9 months to 55 years, and the duration of the attack from ten days to four months.

2. The dose of x rays varied with the age of the patient from 1/4 to 3/4 pastille dose, using in each case a suitable aluminium filter and a tube of equivalent spark-gap of 8 inches. In each case the dose was directed to the inter-scapular area from behind, this being the nearest point of approach to the root of the lungs, where enlargement of the lymphatic glands occurs in this disease. Two doses were given, with an interval of one week, in all except three cases, in which one dose only was given. The patients received no other treatment.

3. In all the nine cases so treated the cough ceased in less than a fortnight, and in no case did it recur; the cough at night was the first to be stopped.

The rationale of the method is explained by Dr. Bowditch, and I have personally confirmed the existence of enlarged glands at the root of the lungs. I do not believe that any bad sequelae are likely with these small doses, which have been employed in a large number of cases of early tuberculous adenitis; this invariably clears up under similar but

more prolonged treatment without unpleasant results. I venture to draw attention to the method in the hope that it may be more extensively practised in a disease in which other methods of treatment have been generally unsatisfactory. The relief which followed its use in these cases was extraordinary. If the good results are confirmed by more extensive trial we appear to have at our disposal a method of treating whooping-cough which will cut short its distressing symptoms, prevent the onset of many complications, and materially reduce its mortality.

Glastonbury, Somerset.

J. W. J. WILLCOX, M.B.Lond.

### POISONING BY EUCALYPTUS OIL.

The following case of poisoning by eucalyptus oil, in which alarming symptoms arose, may be of interest to readers. Other cases have been recorded in the *BRITISH MEDICAL JOURNAL* (1906, i, pp. 558, 1020, 1085).

A boy, aged 16, was recovering from measles when he was given by mistake half an ounce of eucalyptus oil. He swallowed the draught from the medicine glass without looking at it, and immediately said, "You have given me eucalyptus instead of my medicine." He felt some burning in the mouth and tried to cough the oil up, without success. In two or three minutes he suddenly became faint, and, according to the parents' account, was quite unconscious. On arrival ten minutes later I found the patient much collapsed, almost pulseless, and completely unconscious. The conjunctival reflex was nearly absent, and the breathing stertorous. With difficulty I got a little mustard and water down, but as there was no proper reflex action of swallowing I desisted. However, the boy vomited twice; whether this was due to the poison or the mustard I cannot say. His colour and pulse improved, but as I was not satisfied I washed out the stomach three or four times with the stomach tube. Three hours later the bowels acted involuntarily, but the patient remained comatose for another hour, when coughing commenced and the conjunctival reflex became brisk. Two hours later still, speech and recognition of relatives had returned, and the subsequent recovery was uneventful. The patient told me that he remembered nothing of what happened from the time of his feeling faint at 11 a.m. until about 5 p.m. On recovery of consciousness he complained only of thirst; there was no abdominal uneasiness. The symptoms therefore were those rather of a narcotic poison than of an irritant.

The poisonous nature of such a common household remedy is probably not widely known.

Horwich, near Bolton.

J. S. SEWELL, M.D.Ed.

### SACRALIZATION OF FIFTH LUMBAR VERTEBRA WITH PRESSURE ON LUMBAR PLEXUS.

The following case, of a condition which I believe to be rare, seems worthy of record. I am indebted to Mr. A. M. Sinclair, honorary surgeon to the Victoria Hospital, Burnley, for permission to publish these notes.

A man, aged 30, sustained an injury in March, 1924, to the lumbar region of the back. A week after the accident the patient was completely free from pain. On returning to light work, five weeks later, he noticed that his back was easily fatigued, and towards the end of April, 1924, he began to suffer pain in his back over the site of injury. He experienced increasing weakness in the right leg, and later on pain in it on exertion. About November, 1924, he found he could not completely extend his right knee, the attempt to do so causing pain in the back, shooting down to the right heel.

When examined in March, 1925, some flaccidity and wasting of the muscles of the right thigh and right calf (? due mainly to disuse) and considerable weakness of the right quadriceps femoris were present. There was limitation of all movements at the hip-joint, in particular of those of extension and internal rotation, and all movements at that joint caused pain over the right posterior superior iliac spine. The knee-joint could not be completely extended, and attempts to do so produced pain over the right posterior superior iliac spine, shooting down the back of the right leg to the heel. There was evidence of interference with sensory filaments in a slight loss of the sense of superficial touch, marked loss of pain sense over the anterior aspect of the right thigh extending upwards as far as Poupard's ligament, and also considerable loss of deep muscular sensibility in the right calf. No variation in the reflexes could be made out. The Wassermann reaction was negative.

The skiagram disclosed a shadow, suggesting bone in density, extending from the lower portion of the right transverse process of the fifth lumbar vertebra downwards to the first piece of the sacrum, and outwards, rather more vaguely, to the iliac crest a short distance above the posterior superior iliac spine. A homologous but rudimentary process was present on the left side.

In March, 1925, the patient was operated on at the Victoria Hospital, Burnley. On separating the muscles through a posterior incision a small bony process was found tapering downwards and outwards from the lower portion of the right transverse process of the fifth lumbar vertebra, and being prolonged as a band of firm fibrous tissue to the iliac crest. Below it was connected with the first piece of the sacrum. The fibrous band was cut, and the bone removed flush with the transverse process of the fourth lumbar vertebra.

After the pain immediately subsequent to the operation had subsided the patient found that he could completely extend his knee without pain. When the operation wound had healed, all movements at the hip-joint were found to be normal and painless, and also there was definite evidence of returning cutaneous sensibility. On April 18th the patient was discharged from hospital, all symptoms of the condition having disappeared.

R. B. HENDERSON,  
House-Surgeon, Victoria Hospital, Burnley.

### SECONDARY CARCINOMA TREATED WITH DEEP X RAYS.

ALTHOUGH the patient in the following case eventually died, the effect of deep x-ray therapy was in certain respects so favourable that it appears worth while to record the facts.

A lady, aged 48, in the spring of 1921 had a small nodule just above the clavicle on the right side. The left breast had been excised five years earlier for carcinoma. The right arm was slightly swollen. The patient was of a very nervous temperament, with dilatation of the left pupil and a suggestion of exophthalmos; the pulse rate was frequently accelerated, and her condition resembled in certain respects the thyroid type. By the autumn of the same year there was considerable glandular involvement in both supraclavicular regions, especially the left; the glands were very hard and adherent to the cervical tissues.

The surgeon who had operated in the first instance pronounced the condition inoperable, and she was transferred to Frankfurt, where she was placed in the City Hospital, under the care of Professor Schmieden. Though the condition was not considered suitable for irradiation, in view of the extent of the glandular involvement and the swelling and neuralgic pains down the arm, she received irradiation of three hours on each side of the chest on October 25th, 1921. First field (left breast and axilla): Distance 80 cm.; dose 100 per cent.; filter 0.5 mm. of zinc. Second field (right supraclavicular area from front): Distance 40 cm.; dose 100 per cent.; filter 0.5 mm. of zinc. Third field (right supraclavicular area from behind): Distance 40 cm.; dose 100 per cent.; filter 0.5 mm. of zinc.

Within a month from the date of treatment a distinct difference in the size of the glands was observable, an improvement that still held at the end of five months. Marked improvement was observed in the general health; the condition, however, could not be regarded as cured, pleuritic friction being audible between the shoulder blades. Blood examination showed: Haemoglobin 100 per cent.; red blood cells 7,400,000, white blood cells 10,600 per c.mm. Anaemia of the ordinary hyperplastic type was therefore present. X-ray examination gave no evidence of intrathoracic involvement.

She paid a second visit to Frankfurt on April 10th, 1922. For about six weeks prior to this visit the supraclavicular glands had shown a tendency to increase. Professor Schmieden found her general condition improved. X-ray examination of the thorax revealed a long narrow mediastinal band, but screening showed the retrocardiac space free. Several bronchial glands appeared enlarged, which may explain pains she experienced in the chest. The mediastinum, however, being free, was treated with high x-ray doses. The left thorax, axilla, and clavicular area were treated at 70 cm. and 80 cm. distance by two fields, giving 50 per cent. erythema skin dose each, the filter being 0.5 mm. of zinc, the milliamperage 3, the spark-gap 44 cm., and the time 115 minutes with each tube. This was immediately followed by a 70 per cent. dose at 50 cm. distance, given obliquely from the left scapula, the irradiation field being 10 by 15 cm. Five days afterwards the right clavicular region was also irradiated—moderated, owing to the state of the patient, to a 90 per cent. dose at 50 cm. distance with a field of 10 by 15 cm.

A third visit was paid in August, 1922. The left gland had markedly decreased and flattened out, the right glands had increased and even slightly involved the skin—a striking commentary upon the relative underdosage on the right side in April. The general condition of the patient was poor, although Dr. Hoffelder, who had charge of the patient while she was in Frankfurt, reported that she stood the journey fairly well. The percussion note was damped in the left posterior thorax, with pleuritic friction; there was pain, and a diagnosis of pleural metastases was made. The supraclavicular and infraclavicular regions were treated with 100 per cent. erythema skin dose at a distance of 80 cm. This was followed by almost immediate retrogression of the glands in the right supraclavicular area.

During the ensuing year the general condition sank. Constipation remained a marked feature; she became thinner. The blood sank to 55 per cent. of the colour index. The glands involved the skin above and below the clavicles. The pulse rate rose to 120 to 140. Arsenic and radium made little difference.

The facts of the case were of interest, notwithstanding the negative outcome. It was over seven years from the date of the primary operation that the patient succumbed, and, giving a year for the primary growth, the illness was of over eight years' duration, with a clear interval of five years. In October, 1921, she was so ill that x-ray treatment was almost refused. The opinion of the observers, both in London and on the Continent, was that the first and second irradiations exerted a definitely retarding effect on the growth of the cervical glands. The advantages of the treatment lay therein, in a partial relief of pain, and in the belief that everything possible was being done for her.

Glasgow.

ARTHUR TURNBULL.

FRIEZE IN FAÇADE OF PATHOLOGICO-SURGICAL SECTION OF THE POLICLINIC IN ROME; LISTER.

## LISTER, THE INVESTIGATOR AND SURGEON.

BY

SIR WILLIAM WATSON CHEYNE, Bt., F.R.C.S., F.R.S.

THE first Lister Memorial Lecture, established under the International Lister Memorial Fund, was delivered by Sir William Watson Cheyne, Bt., before the Royal College of Surgeons of England on May 14th. The full text, with an appendix, will shortly be published by Messrs. Longmans, Green and Co. In the course of his lecture Sir William Watson Cheyne said:

The story that I have to tell, though it goes back for just sixty years, is still full of vitality; it is a fascinating tale, far exceeding in interest the most exciting detective story ever written. And it is a true story. It is the story of a fight against a series of diseases—the infective or septic diseases of wounds. Until Lister's time any wound of the skin, whether the result of an accident or of an operation performed by the surgeon, involved a very great risk to the patient of serious illnesses. A surgical ward in a hospital was a place in which most of the patients were visibly ill, with flushed faces, parched lips, delirium, severe pain, etc., and many of them were evidently on the verge of death; the wards were pervaded with a peculiar mawkish odour which was very trying to newcomers. Lister's first introduction to septic diseases was when he became a dresser in the surgical wards at University College Hospital, London. I think that his very first case had been attacked by phagedenic gangrene, one of the most terrible of these septic diseases. That and other similar cases impressed him so greatly that he never forgot them, and always felt that no study was more urgent or might be more fruitful than the attempt to find out the cause.

When Lister became professor of surgery in Glasgow and was appointed one of the surgeons at the Glasgow Royal Infirmary, late in 1861, he had done excellent experimental work on the early stages of inflammation, coagulation of blood, etc.—work which was to be of the greatest value to him in future and for which he had been elected, at the early age of 33, a Fellow of the Royal Society. Lister made an extensive experiment in his wards with ordinary cleanliness, but without success, and one can imagine his depression when he found that the best methods he could think of did not help him at all, and that pyæmia and all the other septic troubles dogged his footsteps and rendered his best work nugatory.

But it so happened, though Lister did not then know it, that the cause of putrefaction was being revealed about the time that he was appointed professor of surgery in Glasgow. About 1860 Pasteur not only closed the proof against the spontaneous generation of yeast cells, but also opened up a new and extremely vital line of research by pointing out that other fermentations than the vinous, such as the butyric and the putrefactive, were also dependent on living organisms. Pasteur himself does not seem to have had at the time any idea of the importance of this part of his

investigations, and as far as I can ascertain only three men thoroughly realized it, or at any rate made any attempt to utilize the knowledge, within the next few years. These men were Jules Lemaire, Spencer Wells, and Joseph Lister.

Jules Lemaire was, I fancy, of the type of the delightful old learned family doctor. He had no surgical hospital appointment. He at once saw that Pasteur's statement was of great importance, and wrote on the bad effects which might arise from bacteria; he washed his wounds with various antiseptics, notably carbolic acid, with the view of hindering the growth of bacteria in the discharge, but never suggested, as Lister did, that these antiseptics should be used to kill the germs before they got a footing in the body or in the wound.

In 1864 Spencer Wells, one of the pioneers in ovariotomy, in an address at the meeting of the British Medical Association,\* gave a most excellent description of Pasteur's work and its bearing on surgery. He was a great practical surgeon and a bold operator, but, curiously enough, he did not follow up the logical conclusions he drew from Pasteur's works. Indeed, his only remark as to the practical application of the work was that "surgeons should always secure the most scrupulous cleanliness and purity of everything surrounding them"; as regards any other treatment, he advocated the internal administration of sulphites.

The third man, so far as I can find, who took up Pasteur's work was Joseph Lister. I understand that he was walking home with his colleague Professor Thomas Anderson, the professor of chemistry in Glasgow, one afternoon towards the end of 1864, discussing putrefaction and its causes, when the latter suggested that he should read certain papers on fermentation and spontaneous generation which had been recently published by a rising young French chemist, Louis Pasteur. Lister, who naturally was not conversant with chemical literature, at once got these papers, and from their perusal he found that it was not the gases of the air that the surgeon had to fear but minute living particles floating in the air and settling on surrounding objects in the form of dust, and that so long as these particles were excluded from the putrescible material after it had been boiled putrefaction did not occur. When the protection was removed and the dust was allowed free admission, minute bodies belonging to the lowest class of vegetable life could be seen swarming in the fluid, and putrefaction very quickly set in.

The conclusion was that some of the particles excluded by filtration or destroyed by heat were actually living germs, which, as they developed in the putrescible material, set up the putrefactive fermentation, just as the vinous fermentation was only set up on the admission of living yeast cells.

\* BRITISH MEDICAL JOURNAL, 1864, vol. ii, p. 381.

At that time, and until Lister left Edinburgh, the rivalry among the students—between Lister's followers and those who continued the old system—was very marked. The Listerians, who were considerably the more numerous, looked on the non-Listerians as lost souls, Tories of the most die-hard description, and not likely, when they came to practise their profession, to be able to give their patients the best chance possible. The non-Listerians, on the other hand, looked on the others as crazy believers in vain things like germs, rash to a degree, blinded with their enthusiasm, placing their patients in the greatest danger by the outrageous treatment that they proposed, and, as they said that their wounds did not suppurate while those of the other side did, liars of the first water. This rivalry increased for a considerable time, and when I became Lister's house-surgeon in Edinburgh, in 1876, it was probably at its height. It was, I believe, of the greatest value to the cause of asepsis. It made us all extremely careful, because we knew that everything we did was closely watched and no excuses would be accepted if a case went wrong; it would be the principle that would be blamed, and not the individual. By this time the antiseptic treatment had reached a stage where we felt that suppuration should not occur in an operation wound made through unbroken skin; if it did occur—and as we were not perfect, one or two cases would suppurate during the six months' session—we all felt it very much; we went about as if everything were lost, ashamed to raise our heads, and subjected to merciless chaff. Our only topic of conversation among ourselves on such occasions was how the infection had got in, what was the error in technique which had been committed, and whose fault it was. I do not hesitate to say that this holds true at the present time just as much as it did in the olden days.

By this time (1872 onwards) Lister's work had attracted more and more attention, and quite a number of surgeons began to visit Lister's wards. Curiously enough, very few British surgeons were to be seen, but other countries were well represented, especially Germany. Lister made a special point of showing all his methods and results to the visitors, and as there were constantly fresh arrivals he had to repeat his story frequently; thus his hospital visits were somewhat prolonged. In the early days to which I specially allude the steam spray had not yet been introduced, and it was very hard work to keep a hand spray going for any considerable time. The dressing of a patient followed a regular routine: the dresser on duty got on his knees at the side of the bed, and as soon as the bandages had been cut he started his hand spray; Lister then lifted off the outer dressing, which was solemnly handed round to each distinguished foreigner to smell. Having satisfied themselves that there was no putrefaction, the deeper piece of gauze which was generally placed over the region of the wound was passed round to show that there was no pus; in cases where it had not been possible to bring the edges of the wound completely together blood clot could be seen in places between the edges of the incision. In such cases Lister usually covered the wound with a piece of material called "protective," which was impermeable to carbolic acid; when this was exposed he would take a pair of forceps and peel it off, exposing the wound with the adherent organizing blood clot lying in the spaces where the edges had not come together, solid and firm, and with no sign of inflammation or suppuration in the wound. As a rule, this was followed by a sort of gasp of surprise by the distinguished foreigners, and then a violent conversation would break out among them, accompanied by equally violent gesticulations, so that one became alarmed lest the peace of the nations was going to be endangered. The poor dresser, who was almost, and indeed sometimes actually, faint from the pumping of the carbolic spray, was for the time being completely forgotten. But, however exhausted he was, and however much his wrist and arm ached, not one of his dressers would give in and let Lister down.

For some years Lister was probably most interested in revising the operative treatment of every disease or injury that presented itself from the point of view that he need not now fear sepsis in the operation wound. At first he did

more bone work than anything else—ununited fractures, badly united fractures, deformities of bone (he was the first to operate for knock-knee, very much on the lines of operation devised by Sir William MacEwen some time later), wiring or pegging recent fractures—for example, fractures of the patella or olecranon—operations for varicose veins, open radical cure of hernia, extensive operations for cancer of the breast, and so on.

He was the first to resuscitate suprapubic lithotomy, though this is generally attributed to others. His remarks on this matter will be found in my notebook, where his reasons for this suggestion are given, but he was not very happy in their practical application.

He continued his efforts to find fresh antiseptics which might be less irritating and more useful than those he had hitherto employed, and reconsidered the treatment of all sorts of cases which came before him from the point of view of whether something better might not be done for them by operation than was being done at that time on the knowledge that sepsis might be reckoned to have now been entirely abolished from wounds made by the surgeon through unbroken skin. It was probably in that direction more than in any other that Lister's work became so intensely interesting to the students. They would come to his wards and see treatment employed which had apparently never been heard of or thought of by the other surgeons who did not employ antiseptic measures. It would be hopeless to attempt to give any sort of list of the new operations which Lister did, and he himself absolutely declined to publish them.

When I became more intimately associated with Lister I made repeated requests to be allowed to publish notes of his clinic, especially of the new operations and new lines of treatment which he was employing; but although he had done that sort of thing for Mr. Syme, he pointed out, quite correctly, that the matter was very different, and that if such procedures as opening joints, complicated operations on bones, and many others, were published, it might quite well happen that some surgeon who was not a believer in antiseptic treatment, or not sufficiently acquainted with the technique, might perform an operation on similar lines, and being without the protection of antiseptics the patient might quite well lose his life or limb as a consequence. That is the explanation why so little is known of Lister as a surgeon. But, as I said, I think that it was his fresh outlook on treatment, and the interest of speculating what fresh procedure Lister would suggest in a particular case, that fascinated the students most. The only sphere of operative work in which he did very little was abdominal surgery. Indeed, with the exception of ovariectomy, which was curiously enough supposed to be a very difficult operation and one sacred to a few specially gifted men, comparatively little work had been done in abdominal surgery as we now know it before Lister retired from practice, and he openly stated that he did not feel justified in embarking on surgery in a region with which he was not thoroughly familiar.

I became Lister's house-surgeon in Edinburgh in October, 1876, having spent nearly a year in Vienna and Strasbourg. I found the greatest enthusiasm over Lister and his work. Indeed, the fact that I had worked in his wards and was going to be his house-surgeon on my return to Scotland was a sort of open sesame, and one of the professors actually asked me to show him exactly how Lister dealt with his cases.

It was in the spring of 1877 that Lister accepted an invitation to go to London as professor of clinical surgery at King's College, conjointly with Mr. John Wood. The first that I heard of it was one Sunday morning, I think a day or two after he received the invitation, when I was sleeping quietly in the house-surgeon's bedroom. I woke up to find someone shaking me, and to my astonishment on opening my eyes I found that it was Lister. He told me about his invitation to London. He had not yet at all made up his mind about it, but if he went he would need to take a small staff with him familiar with his methods, and he had come down that morning to know whether, if he decided to go, I would go with him and again act as his house-surgeon for six months at King's College Hospital. Go

with Lister to London! I could not believe my ears. Of course, I would go with him to London or anywhere else. In addition he took Dr. John Stewart (now one of the leading surgeons in Canada and held in very great esteem there), Dr. W. H. Dobie of Chester, and Dr. Altham (who died soon afterwards) as clerks.

He arranged to begin his work there at the beginning of the winter session in October, 1877, and he was asked to give the address at the opening of the winter session. At that time he had become very interested in the question whether there were different "species" of bacteria, each with its own actions on fermentescible substances or in connexion with diseases. He had already been working with milk, and he decided to investigate the lactic fermentation of milk, which he did during the summer and autumn of 1877. He satisfied himself by many ingenious experiments that a small bacillus, to which he gave the name of *Bacillus lactis*, was the only cause of the lactic fermentation of milk, and its sole external function in the scheme of nature. The research was carried out with the precision and thoroughness which characterized all Lister's work.

He not unnaturally thought that the absolute demonstration of a specific bacterium, explaining much that was obscure at that time, would be of the highest interest to his audience. Large numbers of the leading surgeons in London and the provinces came to hear this lecture. Perhaps not unnaturally they expected to be told about the revolution in surgery which Lister had inaugurated, and instead they had to sit for an hour listening to details of a series of experiments which proved that the lactic fermentation of milk was due to a particular bacterium. The expressions on the faces of the audience were very interesting and rather amusing; the majority of the surgeons present could not understand what the lactic fermentation of milk had to do with surgery. Those were the days of the "practical surgeon," as opposed to the "scientific surgeon," the latter being supposed (why I cannot imagine) to have no practical skill or knowledge. It took a considerable time before the "practical surgeon" realized that his day was past.

When we arrived in London, as far as I can remember no one at King's College was doing anything specially in the direction of antiseptic work, and indeed only a very few surgeons in London. As regards Lister's lectures, the chief thing that struck us at once was the almost entire want of enthusiasm among the students as compared with Edinburgh; there was no crowd running to get a good seat. Apart from Lister's dressers, only a few students would stroll into the theatre quite casually, apparently taking little interest in the lecture and seldom taking any notes. After the enormous classes in Edinburgh and their great enthusiasm it was very disappointing and depressing. We found after a time that probably the main cause of this was that the examiners in surgery for the various diplomas and degrees were for the most part not favourable to Lister's views, and the students were therefore afraid to attend Lister's lectures in case they should by accident give his views to the examiner. A good many of them, however, planned to stay in town for some time after they qualified so as to see something of Lister's work. This state of matters continued for some time but gradually died away.

Lister was quite well received by the staff and the students, but the nursing department was very difficult to work with. The hospital was at that time nursed by a sisterhood who looked on the wards as their private rooms, into which no man should come without their permission, nor should he interfere with any of their arrangements, such as ventilation, etc. They could always produce a rule of their sisterhood why we should not do this or the other thing which we considered essential for the success of our work. Had we not possessed a keen sense of humour (being more or less of Scottish descent) I do not know how we could have got through, but most of the restrictions were so childish and so evidently invented on the spur of the moment that we could not but laugh at them. I believe the real trouble was that till we appeared on the scene the nurses dressed the wounds, but when Lister arrived he

naturally would not allow them to meddle with the dressings; this solution did not occur to me for some considerable time.

The staff, on the other hand, were quite cordial and interested. Not long after we arrived one of the surgeons was going to amputate a limb, and he asked me to come and look after the antiseptic arrangements. His technique was pretty defective, and he did not seem able to visualize the germs which were ready to seize every opportunity of getting into the wound, so I accidentally from time to time squeezed a quantity of carbolic lotion over his hands, for which I was, of course, very apologetic. He did everything that I suggested till it came to tying the vessels, for which he used silk and left the ends long. I begged him repeatedly to cut them short, and told him that they would never separate if the wound remained aseptic; but he was adamant—he had never seen a case where the ligature could not be pulled out after a few days. The wound healed by first intention except where the bunch of ligatures was, and no suppuration occurred. Day after day I dressed the case for him and he pulled the threads without success. Gradually he began to think that I had told him the truth, and ultimately I got him to pull the threads as far down as he could and cut them off as high up as possible. This he did, and fortunately, as I had taken special pains to keep everything aseptic, no infection took place, and that end of the wound was healed in a few days and no further trouble resulted.

At the time of the migration to London we were still using carbolic gauze, carbolic spray, and carbolic lotions, and although thymol, eucalyptus, and various other antiseptics were tried during the next four or five years, no real progress was made in this respect till after the publication of Koch's work on antiseptics. After that Lister took up various mercurial preparations, and a variety of gauzes impregnated with preparations of mercury were employed, which had all to be discarded after a time on account of irritation of the skin. Ultimately Lister examined a double cyanide of mercury and zinc, and this, being insoluble in water, was found to be unirritating. But it was effective as an agent to inhibit the development of bacteria, though possibly not to destroy them. It was soluble in the mixture of serum and blood which came from the wound in sufficient amount to render it an unfit soil for the growth of bacteria. This we have used ever since with quite satisfactory results, and I believe that it just fills up the loophole which is left where dressings which are simply sterilized but do not contain any antiseptic are employed. Where a large amount of discharge is expected I generally reinforce the cyanide dressing by a mass of salicylic wool placed outside it. As to these gauzes and wool, it must be remembered that though they contain antiseptics they must be sterilized in the autoclave also, because the antiseptics are not volatile, so that bacteria which may lodge in the dressing are not acted on by the antiseptic. The diluted lotions of mercury bichloride (1 in 2,000 and 1 in 4,000) were also largely substituted for carbolic acid; the carbolic spray had been given up in 1887.

Lister's active work in surgery came to an end about 1893. The death of Lady Lister in the spring of that year, followed soon after by his retirement from the hospital on account of the age limit, changed entirely the current of his life. But by that time general septic diseases had become practically unknown in his practice in so far as operations through unbroken skin were concerned, and suppuration, even of the mildest type, was an occurrence of extreme rarity, and the possibility of septic complications was quite negligible. He had also reached a point in his technique where the possible irritation caused by the antiseptics employed was not noticeable and did not interfere at all with the healing of the wounds.

In 1895 Lister was elected President of the Royal Society, and the work connected with that society gave him another five years of life. But after that, although honours continued to be showered on him, the great brain gradually became tired, his memory failed, and he began to long for the time to come when, as he firmly believed, he would meet his wife and his friends again and commence a new life.

## Reports of Societies.

### ABDOMINAL EMERGENCIES IN CHILDREN.

At a meeting of the Brighton and Sussex Medical-Chirurgical Society on May 7th, Dr. E. F. MAYNARD, the President, in the chair, Mr. M. FITZMAURICE-KELLY read a paper on some abdominal emergencies in children.

The mortality associated with these conditions was, he said, to a great degree preventable, and improvement in results was to be looked for mainly in the direction of earlier diagnosis and treatment. Dealing first with appendicitis, attention was called to the fact that, early in the attack, pain was often not localized, but was felt across the abdomen. The importance of a band of hyperaesthesia above Poupart's ligament, as evidence that perforation had not yet taken place, and the information to be derived from rectal examination, were especially emphasized. Treatment consisted in immediate operation, delay being dangerous in young children. The right paramedian incision with internal displacement of the rectus was preferred in most cases; in those with definite localization to the right iliac fossa Mr. Fitzmaurice-Kelly preferred Battle's incision, closing it again with drainage of the rectus sheath, and providing stab drainage elsewhere if necessary. In each individual case it had to be decided whether the peritonemum was capable of dealing with the exudate, but as a general rule drainage was more frequently required in diffuse peritonitis in children than in adults. The value of pituitary extract and eserine, in combination, in post-operative ileus was mentioned; in the worst cases jejunostomy was the only hope, and should not be unduly delayed. Acute inflammation of Meckel's diverticulum was briefly mentioned, and the value of a paramedian incision in dealing with it pointed out. Pneumococcal peritonitis was not very rare among young girls of the poorer class; many cases were mistaken for appendicitis; suggestive evidence was the onset with symptoms of pelvic irritation—loose stools, painful and frequent micturition—and in acute cases severe toxæmia, with disproportionate increase of the respiration rate. The acute cases did best with drainage, and the value of blood transfusion, as recommended by Fraser and McCartney, was mentioned. Referring to intussusception, Mr. Fitzmaurice-Kelly laid stress on the extreme gravity of the condition, and the serious mortality—about 30 per cent.—associated with it. This was almost entirely due to a failure to recognize the urgency of the case at the outset. The clinical picture was very definite and strikingly uniform, and it was a serious error to delay treatment because a tumour could not be felt or no blood was passed when the symptoms were otherwise suggestive. Three recent fatal cases were detailed, illustrating the sources and the dangers of delay. Pyloric stenosis in infants was, in the light of recent improvements in technique, claimed as a surgical emergency. The early diagnosis, and especially the differentiation of stenosis from pyloro-spasm, were discussed, and Rammstedt's operation was described. In view of the fact that the mortality of cases operated on by this method was of the order of 30 per cent., against 80 per cent. in those treated medically, Mr. Fitzmaurice-Kelly contended that an operation should be performed at the earliest possible moment after the diagnosis was definitely established.

Mr. L. A. PARRY recalled a case of intussusception in which pain had been absent throughout, and the symptoms were otherwise obscure. He did not find cutaneous hyperaesthesia of much value in practice, and regarded the physical signs of rigidity and tenderness on pressure as of more value than symptoms. He called attention to the difficulty of diagnosis between appendicitis and certain cases of ileo-caecal tuberculosis, and was strongly in favour of immediate operation in appendicitis in children.

Mr. H. NETHERSOLE FLETCHER remarked on the virulence of cases of appendicitis starting with diarrhoea. In the matter of drainage he thought no risk should be taken, and in cases of doubt a tube should be left in. He discussed the diagnosis of intussusception from gastro-intestinal catarrh with bloody stools in infants, and noted particularly the intermittency of the symptoms in the former.

Mr. J. R. GRIFFITH advocated a transverse incision outside the linea semilunaris, splitting the rectus sheath if more room were required, in cases of acute appendicitis. The President and Mr. H. M. GALT also took part in the discussion.

Mr. FITZMAURICE-KELLY, in reply, agreed with the President that the diagnosis of appendicitis had not grown more exact, but contended that, in the presence of acute symptoms, an early exploration was the safest course, and the attempt to arrive at certitude might lead to a fatal delay. The same argument applied with even greater force to intussusception, and he had never seen any harm come of a negative exploration.

### DIAGNOSIS AND TREATMENT OF INTRA-THORACIC DISEASE.

A MEETING of the Manchester Medical Society was held on May 6th, the President, Professor G. R. MURRAY, being in the chair.

Mr. H. MORRISTON DAVIES read a paper on observations on the diagnosis and the treatment of intrathoracic disease. In the first part of the lecture five cases of particular interest, as regards either diagnosis or treatment, were described. The first was a case of gumma of the lung simulating tuberculosis. The second was a case of primary bronchial carcinoma, which was discovered accidentally by the x rays in a patient suffering from chronic bronchitis and emphysema. The diagnosis was made originally on the radiogram, then made more certain by the appearance of characteristic symptoms, and finally confirmed by operation. The third case was that of a woman who for thirty years had attended hospitals for dyspepsia, dyspnoea, and tachycardia; the x rays revealed a diaphragmatic hernia. The fourth case was a unilateral bronchiectasis, due, it was discovered as a result of treatment, to fragments of teeth which must have been in the lung for ten years. The bronchiectasis was treated by artificial pneumothorax and phrenicotomy; following collapse of the lung, fragments of tooth were expelled. Later, owing to the lung creeping out, the symptoms returned and a thoracoplasty was performed. Following this a still larger fragment of tooth was coughed up, since when the patient had remained perfectly well. The last case was of a man wounded in the neck by shrapnel which caused mediastinal suppuration and chronic pneumonia, the consequence of which was bronchiectasis with offensive sputum. The shrapnel in the base of the lung escaped notice until an x-ray photograph was taken with very oblique rays (from above downwards). Phrenic evulsion was done, paralysing that dome of the diaphragm, since when there had been disappearance of all symptoms. The second part of the lecture was devoted to a description of the value of phrenic evulsion and thoracoplasty. Phrenic evulsion had superseded phrenicotomy because it broke the continuity of the accessory phrenic as well as the phrenic itself. It was therefore much more effectual, and almost constantly resulted in paralysis of one half of the diaphragm, the dome on that side rising up into the thorax and producing partial collapse of the base of the lung. The operation was of value for basal tuberculous and bronchiectatic lesions of the lung, for abolition of diaphragmatic cough, for relief from

with coughing, as an aid in cases of as a means of reduction of the pleural cavity in cases of chronic effusion, as a preliminary to thoracoplasty, and as a means of testing the resisting capacity of the opposite lung. It was also a prophylactic measure against onset of bronchiectasis in cases of unresolved pneumonia. The statistical results of thoracoplasty were practically the same as those for pneumothorax—namely, 35 per cent. healed, 30 per cent. improved, 35 per cent. unimproved or worse. The operative mortality was about 8.5 per cent. It was indicated in unilateral, or mainly unilateral, cases of tuberculosis in which there were extensive mechanical changes, and in which artificial pneumothorax was impossible owing to adhesions, also in unilateral bronchiectasis. Slides were shown illustrating the collapse of the lung and chest wall, and the comparatively slight and resultant outward deformity.

## ANEURYSM.

A MEETING of the Section of Medicine of the Royal Academy of Medicine in Ireland was held on May 1st, the President, Dr. F. C. PURSER, in the chair.

Dr. J. SPEARES read a paper on aneurysm, based on his examination of 607 cases in the cardiac clinic of the Ministry of Pensions; in 37 cases a diagnosis of aneurysm was made. An aneurysm was present in one patient, aged 30. In 13 cases the Wassermann reaction was positive and in 17 cases negative. In 10 cases the diagnosis depended entirely on the x rays, and in no case was a tracheal tug present. Dr. Speares attributed the large number of aneurysms in his series to the fact that an x-ray examination was made as a routine in all cases.

The PRESIDENT referred to the difference between the blood pressure in the two arms as a very important diagnostic point; it would be interesting, he said, to determine whether this difference occurred only when the aneurysm was in one place, or when the aneurysm was in the ascending aorta or elsewhere. He had never seen a case in which stimulation of the sympathetic from an aneurysm had occurred.

Dr. H. C. DRURY commented on the small number of cases of aneurysm found in patients under 30 years of age, and asked if these cases were marked out as being syphilitic. He had almost always been unable to detect tracheal tugging. A change in their voice was often the first thing noticed by these patients, and Dr. Drury thought that in a great many cases this was a very good indication as to what was wrong. For some time now the difficulty of diagnosing the presence of aneurysm, without an x-ray examination, had been recognized. The lack of pain in these cases was one of the great difficulties regarding diagnosis. At present he had a patient in hospital, an elderly woman, with no symptoms at all except some indefinite pain in the chest, but an x-ray examination showed an undoubted aneurysm.

Dr. T. G. MOOREHEAD commented on the fact that while 37 cases of aneurysm were encountered out of the 600 cases that were examined in Dublin, only 6 cases of aneurysm were found amongst the 300 similar cases examined in Glasgow. His own experience was that radiologists differed enormously in their diagnosis of aneurysms. In his experience, nearly every patient with a genuine aneurysm had a positive Wassermann reaction also.

Dr. A. R. PARSONS had been able, by means of x rays, to find aneurysms in patients which would probably never have been detected without x-ray examination.

Dr. V. M. SINCE thought that swellings of the aorta fell into three classes: (1) The cases in which the lumen of the aorta was a little larger than usual but there were no pressure symptoms; there was usually a systolic aortic murmur and an accentuated second sound. These cases should not, he thought, be classed as aneurysms. (2) The typical cases of sacular aneurysm, due to syphilis; he had never come across one in which the Wassermann reaction had been negative. (3) Cases with a general dilatation of the aorta, occurring in old people with marked arterio-sclerosis, associated with some pressure symptoms, such as dysphagia, and with a negative Wassermann reaction. He agreed that tracheal tugging did not often occur, but at present he was treating a case in which it was exceedingly well marked, and it could be both seen and felt.

Dr. W. G. HARVEY said that there was a great difference in the width of the aorta in different people, and the width of the aorta measurement was no criterion of an aneurysm at all. The diagnosis was made almost entirely on the screen, and not from the photograph. A dilated aortic arch had occasionally been taken for an aneurysm by radiographers. He did not think that it was for want of a uniform plan of examination that mistakes were made, for nearly every radiographer adopted the same plan.

Dr. SPEARES, replying, said that in five or six cases they had been put on the track of an aneurysm simply by noticing the difference in blood pressure in the arms. Every patient had been examined by x rays, some twice. No mention had been made of any cases except those reported as definite aneurysms. Each man had been examined

eight, and sometimes ten, times for tracheal tugging, and this condition had never been found. They had never been able to satisfy themselves that in any of the cases there was any reasonable evidence of diastolic shock, and he would put this condition in almost the same class as tracheal tugging. Two of the patients with aneurysm, under 30, had syphilis, but the others had not. As a result of his experiments, he had not any doubt that x rays were the most reliable means at present available for diagnosing aneurysm. He thought it quite possible that there were cases of what might be called border-line aneurysms, but these were very few. They were indebted to their radiologist for detecting aneurysms in some cases when they had been doubtful about it, and also for finding aneurysms in cases in which previously they had not been suspected.

## Reviews.

## FRACTURES AND DISLOCATIONS.

THE new book on *Fractures and Dislocations*<sup>1</sup> by Dr. PHILIP D. WILSON of Harvard and Mr. WILLIAM A. COCHRANE of Edinburgh is an important one, for it embodies the experience and the opinions, not only of the authors whose names appear upon its title-page, but those of a large number of American surgeons skilled in the treatment of these injuries. Primarily it is the expression of the views of the members of the fracture service of the Massachusetts General Hospital in Boston, which service grew out of the fracture squad organized by that well known authority Dr. C. L. Seudder. This service has been at work since 1920. It is responsible for the treatment of all cases of fracture and dislocation admitted to the wards or cared for in the out-patient department of the hospital. It is composed of six surgeons, two being appointed from each of the two surgical services and two from the orthopaedic service. The results of this innovation have been most satisfactory. In 1922 the staff had arrived at practical unanimity concerning methods of treatment, and in the same year a conference of surgeons of wide experience in the States and Canada agreed with the service as to the main conclusions now set forth in this book. As the authors remark, "It was perhaps surprising and certainly gratifying to find such an unanimity of authoritative opinion."

Very rightly the authors have had an eye, in writing this book, to the needs of the general practitioner, and it will, we think, be found that the appliances required are such as are within the reach of most up-to-date medical men. The authors have set before them as their main object the attainment of a good functional result, which, as Mr. Dowden of Edinburgh has elsewhere shown, is not incompatible with considerable anatomical deformity. The chapter on the principles of treatment is valuable. The authors clearly state the paradoxical situation which faces the surgeon, who must choose between complete immobilization and its attendant risk of muscular atrophy and malnutrition of the limb, and incomplete immobilization with risk of imperfect alignment. The principles and means of treatment are well and clearly set forth; among the latter the Thomas splint occupies a prominent place. As regards the use of plaster-of-Paris, the authors are in agreement with Sir Robert Jones in recommending that encircling plaster should not be used unless it is divided along at least one side. For compound fractures débridement is recommended as much in peace as in war, when the soft parts are extensively damaged, and the Carrel-Dakin system is advocated in infected cases.

In sixteen chapters the injuries of various regions of the body are described, each chapter beginning with well illustrated statements of the normal anatomy, followed by descriptions of the methods of treatment which have been found to give the greatest satisfaction. The chapters on fractures of the femur and leg bones are very full, as befits these important

<sup>1</sup> *Fractures and Dislocations*, by Philip D. Wilson, F.A.C.S., and William A. Cochrane, M.D. J. B. Lippincott Company, 1924. (Med. 8vo, pp. xv + 789; 978 figures, 65s. net.)

general recommended, and direct skeletal traction by ice-tongs is favoured, especially for fractures of the femur. These chapters represent a complete survey of the subject of the book, and even include fracture of a sesamoid bone of the great toe. The illustrations are many and good.

We can safely recommend this book as one of the best and most up-to-date guides for the general practitioner, as well as for the expert surgeon and the student. It well fulfils the promise of its title-page to deal with the immediate management, after-care, and convalescent treatment, with special reference to the conservation and restoration of function.

### TUMOURS AND CANCER.

MORE than sixty years ago Virchow stated his belief that no man then living could say what precisely constituted a tumour. In a recently published monograph on present knowledge of tumours with special reference to the carcinoma,<sup>2</sup> Professor CARL STERNBERG of Vienna expresses the opinion that Virchow's dictum still holds good. He reviews the subject from several aspects and in the light of an extensive literature. The literature, it is true, is mainly German, but this limitation is here not altogether a disadvantage, since it serves to bring out the fact that the conclusions of German writers are practically identical with those reached by authorities in other countries.

Several authors are quoted to show how varied are the attempts at a satisfactory definition of a tumour, the nearest approach being that it is a new growth increasing autonomously, independently of other structures and without a functional objective. The benign and malignant tumours are best differentiated by the degree of maturity or completed growth, the former being mature, the latter immature growths. A clear line of demarcation, however, is not anatomically possible, for benign tumours, which histologically have many malignant characteristics, are not uncommon. Several investigators have endeavoured to determine the malignancy of a tumour by the morphological, chemical, or functional characters of its cells, but none of the explanations are adequate. Professor Sternberg expresses special interest in the Freund-Kaminer reaction of the serum of cancer-free individuals on cancer cells, but he points out that, though this may be of value in diagnosing cancer, it does not demonstrate any actual difference between the chemical characters of malignant and of normal tissue cells. Similarly no clear differentiation is possible from a consideration of such functions as secretion, phagocytosis, motility, and liability to degenerative or other changes. We are warned, therefore, against diagnosing malignancy by the character of individual cells.

Professor Sternberg also agrees with Virchow in considering that neither chemistry nor physiology affords a basis for the classification and nomenclature of tumours. Their classification must be anatomical. The nomenclature, however, has become confused by the introduction of new names ending in "oma," such as cerebroma, nephroma, hepatoma, and so on. In a chapter on metastases and recurrence, the impossibility of setting a term to the period within which the latter may occur is emphasized. Cases are quoted of tumours recurring thirty years after operation.

The etiology of tumours and the experimental researches on animals are considered. The author points out that the many theories of the causes of cancer all come within the range of Virchow's cell irritation theory, Cohnheim's embryological theory, or the parasitic theory. None are held to be altogether satisfactory, although they go a long way and add to our knowledge. Experimentally the most acceptable theory of causation is held to be that, as indicated by the tar-cancer experiments on mice, under the influence of some excitant, pathological regeneration is induced, which will develop into a tumour, will continue to grow independently and may become malignant, if the irritant acts long enough and often enough on cells predisposed to excessive pathological regeneration. In this

sense any mechanical, chemical, thermal, or parasitic irritant might become the causative agent of cancer. Although this theory enables us to understand many of the facts in the pathology of new growths, Professor Sternberg considers that we are far from a definite solution of the problems involved.

The concluding chapter of his book deals with the vexed questions of heredity, transformation of benign into malignant tumours, formation of new growths on cicatricial tissue, spontaneous disappearance of tumours, coexistence of cancer and tubercle, cancer and gastric ulcer, cancer and gall stones, and the influence of pregnancy. Statistics are regarded as untrustworthy, especially in connexion with the increase of cancer generally or in some countries more than in others. The only statistics regarded as approaching reliability tend, it is said, to show that no general increase in cancer is taking place, and that differences in its incidence in one country and in another are probably due to the personal equation of the observers and to different methods in diagnosing and recording the cases.

### X-RAY THERAPY.

*The Principles and Practice of Roentgen Therapy*,<sup>2</sup> by Dr. I. SETH HIRSCH of New York, is a book which is the direct outcome of the later developments of x-ray therapy due to the introduction of the high voltage transformers and the use of a well filtered stream of highly penetrating x rays. As the author points out, the striking development of this technique is that it has placed x-ray therapy on a scientific basis, and that it now rests firmly upon the foundations of physics, chemistry, and biology. That the final word has not yet been written is obvious, but present-day procedures are far removed from the somewhat haphazard and go-as-you-please methods of the earlier days—methods, however, which in many hands often gave surprisingly good results: it should be remembered that the more scientific use of the small repeated x-ray dose now possible plays an important part in rational x-ray therapy. It is neither necessary, nor, indeed, indicated, that every case suitable for x-ray treatment, even cases of malignant disease, should be treated by the so-called method of "deep therapy."

The book under review is divided into three parts. The first, in which the illustrations are numerous and valuable, deals with the apparatus which is required, and consists of ten chapters. Of these the first section deals with high potential generators, the second with high tension voltage measurement, the third with x-ray tubes, and the fourth with installations. As regards tubes the author states definitely that the "electron" is the most practicable for therapeutic purposes. It is interesting to note Dr. Hirsch's statement that with respect to the protection of the operator, the patient, and those adjacent to the apparatus, nothing better can be written than the report of the X-ray and Radium Protection Committee of Great Britain.

The second part of the book contains two sections, of which the first is devoted to the question of the measurement of the quality of the radiations, and the second to the measurement of their intensity. All the different methods are explained and come under critical review. Many illustrations and tables are of great assistance in making the letterpress quite clear. The third part has four sections. Dosage, practical and theoretical, accounts for the first two; in the third the clinical aspect is dealt with; and the last, after an introductory chapter, contains particulars of the dosage formulae and tables of Dr. HOLZKNECHT, the professor of roentgenology at Vienna.

It will be seen that this book is not based upon a narrative of various cases treated by x rays in which the methods of treatment and the results obtained are related, but is a clear and scientific study of the methods of production of x rays, the apparatus used, and the principles upon which modern methods are based and carried out.

Well and clearly written, beautifully illustrated, exceed-

<sup>3</sup> *The Principles and Practice of Roentgen Therapy*. By I. Seit Hirsch, M.D. With Dosage Formulae and Dosage Table by Guido Holzknecht, M.D. New York: American X-Ray Publishing Company; London: H. K. Lewis and Co., Ltd. 1925. (Cr. 4to, pp. xviii + 359; 300 figures, 57 tables. £3 net.)

ingly well presented, it is a standard work on the subject which will become indispensable to any radiologist who is practising x-ray therapy.

### EDUCATIONAL PSYCHOLOGY.

THE interest displayed in psychology by teachers of the young has both advantages and disadvantages. So far as it enables them to understand their charges, to enter into their minds, and recall something of their own memory of the processes of mentality at an early age, the study of psychology is all to advantage. But if it should lead them to explore the more remote and devious passages mapped out by some of the more revolutionary of modern psychologists it is doubtful if it will be to the advantage of either the teachers or their charges. Some of the ramifications of modern psychology are calculated to have unhappy effects upon the minds of youthful teachers, and the majority of teachers are young. Youthful minds are very open to suggestion, and the ultra-sexual bias of some psychologists is likely to have effects upon these young minds which may bring about the very conclusions of these theorists. With such fears in mind it is not easy to recommend a useful work on psychology as a suitable guide to study for young educationists. It is therefore with pleasure that we read the volume written by Dr. GODFREY H. THOMSON, entitled *Instinct, Intelligence, and Character*.<sup>1</sup> Dr. Thomson is professor of education at the Armstrong College, Newcastle-upon-Tyne, and a year ago became visiting professor of education in Columbia University, New York. The lectures delivered there have become the basis of the book now under review.

It is a thoroughly good book, the product of a well read, thoughtful, and well balanced mind; the author knows so clearly what he wishes to say that he says it simply and forcefully. His general plan has been to show how man's mind has grown out of the animal mind. Out of instinctive behaviour grows the beginning of reason, as the reactions grow less inevitable. Evolution creates out of this an animal which replaces some of the behaviour by substitutes which save time. Imagery, and then symbols unlike the actual behaviour, come to replace it still more subtly; words bring with them the dangers of parrot-learning as well as the powers of abstract thought. The educational implications of this way of thinking are that we should recognize the trial and error aspect of creative thought, and provide for the increasing abstraction in the materials. We should provide opportunities for problems to arise, encourage the widest variations in the solutions offered, and should insist on ruthless rejections after trial.

This is a dry summary of a most interesting thesis, but it is a fair indication of the trend of the best thought in education, one that provides for the natural elasticity of fresh minds.

### ESSENTIALS OF INFANT FEEDING.

THE highest commendation can be given to a little book entitled *Essentials of Infant Feeding*<sup>2</sup> by Dr. E. A. BARTON, medical officer to the Child Welfare Department, University College. He modestly claims in the preface that the book is no more "than a collection of those facts which it is essential that a student should know if he is to profit by attendance on a hospital infant clinic." It is at the present time compulsory for students to have some slight knowledge of the manner of life of infants. Very few students there are, however, who are sufficiently philosophical to take the long view expressed in the adage "Prevention is better than cure." The operating theatre would be crowded when a Caesarean section is performed, but a very small percentage of these students is found to attend the infant clinic in order to observe the regulation of a normal infant's life. Yet, how many Caesarean sections is the average practitioner called upon to perform compared with the number

of healthy or mildly ailing babies for whom his advice will be asked? Possibly the blame for this lack of interest in the normal infant lies at the door of the infant dietitians, whose dogmata and formulae have become so complicated and so unpractical, not only for the student's memory, but for the mother's.

Hence it is that such a book as this will be heartily welcomed, read, and digested by practitioners and students alike. It is a clear, explanatory survey of the present teaching on the subject. There is an entire absence of dogmatic statements, and there is no particular reference to the various schools of teaching on infant feeding.

Fortunately, in the present decade, it is more readily recognized that the feeding of infants is important, and the practitioner who advises a mother "to put it on milk and water," without giving exact quantities, modifications, and times of feeding, is becoming more and more rare. Nevertheless, those doctors who have acquired such accurate and detailed knowledge as is necessary for dealing with infants have won their experience only at the cost of considerable effort, and much expenditure of time and patience.

In this little book of 80 pages will be found every fact of importance in infant feeding. The condensation of the subject-matter into paragraphs with clear headings makes for easy reading and rapid reference. We confidently recommend this excellent book to every practitioner and student.

### LABORATORY DIAGNOSIS.

VOLUME XXVII<sup>3</sup> of the French series of books on medical pathology and applied therapeutics is written by Professor. PRUVOST, with an introduction by Professor LERULE, and deals with common laboratory methods employed in the diagnosis of disease. With the multiplication of biochemical, bacteriological, and histological tests the subject of laboratory diagnosis has grown to be a separate branch of pathology, or, more exactly, a stout limb of the tree of pathological knowledge which is continually budding fresh branches. The practising physician, looking to the laboratory for help in the diagnosis of disease, often needs counsel in the interpretation of the pathologists' reports; or he may wish to know what particular tests are likely to be of service in a particular case. The authors of this book have written with these thoughts before them, but, carried away with their subject, have produced a book which, as it stands, is more likely to be of value to the laboratory worker himself than to the clinician. Its pages are closely packed with detail of technical tests, the descriptions gaining an added value from the intensive fund of practical experience on which the authors call. They have lauded their subject in a sensible fashion, distinguishing between specific and non-specific methods of analysis. Non-specific tests only reveal lesions or disordered functions of organs; examinations of blood, urine, and sputum are commonly non-specific tests. Specific tests are such as disclose the actual nature of the disease or its etiology—for example, the search for pathogenic bacteria or protozoa. Working on this plan the book has been divided into two parts: in the first are described tests which are useful in the examination of gastric secretion, sputum, cerebro-spinal fluid, pus, blood, faeces, and urine; in the second the authors deal in alphabetical order with the army of bacteria, protozoa, and worms which attack mankind. The book is liberally illustrated with 168 figures and 12 coloured plates.

The little book by Dr. J. A. KOLMER and Dr. F. BOERNER ou *Laboratory Diagnostic Methods*<sup>4</sup> is a successor to the popular *Manual on Clinical Pathology* by Pepper and Klaer, which apparently is no longer obtainable. Drs. Kolmer and Boerner have adopted the style of their predecessors and written a book which describes the technique of various laboratory tests without any discussion of their value,

limitation, or clinical applications in the diagnosis and treatment of disease. It has no illustrations. Every alternate page is blank, presumably so that the student may fill in notes on the tests mentioned or add others found serviceable. No doubt this will be a useful guide to the students who work under the direction of the authors, but it is not the sort of book for a beginner who is not receiving guidance from an experienced pathologist. The four sections into which the book is divided deal successively with clinical, pathological, bacteriological, serological, and blood chemistry methods. Usually only one method of performing a particular test is given, and not infrequently that one method does not happen to be the favourite in this country; for instance, Jensen's modification of Gram's stain, Leishman's stain, and Maclean's methods for blood sugar estimation are not mentioned.

### FRENCH MEDICAL YEARBOOKS.

There is a pathetic interest in the fifth issue of the *Année Thérapeutique* (1924).<sup>4</sup> On November 14th its author, Dr. CHEINISSE, left the unfinished preface on his desk, and within three hours met with an accident which ended his life. His son has published the work as it then stood, though two or three chapters had not been finally revised. The book is divided into two sections, both arranged alphabetically; the first deals with diseases and symptoms, the second with technical methods. It is a summary of work in the treatment of disease recorded in many countries. The striking feature in all these records is the use of the syringe, a practice which must be even more prevalent abroad than in the home of vaccine therapy. Thus, there are descriptions of intrahepatic injections of emetine for amoebic abscess of the liver; injections of insulin and glucose for pre- and post-operative acidosis; intra-articular injections of sodium iodide for syphilitic arthropathies; intrajugular injections for inefficiency of the right ventricle; and intraumbilical injections of adrenaline for asphyxia neonatorum, and injections of water into the umbilical cord for retained placenta. In the technical section Dr. Cheinisse called attention to the report of a committee of the American Medical Association on the dangers of local anaesthesia. Though there is a natural disinclination to publish cases of mishap, the committee collected forty-three cases of death following local anaesthesia, and found that in many of them the supposed diagnosis of status lymphaticus was not supported by facts. The ex-anguination-transfusion experiments and practice of Bruce Robertson are described in their application to the toxæmia of extensive burns, to erysipelas of the newly born, to acute intestinal intoxication, malignant scarlet fever, and septicaemia. Dr. Cheinisse mentions very few English writers, but alludes to a warning to surgeons by Sir James Mackenzie that they may not have sufficient knowledge of angina pectoris to justify them in resecting the depressor nerve or the sympathetic for the treatment of this disease.

The *Précis de Thérapeutique*,<sup>5</sup> the latest number of the French series *Bibliothèque du Doctorat en Médecine*, has been compiled by Professor PAUL CARNOT and Drs. F. RATHERY and P. HARVIER. It is based on the lectures delivered by Dr. Carnot, professor of therapeutics in the University of Paris, and covers the course prescribed by the university syllabus. It is divided into three sections, the first of which deals with prescription writing and tabulates the principal remedies used in medicine and the manner in which they may be administered; it closes with some general remarks on doses and incompatibilities. The authors deal next with general therapeutics, classify available medicinal substances into different groups according to their manner of action, and in each group discuss the value and method

of employment of each substance in various diseases. The second section of the book, which occupies much less space, concerns itself with dietetic treatment of diseases such as diabetes, gout, and rheumatism. The third section, which deals with glandular treatment, is included in the last seventy pages. This book, written by experienced teachers in the University of Paris, is likely to be valuable to the French medical student.

The fourth issue of *L'Année médicale pratique*,<sup>10</sup> edited by Dr. CAMILLE LIAN, supported by a staff of thirty-three contributors, contains in alphabetical form a concise account of the principal contributions to medical literature in the widest sense of the term during the past year. A new feature of the present issue is a review of Swiss publications by a committee composed of Professor Roch of Geneva and his two assistants. We learn that similar committees are being formed in Belgium, Canada, the Argentine, and Brazil for the review of the literature of these countries in the next issue.

### NOTES ON BOOKS.

In his little book entitled *Resistance to Disease*<sup>11</sup> Dr. HARRY MERRALL maintains that the mucous membrane of the nasopharynx constitutes the first line of defence against disease, the second and third being formed by the lymphoid tissue lower down in the alimentary canal and the thyroid gland respectively. He regards adenoids merely as an expression of the overwork of the defensive organs in the nasopharynx, and urges that in operations for enlarged tonsils and adenoids the affected portion only of the glands should be removed. Restoration of a healthy condition of the naso-pharyngeal mucosa—which, according to the author, can best be effected by local applications of iodine—constitutes the most effective means of preventing recurrent colds as well as more serious affections, especially intestinal toxæmia and constitutional disorders, including cancer.

Professor OGDEN has produced a book on *Hearing*<sup>12</sup> which he hopes will be helpful to the teacher, the musician, the linguist, and the medical practitioner, especially if the latter be an otologist. It will, however, probably appeal still more to the psychologist and physiologist. The author begins by discussing the physics of sound, the physiology and the psychology of hearing, and the appreciation of music and language from every point of view; he returns to different aspects of these matters in later chapters in a manner which is rather bewildering. The main theme is the psychology of hearing, and the author has gathered together a vast amount of information hitherto scattered in articles and monographs; he has provided also an excellent bibliography. It is unfortunate that only too often the pleonasm and truism beloved of the psychologist obscure the meaning, which can only be dimly discerned in a cloud of verbiage. Thus the difficulties of a subject in itself complicated and frequently lacking precision are intensified. The accounts of the anatomy of the ear and of the theories of hearing are not complete; the author is more informing when discussing the sensation of tone and its various attributes. A chapter is devoted to vocabularies. The exact meaning of this term is not made clear, but it appears here to be applied to any vocal sound. The best part of the book is that which deals with the principles and teaching of music; here there is much of value about speech and music in education and tests of musical talent. The writer seems more in his own province on these topics. The scope of the book is wide, and perhaps too much has been attempted, but it improves vastly as it goes on.

The National League for Health, Maternity, and Child Welfare has issued a pamphlet containing outline syllabuses of *Health Talks*<sup>13</sup> to mothers. Drawn up by Miss MIRIAM SHEWELL, superintendent of an infant welfare centre in Birmingham, after years of experience in giving talks to mothers, she has condensed her informal lectures into the

<sup>4</sup> *L'Année Thérapeutique: Médications et Procédés Nouveaux*. Par le Dr. E. Cheinisse. Cinquième année, 1924. Paris: Masson et Cie. 1925. (54 x 73, pp. 185. Fr. 8.)

<sup>13</sup> *Health Talks*. By Miss Miriam Shewell. London: The National League for Health, Maternity, and Child Welfare. 1925. (Demy 8vo, pp. 16. 6d.)

outlines found in this book. The talks are divided into three series of twelve. The first series is for young married women and expectant mothers, and deals with the growth of the foetus and ante-natal care generally; the second is for mothers with young children, and details the daily routine with hints on food and clothing, on habits and on character building. The final series is limited to mothers who have attended the first two courses, as it deals with the causation, prevention, and nursing of simple diseases in children. Each syllabus has headings, which, although very brief, are quite sufficiently explanatory. The Ministry of Health requires all health visitors to give periodic talks to mothers, and this pamphlet supplies a working basis for such talks.

## MEDICAL AND SURGICAL APPLIANCES.

### *Automatic Skin Forceps.*

MR. E. DRYBROUGH-SMITH, F.R.C.S. Edin. (St. Leonards-on-Sea), writes: With ordinary skin forceps much time is wasted in approximating and everting the edges when suturing wounds, especially when operating without an assistant. The forceps depicted are designed to save time, and permit the surgeon to use both his hands to thread the needle, and pass and tie the suture when operating without an assistant. They are made of rustless steel and have a strong spring which firmly approximates the blades—thus the skin edges are automatically held tightly together; the teeth are long and firmly grip into the skin, at the same time everting its edges. In applying the forceps both edges of the skin are gripped simultaneously, the needle is passed just distal to the ends of the blades, and the suture tied before removing the forceps. Messrs. Down Bros., Ltd., 21 and 23, St. Thomas's Street, S.E.1, have kindly undertaken to make the forceps.

## THE UNITED STATES ARMY MEDICAL REPORT.

THE annual report of the Surgeon-General of the United States Army for the year 1924<sup>1</sup> maintains its reputation for carefully collected facts and lucid explanation of its statistical data. The vital statistics are for the calendar year 1923, but the general remarks cover the activities of the medical department for the fiscal year ending June 30th, 1924. In his letter of transmission to the Secretary of War the Surgeon-General, Major-General M. W. Ireland, refers specially to the important developments which have taken place in the formation of a reserve corps of medical officers, in enrolling and training the medical personnel of the National Guard, and in the training of the officers and men of the regular Army Medical Corps.

The medical department of the United States Army differs from that of the British Army in that it includes the veterinary as well as the dental and nursing services. The new reserve corps is intended to provide reserves, in the event of the mobilization of the man-power of the nation, for all these services from civilian sources. Up to June 30th, 1924, 7,559 were enrolled for medical, 3,055 for dental, 865 for veterinary, 880 for administrative, and 416 for sanitary services; 40,636 Red Cross nurses formed a reserve for the Army Nursing Corps. The National Guard resources are distinct from this reserve, and for federal purposes is able to put in the field 166 medical detachments (regimental), 10 medical regiments, 10 collecting (bearer) companies, 32 ambulance companies, 24 hospital companies, 10 medical laboratory sections, 10 veterinary companies, and 10 service companies, with a personnel of 950 officers and 8,459 men. An interesting table on page 177 of the report gives a statement of the organized reserve units required in the event of general mobilization. The number is 917, of which 270 are general and 180 stationary hospitals. To man them 23,563 reserve officers are required; but only 3,840 have as yet been definitely assigned to units, of which there are twenty-six different classes, all of them for rearward or lines of communication and base services. They include, for example, such units as "consultants at large," "specialist groups," aviation

medical laboratories, and medical supply depots. So far a complete personnel has been assigned to 3 stationary hospitals, 1 veterinary convalescent hospital, and 2 corps medical headquarters only. Many of the civil institutions throughout the country have undertaken to supply several of the units, 65 as surgical hospitals, 66 as evacuation hospitals, 126 as general hospitals, 1 as a stationary hospital, 1 as a general medical laboratory, and 1 as a veterinary general hospital.

These figures are of interest for comparison with the organized medical reserves of our own army. They are not, however, the equivalent of our Territorial Army Medical Service, which is represented more by the National Guard services of the United States; but of organized civil medical resources outside it. They represent a wide and far-seeing view of national requirements which we might do well to imitate if that were possible. It is only in our Voluntary Aid Detachment organization that we approach it.

The regular army medical officers were 46 below strength, being 939 of an authorized establishment of 985 for a mean annual strength of 130,827, exclusive of nurses and pensioners, who also come under the care of the regular Army Medical Corps. The officers of the Dental Corps numbered 155. Both medical and dental officers are considered totally insufficient in number. Only 62.8 per cent. of the medical officers were available for duty at general hospitals, camps, and laboratories, and only 71 per cent. of the dentists. The allowance of dentists is in the proportion of 1 for every 1,000 of army strength, but this proportion was determined nearly a quarter of a century ago, when the relation of dentistry to the general health was little known. The report states that at least twice the existing proportion is an urgent necessity.

General Ireland notes with satisfaction the great advance that was made during the year by the establishment in September, 1923, of an "Army Medical Center" in 110 acres of land about five miles north of Washington. This centre comprises the "Walter Reed" General Hospital, the Army Medical School, the Army School of Nursing, the Army Veterinary School, and the Army Dental School. A School of Aviation Medicine, it may be noted, also exists; it was established in New York in 1921.

The report enters into full details of the courses of instruction in the various schools and training camps for regular, National Guard, and reserve corps. Among the methods employed are medical correspondence courses for the officers of the reserve corps—a method which is at present occupying the attention of writers in the *Journal of the Royal Army Medical Corps*. The courses cover about 200 hours of work each, and deal with regimental duties, military organization, tactics, hospitalization, sanitation, first aid, military law, and other subjects. Tests and problems are sent out to the officers concerned, who in their turn submit their solution of them to the corps area instructor. An advanced correspondence course of thirty-nine hours' work deals with special subjects for reserve officers of the higher grades.

As regards the vital statistics, there is not much of special interest. Officers and men of all grades and colours seem to be wonderfully healthy, whether serving in the United States, the Philippines, Hawaii, Panama, or China. The only remarkable feature is the extent of invaliding on account of nervous diseases; 40.9 per cent. of the officers and men discharged on account of medical unfitness were invalided on account of these, while suicide was the cause of 9 per cent. of the deaths. A large proportion of the deaths—17.7 per cent.—was due to automobile, motor-cycle, aeroplane, and balloon accidents, or to drowning. The admission rate for venereal disease was comparatively low—60 per 1,000 of strength; it is the lowest rate for any of the previous ten years. Prophylactic packets are issued and prophylactic stations maintained in many of the garrisons, if not in all. The admissions for alcoholism, on the other hand, although lower than in 1922, were higher than in any other year of the decade. The report states that this was probably due to the injurious character of the illicit liquor consumed in recent years. Admissions for drug addiction were higher than in 1922, but compared favourably with other years.

<sup>1</sup> Annual Report of the Surgeon-General U.S. Army, 1924. Washington: Government Printing Office, 1924. (350 pp. xiv + 425; 165 tables in text, 5 statistical tables, and 25 figures. Price 60 cents in Washington.)

SATURDAY, MAY 16TH, 1925.

## THE TREATMENT OF FRACTURES.

MANY lives and limbs were needlessly sacrificed in the earlier part of the late war, before the treatment of gunshot fractures was reformed, and the mortality of cases of fractured femur—to take only one class of injury—was reduced from 80 to 20 per cent. The knowledge of the good results obtained in the special surgical hospitals led many of us to hope that the lessons taught by Sir Robert Jones, Major Menrice Sinclair, Sir Henry Gray, and others would not be wasted, but would be applied effectively by those responsible for the treatment of injuries in civil life. This hope was expressed during the last year of the war by Mr. Muirhead Little in a presidential address to the members of the British Orthopaedic Association,<sup>1</sup> in which he called attention to the defects of the then existing system, and pointed out that it was possible under it for the pupils of some metropolitan schools of medicine to become qualified to practise without having had any practical instruction in the treatment of some of the most disabling injuries to which the human frame is liable. He expressed the view that the treatment of fractures should be transferred from the general surgeons, who had neither time nor inclination to carry it out properly, to the orthopaedic departments of the hospitals. Unfortunately, as the lecture delivered by Sir Robert Jones on May 12th (published at page 909) will show, the hopes entertained nearly seven years ago were doomed to disappointment. The lecturer, who has had unrivalled opportunities of knowing the present state of things, tells us that “the majority of fractures treated by conservative or non-operative methods are badly handled, with resultant disability, and expert operative aid, if desired, is not always at hand.” He describes in graphic terms the usual course of events in the treatment of a fracture in the casualty department of a great general hospital and in the wards of those institutions which consent, more or less reluctantly, to admit fracture cases as in-patients. Few, we believe, will be found to deny the general accuracy of this description, or to assert that the present state of things is one with which we ought to be satisfied. It was a realization of the poor functional results obtained in treating fractures among the industrial classes that led some enterprising surgeons to advocate open operation and metallic fixation in simple fractures. These procedures have great value in certain cases, but in most cases better results can be attained without them, and they have the grave drawback of being generally inapplicable except in very well equipped hospitals.

The proper treatment of fractures with a view to the attainment of the best possible functional results needs much more time and attention to the details of after-treatment than can be given in most general hospitals as at present organized. The abdominal surgeon—and most surgeons to general hospitals must be so classed—accustomed to discharge his cases after two or three weeks or even less, does not want to have his beds occupied by cases in which the process

of recovery is inevitably prolonged, and his time is so fully taken up that he could not spare enough of it for the treatment of difficult cases of fracture, even if he had additional beds. Yet there is generally no skilled and experienced junior officer to whom he could delegate the work with confidence.

Sir Robert Jones, well knowing that it is useless to denounce a wrong without at the same time pointing out a remedy, has made very definite recommendations for reform. They are, perhaps, rather drastic, but may be taken as suggesting the ideal at which we should aim. The years since 1918 have not been wasted in all countries. In the United States, where industrial and transport injuries are so numerous, the treatment of fractures has been more specialized than it has been in Europe, and with excellent results.

We review in this issue (p. 928) an important book on dislocations and fractures by Dr. Wilson of Boston (Massachusetts) and Mr. Cochrane of Edinburgh, in the preface to which there is an instructive account of the special department of the Massachusetts General Hospital devoted to the treatment of fractures. This fracture service, as it is called, is staffed by six surgeons, of whom four are drawn from the two ordinary surgical services and two from the orthopaedic department. Since 1920, when this service was established, it has worked with complete harmony and success, and a remarkable consensus of opinion has been reached on the principles of practice. What is possible in New England might at least be attempted in Great Britain, and we trust that the appeal made by Sir Robert Jones will be answered in a practical manner, with the result that much suffering, crippling deformity, and economic waste will be avoided.

A century ago Sir Astley Cooper, who was one of the foremost surgeons in the world, did not disdain to devote much of his ability and experience to the treatment of fractures and dislocations. It will not be very creditable to his countrymen of to-day if they do not seriously set to work to restore the practice of this branch of surgery in Great Britain to the same relatively high position as that in which he left it.

## MEDICAL EDUCATION: TWO LAY VIEWS.

WITHIN the last few months two books by Americans of great ability have been published, each of which is mainly devoted to problems of medical education. One is a novel, Mr. Sinclair Lewis's *Martin Arrowsmith*,<sup>1</sup> the other a systematic treatise by Mr. Abraham Flexner.<sup>2</sup> Both authors are educated laymen, but their equipments for the task are different. Mr. Flexner has been for many years in close touch with the organization of medical research and education, and has had a large personal share in important developments of both. Mr. Sinclair Lewis is a man of letters who, until he conceived the idea of writing this tale, perhaps had no more intimate knowledge of medical education and research than any other cultivated man. Mr. Flexner's conclusions, then, are the product of many years' study, but, as a necessary defect of the quality, coloured by the fact that he has been an actor in as well as a spectator of the events he describes. Mr. Lewis's conclusions are based upon an experience much shorter and much less intimate, but more intensely realized, and, being expressed in terms of human personality by a skillful artist, far more vividly presented than those of Mr. Flexner. It would be strange indeed if two authors

<sup>1</sup> BRITISH MEDICAL JOURNAL, November 30th, 1918, p. 604.

<sup>2</sup> Published by Jonathan Cares, Ltd. 7s. 6d. net.  
<sup>3</sup> Medical Education: A Comparative Study. New York: Macmillan Company. 1925. (Pr. 33s. 2.50 dollars.)

so differently equipped reached identical conclusions; yet upon a number of important points they do reach the same conclusions; we shall be mainly concerned with these. Mr. Lewis has written the *Odyssey* of a lad endowed with intellectual ability and imagination who passes from the office of a drunken general practitioner to the medical faculty of a university, then, through general practice and the municipal public health service, into an institute of medical research. We leave him, if not among "barren crags," at least in the wilderness.

We shall not dwell upon the merits of Mr. Lewis's book as a piece of literary art, but one merit must be noticed because it is relevant to our limited argument. He sustains the thesis that the American medical student is, culturally, a mere barbarian, and that his professional training is machine-made and uninspired by any disinterested ideals; he further maintains that the organization of research in America is deeply tinged with a commercialism that puts power into the hands of persons as incapable of appreciating the spirit of disinterested research as is a deaf-mute of apprehending a sonata. Mr. H. G. Wells's most acrid humours never distilled such an acid as has eaten out the portraits of Dean Silva of Winnemac University, of Dr. De Witt Tubbs, director of the McGurk Institute, and of the director's favourite colleague Dr. Rippleton Holabird. But Mr. Lewis is a more accomplished artist than Mr. Wells because he can both see and dramatize the strong points of the men he satirizes. Dean Silva and Dr. Tubbs cut poor figures in comparison with the noble old Gottlieb as witnesses of scientific truth; they are mere wordy quacks. But in the sick-room it is not Gottlieb, but Silva, who is, and is made to appear as, the strong man. As director of a research institute Gottlieb fails, and fails miserably, in the very matters wherein he might have been expected to be Dr. Tubbs's superior; under Gottlieb there is not less, but much more, vulgar intrigue than under Tubbs; Tubbs, with all his intellectual dishonesty and desire for "stunts," is a better director than Gottlieb.

With Mr. Lewis's indictment of commercialized research we shall not deal, but that it is not wholly unsupported by the writer whose knowledge of organized research is unrivalled the following sentences from Mr. Flexner will show: "The speed and ease with which, in favoured spots, a complete and brilliant material transformation has been effected in the United States is not, perhaps, wholly without danger. Kraepelin has suggested that, up to a certain point, equipment improves efficiency; beyond, increase of equipment may be at the expense of the higher efficiency. . . . Mediocrity, to be candid, is more dependent than genius." Passing, then, to the other counts, both Mr. Lewis and Mr. Flexner agree that the American medical student is poorly educated. Mr. Flexner extends the same criticism to England. He finds that, while on the continent of Europe the medical student has "received a severe and excellent general education"—that he is "respectably educated in the technical sense of the term"—"in Great Britain and America no such selection has been made and no such intellectual training has been generally procured, though the medical student may be a more wholesome human being." As an indication he points to the very low standard of attainment in the use of their native tongue reached by American medical students, and even by many of their teachers—a criticism which, as most readers and all editors of medical journals know, is applicable, though with perhaps less force,

on this side of the Atlantic. Although, from the use of the word "selection" in the extract we have cited, it is evident that Mr. Flexner does not ignore all factors other than the national educational system, we think he may overrate the importance of the differences of system between the countries compared. We do not know whether it is still true that the proportion of qualified medical men per 1,000 of population is higher in England, and very much higher in America, than in France or Germany; but, even if it is not, there are social and historical reasons why the attraction of the medical profession for those who have undergone a really severe intellectual training—have been liberally educated, in the ordinary loose sense of the word—should be greater on the Continent than in the English-speaking countries.

Passing to the content and method of medical education itself, Mr. Flexner sometimes uses language as vivacious as that of Mr. Lewis satirizing Winnemac. Mr. Flexner, not Mr. Lewis, writes of the "inferior student, who had by main force to be held with his nose to the grindstone and in whose interest the American curriculum was invented." In his judgement of European systems, Mr. Flexner ranges us in a different order from that he found appropriate for pre-professional training. While, with some minor limitations, he ranked France first in the production of generally educated youths, he regards her medical schools as the least efficient of any—much inferior to the English and the better American schools. The French, in fact, are the worst, as we are the best, exponents of the "natural" system of training; a system which its admirers would describe as the practical method, the method emphasizing the fact that medicine is an art as well as a science, which its critics deride as the method adopted by Mr. Wackford Squeers—"C-l-e-a-n, clean, verb active, to make bright, to scour. W-i-n, win, d-e-r, der, winder, a casement. When the boy knows this out of the book, he goes and does it." To imitate an epigram of Matthew Arnold, Mr. Flexner's view is that the German medical school has plenty of science but too little art, the French school so little science that the art is not learned, the English school too little science but very admirable art.

It is not very easy to cite a representative passage, for Mr. Flexner is a cautious writer and not always self-consistent, but perhaps the following is typical: "The merits of the British system are great and obvious. They are fully appreciated by the British themselves and not unappreciated in other countries. In effect, the British student learns clinical medicine as an intelligent apprentice—an apprentice, I mean, who, in virtue of previous training, is soon capable of orderly procedure in the analysis of symptoms, the arrangement of data, and the drawing of tentative conclusions. Aside from the inadequate time usually given by the English chief to his teaching and the excessive responsibility laid upon the juniors, the educational defect lies, not in the system as such, but in the spirit in which it continues to be administered—namely, its short-sighted practicality. It is, indeed, as I have previously noted, remarkable how little British physiology has yet achieved in changing the spirit of British medicine. Annually, for years, a group, well trained in physiology at Cambridge, Oxford, and University College, London, enter the hospital schools and with rare exceptions soon settle down to clinical study at a level much below the level of their physiological training. They are, indeed, lost in the

mass of students with inferior preparation in whom they are merged. Listening to a succession of bedside expositions, not infrequently quite chatty in substance and tone, one is struck by the positive note; this, that, or the other indication is pointed out—rarely is the unknown, the problematic, the profounder question, the historic background alluded to. . . . As contrasted with the infinite complexities of the actual process, whether of health or disease, bedside teaching of this type enormously over-simplifies. It hardly penetrates the surface, and is apparently unaware of the fundamental activities involved in the phenomena of life." We have quoted this passage at length because it brings out very clearly both the weak points and the strong points of Mr. Flexner's criticism. The strong point is that too little provision is made in England for the minority, the small minority, of undergraduate students who have been liberally educated and could profit by the type of instruction given by a professor of the German model. The weak point is that in teaching adolescents who have undergone but little serious intellectual discipline—and that is the lot of nine clinicians out of ten—the instructor who ceases to be chatty and positive, who does advert to the historic background, the infinite complexities, of Mr. Flexner's peroration, will harm both his listeners and himself. They will snatch at ignorance-concealing phrases, he will degenerate into an orator.

There is surely one weakness of the present generation which a radical change of system along the lines which Mr. Flexner seems to advocate might accentuate. It is a slovenly omniscience, a lack of courage to confess that one is too ignorant of a subject even to criticize it. The old surgeon who, seeing his medical colleague enter the wards, turned to his dressers and said, "Thank God, gentlemen, I know nothing of medicine," has few successors. Mr. Flexner does realize this, for he has written another passage which seems to us the truest and finest in his book: "The remedy is to do less for the student rather than to do more for him. But when the curriculum has been simplified, defects and disappointments will not disappear; these, due largely to human frailty, cannot be exorcised by jugglery. Far more wholesome would it be to admit once for all the difficulty of learning medicine, and the impossibility of teaching it." That passage should be learned by heart by all students, teachers, organizers, patrons, and after-dinner orators. That Hippocrates made a similar remark some time ago does not detract from its immediate practical importance.

#### JOHN KEATS, MEDICAL STUDENT.

THE medical career of John Keats has been the subject of many writings, but Sir William Hale-White, in the Annual Oration before the Medical Society of London on May 11th, disclosed a few facts not generally known, the result of his own researches. The house of Mr. Thomas Hammond, the surgeon of Edmonton, to whom Keats was apprenticed, is still standing (No. 7, Church Street), and has still a doctor for its tenant. Close at hand is a tiny cottage, about to be demolished, in which Keats and a fellow apprentice lived. At the end of four years' apprenticeship—that is, midsummer, 1815—Keats entered himself as a student at Guy's Hospital, with which St. Thomas's, then just across the way, was associated. Some scoundrel, said the orator, had cut out from the register at Guy's, in which all students signed their names, the signature of Keats, evidently erasing the autograph; but two other books in possession of the hospital mentioned the poet, one of them in an entry as follows: "October 1st, 1815. John Keats, No. 57,

six months, place of education, Mr. Thomas Hammond, Edmonton, fee, £1 2s.," while the other recorded the fact that he had become a dresser to Mr. Lucas. Sir William Hale-White had studied the student's notebook of Keats, which is in the possession of the Hampstead Public Library, and had been permitted to make a photographic copy of each of its twenty-eight pages. On each left-hand page were notes on descriptive anatomy, well written and spaced, evidently set down at leisure, while each right-hand page was filled with closely written, hurried memoranda, many of the words misspelt or abbreviated—the notes of a student taking down a lecture. The notes of eleven lectures on physiology appeared in this fashion. A careful study showed that both the leisurely and the hurried notes were in the same handwriting, and a comparison with the letters of Keats proved that the handwriting was that of the author of *Endymion*. In one place some flowers were scrawled on the margin of the lecture note, as though Keats's attention had wandered from the theatre to those "realms of gold" of which he had already written. Keats had said once how during a lecture a sunbeam came into the room, and "with it a whole troop of creatures floating in the ray; and I was off with them to Oberon and fairyland." Sir William Hale-White read a number of passages from these old notes. There were many references—six in the anatomical part and fourteen in the physiological—to "Mr. C.": "Mr. C., by an experiment on a dog, showed that arterial and venous blood had the same temperature"; "Mr. C.'s opinion is that it (blood) is prevented from coagulating in the body by nervous energy"; "the lowest pulse Mr. C. . . . had ever heard of was in general 20, sometimes 28, at others as low as 14"; "Mr. C. had seen a dissection of the nerves in a man who had *tic doloieux*." Strangely enough, there were four men at that time lecturing at Guy's whose names began with "C," but a process of elimination showed that Keats's lecturer must have been Astley Cooper, and this was clinched by a reference to Cooper's lectures, published in 1824, many of the points and illustrations in which coincided with the rough notes taken by Keats in the lecture theatre in 1815-16. It is rather unfair to judge the merits of a lecture from a student's notebook, but Sir William Hale-White said that even on this test it was evident that the lectures were very good indeed, the facts well and clearly put, and the teaching extremely practical. He went on to give some account of the curriculum undertaken by the students attached to Guy's and St. Thomas's in the early years of the last century, the almost incredible rough-and-tumble of the operating theatre, and the personalities of the various physicians and surgeons, of whom Astley Cooper had by far the largest following. He thought it greatly to Astley Cooper's credit that, busy and popular man as he was, he noticed "little Keats," who was not his own dresser, and placed him under the special care of George Cooper, a relative of his. Keats lodged close to the hospital, for part of the time in a house in Dean Street, a street now cut through by the railway, though a portion of it remains under the name of Stainer Street. Here, among the "jumbled heap of murky dwellings," Keats wrote some of his poetry, he saw visions of Arcady in Southwark, and from his favourite window-seat coined that imperishable line, "A thing of beauty is a joy for ever." Keats never practised medicine, though in his letters there are many allusions to the possibility of his doing so; but he obtained the licence of the Apothecaries' Society of London, presenting himself for examination on July 25th, 1816, and passing with credit. Sir William Hale-White was fortunate enough to discover in the *London Medical Repository* of about that date a list of certified apothecaries who had just received their passes, and among them was the name of John Keats of Edmonton. But there were two persons in the

body of Keats—one of them the diligent student, sufficiently outstanding to attract the attention of Sir Astley Cooper, and popular among his fellow students, by whom he was known as "little Keats," and the other the poet; and the poet gained the day. Keats threw aside the lancet for what he called "the living pleasures of the bard."

#### THE COMMON GROUND OF LAW AND MEDICINE.

LORD JUSTICE ATKIN was the speaker at the annual meeting—the 151st—of the Middlesex Hospital Medical Society on May 12th, and explored what he called "the dusty purloins of a lawyer's mind" on the subject of law and medicine. Touching lightly on the history of the two professions, he remarked on the early embodiment of sanitary measures in legal codes, and said that perhaps the most powerful legislators of history had been Moses, Mahomet (both of whom were sanitarians), and the chief medical officer of the Ministry of Health. The professions had proceeded together, but not always at the same pace. While it might be said that the law had exhibited a fairly constant development from later Roman times, medicine had stood still for many centuries after Galen, and, indeed, until about fifty years ago medicine remained more or less an empirical art based upon incomplete experience and upon hypotheses which were to a large extent untrue. In recent times medicine had made enormous advances and had become a science, which could hardly yet be said of law, for law was subject to variation at the instance of legislatures as well as to the fallible interpretations of judges. Medicine and law were working towards the analogous goals of health and justice, which had much in common. Both professions sought after truth, and both tested carefully the evidence presented to them—lawyers by a process of cross-examination, medical men by ever closer and more accurate observation assisted by elaborate instruments. Cross-examination was rather repugnant to the popular mind because it represented the application of well known and tested principles by which the ordinary man was not guided in his own particular judgements and affairs; instead of relying on what was ascertained by accurate observation, the ordinary man was guided largely by emotional preferences, prejudices, and impressions which had persisted from his youth in spite of evidence that they were erroneously based. Lord Justice Atkin believed cross-examination, properly applied, to be the most effective means of ascertaining the truth whether as to a fact or a theory. In some branches of medicine—psycho-analysis, for example—cross-examination was one of the principal arts, pursued, he did not doubt, at times with great success. That it was an art which required cultivation and practice was illustrated in the courts when some litigant conducted his own case, and failed miserably in his attempts at cross-examining the other side. The Lord Justice went on to speak of the various ways in which the two professions could assist one another, and the great range of subjects, relating to both civil and criminal law, in which the law depended upon the information given by the medical man. In civil law these subjects included such large matters as marriage, injuries, insurance, and workmen's compensation. The general attitude of the law towards the medical man was to treat him, not as an advocate or as one supporting a particular thesis for its own sake, but as himself a minister of justice, anxious to assist the court at arriving at a true conclusion. To doctors who were called upon to give evidence he would say that it was of first importance for them to make sure whether they were speaking of something which they had ascertained as a fact or were simply putting before the court their impression or theory. Many topics of interest to both professions, he continued, were still outstanding. The most important was the great question

of insanity and the responsibility of the insane person for criminal acts. Medical men had not yet been able to define what they meant by insanity. The difficulty was as old as Hamlet, and the speaker was not sure that the definition of "true madness"—"nothing else but mad"—had advanced much further. But he hoped that at any rate in respect to criminal responsibility it would be considered a fair and proper thing to find irresponsibility when the crime was committed from irresistible impulse the result of a diseased mind, and he was himself awaiting the time when some legal authority would explain what the true position was in quite well authenticated cases. Another outstanding question was professional secrecy. The extreme claim for privilege probably could not be upheld. There was no protection for a medical man in respect of such matters, and the law would so remain, he had no doubt, until some doctor—might he say, some fanatical doctor?—in the witness box declared that the confidence existing between himself and his patient was as sacred to him as that between priest and penitent or lawyer and client, and that he was prepared to go to prison for the rest of his life rather than violate it. The question would then arise whether the conflicting claims could not be reconciled by something less than a complete obligation on the part of the doctor to make a disclosure when called upon. The lecturer also mentioned another question, which he said was too controversial to enlarge upon—the question whether medical men might not fairly claim to have decisions affecting professional conduct made subject to some judicial investigation, instead of being left to the decision of any tribunal which did not act upon legal principles and upon evidence which could be tested and controverted by cross-examination. That was a matter he must leave to the doctors. In conclusion, he declared that law, equally with medicine, had important preventive aspects. He was surprised and pained when, at an important medical dinner two years ago, the remark of the Lord Chief Justice that the ideal and practice of lawyers was to be peacemakers was received with derision. Lord Hewart's remark was perfectly true, however much opposed it might be to the "picture-house" view of the lawyer. Each profession had much to learn from the other, and each depended in a large measure on the other's confidence and goodwill.

#### METEOROLOGY AND MEDICINE.

IN the course of a communication on Indian meteorology, read before the Royal Society of Arts (Indian Section) on May 8th, Sir Gilbert T. Walker, late director of Indian observatories, mentioned the rapidly growing importance of the relation between meteorology and medicine. The meteorological department at Simla, he said, now issued warnings to the medical department of the Indian Government of the danger of sunstroke or heat apoplexy when the wet bulb temperature approached 85° F. It also collated information from various areas regarding rainfall, and was able to forecast in what parts of the Punjab malaria was likely to be serious, so that local arrangements could be made to combat the disease before it had actively developed. He showed a diagram covering several decades to illustrate the direct influence the rainfall of July and August had on the malaria of the succeeding October and November in the Punjab; in recent years this relationship had been less marked, owing, he thought, to the activity of the medical department in the administration of quinine. An attempt had been made to cool the air in the big Government buildings of India. Over the large part of India in which the air is dry during the hot weather the process of cooling by 15° would not be expensive if the necessary appliances were inserted when the buildings were being erected. On entering the cooled premises it might be desirable to wear

a light overcoat for a few minutes, but after that no difficulty would arise, and the circulation of fresh air at a moderate temperature would add considerably to the mental activity of the staff. In regions where the air was damp special arrangements would be necessary for drying it, like those generally employed in the cotton mills. In the subsequent discussion Sir Leonard Rogers repeated the well known results of his investigations into the distribution of leprosy, tuberculosis, and pneumonia in India in relation to rainfall, humidity, and winds, and also spoke of some more recent work on the incidence of small-pox. On working out the monthly figures for small-pox in India from 1877 to the present day, he found that small-pox outbreaks always occurred in the year following a year of deficient rainfall. In the case of eight different outbreaks of small-pox in Bombay, for instance, the rainfall in the year preceding the outbreak had been below the average. A great fall in the incidence of small-pox invariably occurred during the rainy season when the humidity was at its height, and Sir Leonard Rogers was of opinion that in years of exceptionally low rainfall the humidity did not rise high enough to bring about the customary decrease in small-pox, so that when the cold weather came there was, so to speak, a legacy of cases remaining to which was added the ordinary seasonal incidence, and with this as a basis an epidemic occurred.

#### ROYAL COMMISSION ON FOOD PRICES.

The Royal Commission on Food Prices, appointed last December, with Sir Auckland Geddes, G.C.M.G., M.D., as chairman, has presented a first report dealing with wheat, including flour and bread, and with meat; it was issued at the end of last week. If the Commission continues its inquiry it will deal on a future occasion with other articles of diet, including milk, fish, fruit, and vegetables. The chief recommendation is to set up a food council under the Board of Trade. The council would have no executive powers, but would supervise staple food trades and give publicity to precise information as to the stocks and prices of the chief foodstuffs. It would replace the existing food department of the Board of Trade, but would be autonomous and would report to the President of the Board of Trade, who would be the Minister responsible to Parliament for its actions. The Commission attaches much importance to the autonomy of the food council, which it is desired should act as a mediator between producer, trader, and consumer in reconciling for a common end interests which it does not regard as necessarily conflicting. The council, it says, would not be a new Government department administering Acts and regulations and thereby bound at all times by precedent and the letter of the law. Nevertheless it is difficult to see in what respects it would in practice differ from a new department of Government, and this is the view expressed by Mr. Ryland in a minority report. He considers, also, that the proposal would be a definite advance towards State socialism. The council would consist of a whole-time chairman and of eleven other members, of whom one would be nominated by the Minister of Agriculture, another by the Minister of Health, and a third by the Secretary for Scotland; four members would be appointed by the President of the Board of Trade on the ground of wide business experience; and the remainder would be representatives of the consumer—two (one a man and the other a woman) nominated by the Trades Union Congress, and two (one a man and the other a woman) nominated by or on behalf of the local authorities. "The primary duty of the food council would," it is said, "be to study the situation in regard to bread and meat supplies, and to keep the public fully informed by periodical reports as to the working of these essential trades. The food council's reports should be not merely statistical compilations, but

should provide a commentary on the trend of events and so far as possible explain the causes which lead to important movements in prices. For this purpose the council would need to collect information relating to production, import, consumption, and stocks, together with more precise information than is at present available with regard to wholesale and retail prices." One of the effects of giving wide publicity to this information would, the Commission hopes, be to steady prices and to stimulate supplies by timely warning if stocks showed a tendency to fall below the normal level. The Commission, however, believes that public apprehension will not be set at rest until the State has armed itself with the necessary powers to deal with antisocial action by monopolies, trusts, and combines. "But," it adds, "the danger of the abuse of monopolistic power is not confined to the food trades, and it would, in our view, be unwise to set up special machinery for dealing drastically, by the application of sanctions, with antisocial actions in these and not in other trades." The other chief recommendation of the Commission is an endorsement of that made by the Interdepartmental Committee on Meat Supplies in 1919 in favour of the compulsory registration of retail butchers. Registration would be carried out by the local authorities, but the food council would lay down the conditions of registration and the grounds on which it should be cancelled or temporarily suspended. The Commission has drafted the principles upon which the grant of registration would be determined. The first is "the due observance of public health regulations with regard to the sale of meat." The others have reference to the marking of meat and its accurate description, and the exhibition of a list of prices and charges for all classes and joints of meat on sale in the shop. The report has already come in for a good deal of criticism, for the most part foreshadowed in Mr. Ryland's minority report. The comparatively stable level of prices which existed for long periods before the war has given place to a fluctuating level of prices, so that consumers have lost their safeguard of practically customary prices. Mr. Ryland considers that the best way of meeting the difficulty is to strengthen that normal feature of the competitive system. The Ministry of Agriculture, the Board of Agriculture for Scotland, the Board of Trade, and the Ministry of Health each already has its statistical staff dealing with food matters, and Mr. Ryland advises that immediate steps should be taken for the formation of a co-ordinating committee comprising the principal officers of the statistical branches of the departments mentioned. A well informed public opinion is, in his view, the best safeguard of the interests of consumers, distributors, and producers alike; and the proposal for a co-ordinating committee would provide a basis for the formation of such opinion, and would involve practically no additional cost to the State.

#### THE PROSTHETIC HOSPITAL AT ROEHAMPTON.

THE new buildings of Queen Mary's Hospital at Roehampton, to which the Ministry of Pensions has transferred the patients and staff from Du Cane Road, Shepherd's Bush, were formally declared open by Queen Mary on May 6th. As was stated in the JOURNAL of April 11th, the surgical treatment of war pensioners and the fitting of artificial limbs will in future be carried on at Roehampton, and limbs will be supplied to civilians of certain classes. The Queen, who was accompanied by Princess Helena Victoria and Mrs. Baldwin, made a very thorough inspection of the whole establishment. The new wards, which have been erected on the northern side of the lawn at the back of the house, are of a pleasing appearance, owing largely to the spacious red-tiled verandahs which mask the southern gable-ends and afford open-air shelters; they will also keep the wards cool should we ever again experience

a spell of warm weather. The two operating theatres, with the necessary anaesthetizing, recovery, and sterilizing rooms, are situated at the back of the wards, with which they are connected by a corridor. They are well lighted and ventilated, and their skylights are cooled and kept clean by a flow of water over them. In addition to these new wards, which are built of brick, a number of the wooden huts which were built during the war for the accommodation of men who had undergone amputation have been redecorated and refitted for the reception of patients. The fine lawn has been somewhat encroached upon, but what remains is still of imposing proportions, and although it was necessary to sacrifice an ancient mulberry tree and, we believe, one of the smaller cedars, the beauties of the grounds and gardens are practically undiminished. The distance from the centre of London and the main railway termini is no doubt a drawback, but it will doubtless be more than balanced by the change from the now crowded and rather low-placed site at Shepherd's Bush to the purer air, nearly rural surroundings, and elevated position at Roehampton, where fogs are less frequent and of shorter duration than on lower levels, and not nearly so smoke-polluted as at Hammersmith.

#### ROYAL SOCIETY'S CONVERSAZIONE.

THE first conversazione of the year given by the Royal Society was held on Wednesday evening in the Society's rooms at Burlington House. Dr. A. H. Drew (Imperial Cancer Research Fund) contributed a most interesting series of microscopic slides illustrating tissue culture experiments. He demonstrated the initiation of growth in tissue culture by substances produced in damaged tissues, and also showed that differentiation in epithelial tissue was dependent on the presence of an adequate amount of connective tissue. A culture medium, the basis of which was a saline solution, was found to permit fragments of post-embryonic tissues to survive in a quiescent state for fourteen days or even longer if kept at body temperature. The addition to this medium of an extract of emulsion of kidney substance which had been incubated at body temperature for four hours started emigration and growth of the cells of the kidney (rat) within twenty-four hours. The emigrated cells appeared as a flat sheet surrounding the original central fragment of tissue. If a rapidly growing culture of connective tissue was implanted beside a kidney growth which was in this usual sheet form, the interaction of epithelium and connective tissue led to the formation of tubules resembling the normal renal tubules. Stratified squamous epithelium of the skin behaved in an analogous way, and if connective tissue was absent or only present in very small amount in the culture medium a sheet of closely packed spindle cells, resembling fibroblasts, resulted. If, however, connective tissue cells were incubated together with epithelial cells, the characteristic formation of epithelial pearls was observed. This same alternation between epithelial sheet growth and tubular gland growth was also obtained with an alveolar mammary cancer of the mouse. Dr. O. Rosenheim and Dr. J. C. Drummond (National Institute of Medical Research) demonstrated a colour test for the presence of vitamin A. A brilliant ultramarine blue colour reaction is given by the fat-soluble vitamin A present in cod-liver oil and butter when arsenic chloride is added to it. Other dehydrating reagents, such as dimethyl sulphate, trichloroacetic acid, benzoyl chloride, in the presence of zinc chloride give similar reactions, showing identical spectral absorption phenomena. This reaction has been used for the colorimetric determination of the growth-promoting activity of medicinal cod-liver oils and butter. Dr. H. W. Dudley and Dr. O. Rosenheim also demonstrated the peculiar crystals found in semen, known since 1865 as "Böttcher's crystals," though their presence

was originally reported to the Royal Society by Leeuwenhoek in 1678. These crystals, which are composed of spermin phosphate, are not specific to semen, but have been isolated from almost all animal tissues except blood, and also from yeast. It is thought possible that the wide distribution of this salt of spermin may have some biological significance. The International Western Electric Company demonstrated an electrical stethoscope which, in addition to providing the usual facilities, enables any number of persons up to 600 to practise auscultation simultaneously. An audiometer exhibited by the company enables measurements to be made of the sensitivity of any ear by relating its "threshold of audibility" to that of an average ear, as determined by experiment on a large number of persons whose powers of hearing were normal. An artificial larynx, also shown by the firm, is intended to restore vocal powers to patients from whom the larynx has been removed so that the trachea terminates at the base of the neck. Professor W. M. Thornton exhibited a miner's electric lamp which indicates and measures firedamp. A thermal device involving the use of a platinum preparation enables the percentage of methane in the air to be both registered and measured by a very simple manipulation. Although electric lamps are widely used in coal mines, they have not hitherto been made capable of indicating or measuring firedamp. Dr. R. S. Clay and Mr. Thomas H. Court demonstrated the Lucernal microscope of Samuel Washbourn, which is 120 to 130 years old, and has the usual pyramidal wooden body; it is mounted on an elaborate collapsible mahogany stand. Mr. George H. Gabb showed a telescope bearing the name and date "Jacob Cnigham, 1661"; it is, so far as is known, the oldest optical instrument existing in this country to which a date can confidently be ascribed. The instrument is of the curious trumpet shape characteristic of many of the smaller telescopes of that period. Other exhibits included fused quartz ware, contributed by the Thermal Syndicate, Ltd., and comprising laboratory equipment of various kinds, mercury vapour lamps, hypodermic syringes for flame sterilization, and a silica valve for naval wireless telegraphy. During the evening cinematograph demonstrations were given to illustrate the main characteristics of the Brownian motion of minute particles.

#### ROCKEFELLER MEDICAL FELLOWSHIPS.

THE Rockefeller Medical Fellowships for the academic year 1925-26 will shortly be awarded by the Medical Research Council, and applications should be lodged with the Council not later than June 10th, 1925. These fellowships are provided from a fund with which the Medical Research Council has been entrusted by the Rockefeller Foundation. Fellowships are awarded by the Council, in accordance with the desire of the Foundation, to graduates who have had some training in research work in the primary sciences of medicine or in clinical medicine or surgery, and are likely to profit by a period of work at a university or other chosen centre in the United States before taking up positions for higher teaching or research in the British Isles. A fellowship will have the value of not less than £350 a year for a single Fellow, with extra allowance for a married Fellow, payable monthly in advance. Traveling expenses and some other allowances will be made in addition. Full particulars and forms of application are obtainable from the Secretary, Medical Research Council, 15, York Buildings, Adelphi, London, W.C.2.

THE twelfth International Physiological Congress will be held in 1926, at Stockholm, from August 3rd to 6th. Professor Johansson will be president, Professor Liljestrand honorary secretary, and Professor Santesson honorary treasurer.

MAY 16, 1925]

# BRITISH EMPIRE EXHIBITION.

## BRITISH EMPIRE EXHIBITION, 1925.

WEMBLEY EXHIBITION was reopened by the King on Saturday, May 9th, under weather conditions that were rather mixed, but were certainly less depressing than the average of last year. If some rain greeted the opening ceremony, yet the sun shone with greater warmth than was usual in 1924.

### MEDICAL EXHIBITS.

The Exhibition as a whole may be summed up tersely as having become more domesticated: it is less startling than last year, but more interesting. This is exemplified, for instance, in the Medical Section, which we described in our issue of April 11th, 1925 (p. 703). Here the horrors of jungle and other tropical diseases, which were such an outstanding feature in the section of 1924, have given place in 1925 to the triumphs of therapeutics and prophylaxis. Domestic hygiene, hidden away last year in a little-frequented corner, has now expanded both in extent and interest and occupies deservedly one of the finest sides of the Government Pavilion. The historical side of medicine receives more consideration this year, and it may be added in this connexion that Messrs. Burroughs Wellcome and Co. are exhibiting a tabloid medicine chest used in the Everest expeditions of 1921, 1922, and 1924, which, after many thousand miles of travel and accidents, is still fit to do duty with a fourth expedition. The firm is also exhibiting a group of the actual medical and first-aid cases which were used by the pioneer aviators. When Blériot crossed the Channel in a monoplane in 1909 he carried with him a tabloid first-aid outfit. This, with the outfits carried by Sir John Alcock in his flight across the Atlantic, by Ross Smith from England to Australia, and by Squadron Leader Maclaren in his attempt to travel round the world, are also being exhibited, as is the case which accompanied R.34 in the first airship flight from England to America. Other exhibits include the tube of solidified ginger essence carried by Peary in his last dash to the North Pole, and the cases used by Amundsen and Scott in 1912.

### PALACE OF ARTS.

The Palace of Arts at Wembley is of wide interest, representing as it does so many periods and forms of art. There is a very interesting retrospective collection of oil paintings, with examples of the work of Holbein, Reynolds, Gainsborough, Romney, Hogarth, Lawrence, Millais, Sargent, and many others. The rooms devoted to modern British art are fairly representative, though there are no really important works and many of the pictures are not quite recent. The beautiful study of two figures for "A Western Wedding" shows Orpen at his best. "A Norfolk Landscape" by Arnesby Brown, "The Lady with a Fan" by Augustus John, "The Tortoise" by William Nicholson, "The Check Shawl" by Algernon Talmage, and "A Lady in Black and White" by F. C. B. Cadell, are but a few of the delightful works which should be studied at leisure in this part of the Exhibition.

The standard of the modern prints is high, and a great many delightful woodcuts are shown. The modern illustrations are chiefly by a few of our best known illustrators, the most entertaining being the collection of caricatures by Max Beerbohm. Of the works in the Sculpture Gallery we may mention Frank Mowbray Taubman's "The Steps of Life," and Sir Hamo Thornycroft's "The Kiss." It is of special interest to have two rooms devoted respectively to Australian and South African art, and two to Canadian art. In the attractive Canadian rooms we were impressed with the freshness of style, and particularly liked "Autumn, Ottawa Valley" by Graham Norwell (lent by the National Gallery of Canada), and "Village in the Laurentian Mountains" by Clarence Gagnon. Australia is well represented, also "The Quarry" by J. D. Moore, and many others. The work of the South African painters seems to be rather immature, but their colours are fresh, and "Market Carts" by D. Kay and several others are pleasing. Unfortunately some of the special rooms were not

finished on private view day. The bronze "Orpheus," by J. M. Swan, is in a perfect setting in the beautiful tapestry room, whose walls are hung with tapestry designed by Burne-Jones and executed at the William Morris works (1898-99). The Basilica, though unfinished, gives a most pleasing general effect. The apse decoration this year is done by Colin Gill; J. Kerr Lawson's decorative panel in coloured paper is very effective, and so is the altar tomb designed by Frederic Etchells. Special attention might well be paid to the Applied Arts Section, as this should help the public to realize the advantage of beautiful things for ordinary use. There are many beautiful examples of pottery, metal work, hand-woven material, and other textiles. Mr. Rowley shows some of his decorative wood panels, designed by W. H. Chase. The Royal Mint shows several cases of medals, many designed by young artists, and the inn signs exhibited by Captain Kettleworth should not be overlooked. The modern jewellery is very good, and it is a pity we do not see more posters on our hoardings like those in the Poster Room.

## Non et Vetera.

### "PARSON MALTHUS."

MANY writers have been praised and blamed by those who have never read a line of their works. What percentage of the teachers of clinical medicine who acclaim Hippocrates the Father of Medicine and Sydenham the English Hippocrates have read the works of either Hippocrates or Sydenham? It may be doubted whether all young graduates in biology have read the *Origin of Species*. In such instances perhaps little harm is done. Hippocrates, Sydenham, and Darwin are names indeed associated with ideas once hotly controverted, but the ashes of the fire have long been cold. Judgement was passed long ago upon the Cnidians, upon the advocates of a heating regimen in small-pox, and upon Samuel Wilberforce and St. George Mivart. On these matters second-hand information is incomplete, but unbiased. This cannot be said of Malthus's work; the controversy he provoked is still raging, while it is still true that more people praise (or blame) him than read his books.

The *Essay on Population* is not, indeed, inaccessible. It was reprinted some years ago in "Everyman's Library" with a concise and useful introduction by Mr. W. T. Layton; but, with many merits, the style is not attractive—one cannot read it for pleasure. It is hard to say precisely what is lacking; perhaps there is a certain coldness uncompensated by the satisfaction of the reader's vanity due to grappling with difficult technical investigations. There are indeed difficulties, but not on the surface; although the book is largely statistical it contains very little algebra.

Almost forty years ago the distinguished economist Dr. James Bonar published a volume of elucidations, entitled *Malthus and His Work*; this he has now reprinted with important additions, in particular a biography, and the book supplies just what was wanted. It traces the development of Malthus's thought and humanizes the philosopher. Anybody who has read Dr. Bonar's volume will approach the *Essay* in a sympathetic mood and will assess its virtues and shortcomings more justly.

It is nearly a hundred years since the last edition published in its author's lifetime was printed; in that century much has happened. But living, as was Malthus, under conditions of great industrial distress following a terrible war, we ask ourselves the same questions. In 1815 there were perhaps fewer political rhetoricians proclaiming the arrival of a new heaven upon earth than in 1918; nobody, we think, said anything about providing homes for heroes; nobody pretended that a peace was going to be made upon any newer or nobler principle than that of getting as much for oneself as one could; certainly nobody supposed that the victors would be able to extract a large war bonus from the vanquished. But if far fewer hopes were aroused only to be disappointed, the amount of physical distress was without

doubt much greater, proportionally, in the years after 1815 than in the last six years.

We are all pessimists now; but however heartily we anathematize (in accordance with our political sentiments) the Coalition, the Bonar Law, the Baldwin, or the MacDonald Ministry, we should at least place this to the credit of one and all, that England in 1918-24 has not been so harsh a world for the vast majority as was the England of 1815-21.

Yet the Sphinx still asks her riddle; it is still a question whether population is not outrunning the means of subsistence, using the phrase less literally than did Malthus. His thought envisaged population pressing upon the actual physical margin of subsistence; we substitute for the notion of bare subsistence that of a standard of life, deemed the minimum permissible, and ask whether our growth of population is compatible with the maintenance of that standard. Since Malthus's day the concept of checks to growth of population other than those he discussed has been considerably enlarged. Dr. Brownlee has for some years sustained the thesis that fertility waxes and wanes following laws wholly beyond the power of man, whether acting consciously or unconsciously, to deflect. Professor Raymond Pearl has rediscovered and greatly extended a hypothetical law of population growth proposed many years ago by Verhulst, and, in his recent presidential address to the Royal Statistical Society, Mr. Udny Yule, as we have already noted,<sup>2</sup> has expounded this principle with his customary lucidity and generally approved it; the upshot being to regard "the growth of population as a biologically self-regulating process; indeed, a process of which the regulation is extraordinarily sensitive." This doctrine leads to the conclusion of Burke—"Let us be saved from too much wisdom of our own, and we shall do tolerably well." But it will not pass without challenge, and in the next years we may expect a large output of literature on the population problem. Anyone who intends to take part in the fray should read, or reread, Dr. Bonar and Malthus.

## ROYAL COMMISSION ON LUNACY AND MENTAL DISORDER.

### EVIDENCE OF THE MEXICO-PSYCHOLOGICAL ASSOCIATION.

(Concluded from page 889.)

#### Psychiatric Education and Research.

On the second day of the sitting Sir FREDERICK MOTT gave evidence on the need for better provision for psychiatric education and research. He said that as long ago as 1907 he was convinced that a diploma in psychological medicine would prove as valuable as the diploma in public health. Just before the war Cambridge instituted such a diploma, and its example had since been followed by many of the universities. In the London county mental hospitals the possession of the diploma had become indispensable for senior appointments. Universities did not provide special courses unless there were a sufficient number of students; recently in Manchester, for instance, a course was not proceeded with because not enough candidates were forthcoming. He agreed with Sir Humphry Rolleston that it would be desirable to standardize the examinations of the different bodies. In reply to Sir David Drummond, who commented on the large amount of time devoted in the Maudsley syllabus to theoretical work and the comparatively small amount to practical, he said that the diploma was given only to men who had served a year or two in an asylum, so that it was rather on the theoretical side that they needed instruction. But at Maudsley arrangements were made for cases from the London asylums to be brought up for illustration and discussion. He mentioned the doctorate in psychological medicine of the University of London, and said that this at present had only three holders.

Sir F. Mott next spoke on the need for research. He favoured a plan whereby a group of asylums would have, apart from their own separate laboratories, a central laboratory, like that in Birmingham, which it was hoped would be the centre for the mental hospitals of the Midlands. He pointed out that in this country, while a large amount of money was spent in medical research in other directions, almost no one had come forward to assist the investigation of insanity except Dr. Maudsley, who gave half his fortune earned in his practice, and in Birmingham Sir Charles Hyde had founded a lectureship in psychology and had given a certain sum of money for a scholar in the research laboratory. Asked by the Chairman why mental sciences remained "a Cinderella without a Prince,"

Sir F. Mott said that he thought it was attributable to the persistence of old metaphysical ideas with regard to mental diseases—people had not got away from demonology yet.

Dr. EDWIN GOODALL thought that there was no barrier to the local authorities who were responsible for public asylums assisting financially in the setting up of such laboratories as Maudsley, Birmingham, and Cardiff. At Cardiff already large sums of money had been spent on pure research. The Chairman said that legally there was no obstacle to local authorities spending money on such objects within their own area, but difficulties would arise when it was proposed to spend money on a laboratory or other institution outside their own area. Dr. Goodall went on to speak of the inadequacy of the present teaching of psychiatry, which had not greatly advanced since the time, thirty years ago, when he was a student. Save for the Bethlem Royal Hospital and now the Maudsley Hospital, only "asylums" were available for students to go to, and at asylums the cases such as they would be required to deal with in practice were very rarely to be seen. He compared the teaching of students in England, to its disadvantage, with the teaching at the University of Utrecht. The lack of teaching facilities here resulted in the appointment to asylums of junior medical officers who knew very little of mental disorders.

Mr. MICKLEM asked whether it was the suggestion of the association that the local authorities should be asked to afford moneys for the upkeep of central laboratories. Sir F. Mott said that that would be very desirable. In return the local authorities would be able to have investigations carried out with regard to epidemics, for example, arising in asylums, or, indeed, any form of research work, and students would have facilities for instruction. Lord Russell said that the Commission had heard a Lancashire witness who had objected strongly to directed research. Sir F. Mott said that the director of a laboratory would not interfere with any research he thought likely to be of use, although he would desire to have control over what was published from his laboratory. Lord Russell said that the objection of the witness to whom he had referred went further; he had even deprecated team work, believing that research should be left to individual inspiration. Sir F. Mott argued that this was not a true view. The most valuable achievements had been the result of team work, and could have come about in no other way. He would not, however, agree that the Board of Control should exercise control over research at all; that was not its province.

Dr. COLR, at the conclusion of the evidence, said that he hoped the Commission would recommend that in some way Parliament would allow research to be encouraged at asylums. Mr. MICKLEM, who had meanwhile taken the chair, said that the Commission fully appreciated the views which the representatives of the association had so well expressed.

A valuable memorandum was submitted to the Commission by Dr. J. R. LORD on the legal and administrative position of psychiatry in some European countries and in America, and another by Dr. MENZIES on the constitution of the central authority in mental health. Dr. Menzies's view was that the Board should consist of five medical and two legal members, and that the medical members should be paid not less than £2,000 a year. For a pension the years served under a local authority should be counted. The Commissioners should be experts of the highest standard of medical and scientific attainment.

## England and Wales.

### A NEW HOSPITAL AT WOOLWICH.

A new general hospital is to be erected by public subscription at Shooters Hill, in memory of residents of Woolwich and the adjacent districts who died in the war. The new institution will serve a population of 200,000, the nearest general hospital being four and a half miles away. It is proposed that the foundation stone of the first section of the hospital shall be laid by the president, the Duke of Connaught, on July 7th. This section will provide accommodation for 110 beds, and include the administrative block, operating theatres; radiological and electrotherapeutic departments, and a pathological laboratory. The total cost of the first section, including equipment, is approximately £200,000, towards which £170,000 has been raised, £80,000 of which was received in small sums locally. A substantial grant has been made by King Edward's Hospital Fund, and Viscount Burnham opened a fair and festival in the Woolwich Town Hall on May 6th, with a view to obtaining sufficient money so that the hospital may open free from debt. The second and third sections will increase the accommodation up to 318 beds.

**ROBERT DAVIES NURSING HOME, LIVERPOOL.**

Through the munificence of the late Mr. Robert Davies, a shipowner of Liverpool, a nursing home has been established for the exclusive use of middle-class patients of limited means. A mansion was acquired in Sandfield Park, West Derby, near Liverpool, and after suitable alterations was opened in January last. It stands in twenty acres of ground, secluded from the noise of a large city, and yet within easy access from all districts. Thirty patients can be accommodated, and the loftiness of the rooms, of which there are three on the first floor and six on the second floor, ensures ample air space. All these rooms give the impression of comfort in surroundings to which this class of patient is accustomed. Each bed is capable of being screened by an ingenious arrangement, ensuring privacy and sacrificing nothing of the nursing requirements of the patient. The lavatory arrangements are complete in every respect, and perfect ventilation is ensured. There is a lift for bed cases, and the corridors are wide. Heating is central, and the whole building is thoroughly dry. There is a complete operating unit, consisting of surgeon's dressing room, sterilizing room, anaesthetic room, and operating room. The last has a northern aspect, a terrazzo floor, and the operating table as well as the fittings are of the latest type. In fact, although designated a home it is in reality a hospital with all the amenities to which these patients are accustomed in their daily life. Patients are attended by their own medical men, and on them devolves the onus of recommending applicants for admission; this recommendation is submitted to the honorary secretary for confirmation. No neurasthenic, infectious, phthisical, or mental case will be admitted, and maternity cases must receive the special permission of the committee. The charge for each patient is three guineas a week, which includes nursing, surgical dressings, and medicaments. The honorary secretary is Mr. Frank White, 12, St. George's Crescent, Liverpool, from whom full particulars can be obtained. It would appear that this home really meets, not only the wants of many patients, but those of medical men, who know only too well how expensive on the one hand, and the objection to entering a hospital and being no longer under the care of their own medical men on the other, militate against the patients' speedy convalescence.

**ROYAL ALBERT INSTITUTION FOR THE FEEBLE-MINDED, LANCASTER.**

New buildings are being added to the Royal Albert Institution for the Feeble-minded at Lancaster, and it will soon be possible to accommodate about 1,100 patients. The Cavendish Reception House, which has been built at a cost of £6,624 apart from furnishing expenses, will, it is hoped, be ready for occupation early in June. An open-air school for use during the summer months has been completed recently at a cost of £850, and a start will shortly be made with the erection of six new blocks to house low-grade defectives who require little more than ordinary supervision. Each of these blocks will accommodate about fifty patients, and will be associated closely with the central administrative block. At present the institute contains 788 patients, of whom 308 are from Yorkshire, and though it appears that the flow of payments by patients, donations, and subscriptions from this county during the last year was insufficient for the maintenance of these patients, yet the deficit is more than covered by the income arising from invested Yorkshire contributions. The deficit was due to an increase in both the number of Yorkshire patients and the cost of their maintenance. Since 1878 the members of the various Yorkshire associations have collected over £33,000, and the ladies' associations of the seven counties which are co-operating in the support of the Royal Albert Institution have raised a sum of over £112,000.

**CENTRAL MIDWIVES BOARD.**

The Central Midwives Board for England and Wales met on May 7th, Sir Francis Champneys presiding. At the penultimate five cases were dealt with and all the midwives concerned were removed from the roll. The principal business dealt with by the standing committee included consideration of the proposed new rules as to training, pre-

pared by the Central Midwives Board for Ireland. The following reply was agreed on:

That the Board has no observations to make on the draft rules, other than to state that, as at present advised, it does not consider the training which has led to the appearance of the name of a candidate on the general part of the register (otherwise than by passing the examination of one of the joint nursing councils) or the supplementary part of the register, containing the names of sick children's nurses, as justifying a reduction in the full period of midwifery training required by the rules of the Board, and her admission to the roll under such conditions.

A letter was received from the honorary secretary of the Welsh branch of the Society of Medical Officers of Health, stating that the branch approved of the holding of a conference between representatives of local supervising authorities and members of the Board to discuss points raised out of the administration of the Midwives Act, but suggesting that the Welsh authorities should not be grouped with English authorities, and also suggesting the desirability of the Board approaching the Welsh Board of Health with a view to a joint conference with Welsh authorities.

**Scotland.****FINANCIAL POSITION OF EDINBURGH UNIVERSITY.**

At a meeting of the General Council of Edinburgh University on May 6th the Principal, Sir Alfred Ewing, stated that during the past half-year a remarkable and agreeable change had come over the University's finance; as regarded both capital and income there had been an improvement of the most significant kind. Six months ago the University had been involved in a heavy burden of debt contracted in respect of the new chemical laboratory; this burden had been so heavy that it had seemed impossible to contemplate any fresh schemes of expenditure for many years to come, but the situation had been entirely altered by the great generosity of Sir Alexander Grant and other donors. The extinction of the debt would still be a matter of some time, but it would now be possible to enter with confidence on enterprises for new buildings the University greatly needed. With regard to annual revenue, the Chancellor of the Exchequer had allowed the inclusion in the estimates for the current financial year of a supplementary sum to the annual grant for the universities of Great Britain, although it was not yet possible to say exactly what the amount would be. It would represent substantially the same amount as that by which the annual grants had been reduced some years ago. These two things would ease the financial position of the University and enable it to increase its activities in other directions, but there would remain the necessity of impressing on the friends of the University the fact that it still had need of help. Reference was also made to the founding of a chair of archaeology, for which funds had been left by the late Lord Abercromby. The Business Committee of the council submitted a report recommending the council to approve of a proposal to institute an honours course in experimental psychology for the degree of B.Sc.

**MAN'S EVOLUTION.**

Sir Arthur Keith has given a course of Munro Lectures before the University of Edinburgh. His subject was the evolution of man as told by his fossil remains. In his first lecture, given on May 1st, he said that if nothing more was to be known of the origin of the British people than was contained in the history of classical writers, the work compiled in the sixteenth century by that prince of Scottish scholars, George Buchanan, would be the standard treatise on British origins. He was right in holding that the early Scots were a Celtic-speaking people who inhabited the centre of the Continent and were the first to reach the British Isles, coming by two routes: one party, after spending several generations in Spain and France, entered by the west, and the other by the eastern shores, after dwelling for centuries in North Germany. The first man in Scotland to write history in a new way had been a distinguished native of Edinburgh, Daniel Wilson. He was born in 1816, and, when still a young man, Scandinavian

antiquaries were making the wonderful discovery that history could be read from ancient tombs as well as from ancient manuscripts. They dated tombs according to the kind of implement found in them, and accordingly could assign the skulls and skeletons found in these tombs to the stone, bronze, or iron period. Wilson's pioneer work, *The Archaeology and Prehistoric Annals of Scotland*, appeared in 1851. In it he maintained that there had been a succession of races in Scotland; at least two had preceded the coming of the Celts. The next progressive step in the writing of pre-history had been made by the archaeologists of France in the sixties of last century, who investigated the debris on the floors of caves in which their remote ancestors had lived. These cave dwellers had lived with animals now extinct which were adapted for life in the coldest of climates, and the stone implements were of a much older kind than those found in the tombs of Scandinavians. Sir John Lubbock had named the kind of stone implements used by the Scandinavians "neoliths," and the weapons of the caves "palaeoliths." In Scotland the land had risen some fifty feet since neolithic times, and the carse lands contained stranded whales, sunk canoes, and the implements of early neolithic Scotsmen; the same kind of thing had been found in the valleys of the Somme and the Thames. These deposits carried man's history back to the beginnings of the Pleistocene period, at least 100,000 years ago. In his second lecture Sir Arthur Keith referred to researches regarding pre-history in Crete, which had covered a period of nearly 7,000 years, from 8000 to 1200 B.C., and to early civilization in Babylonia and Egypt. There was no evidence, he said, of any influence exerted by these civilizations upon the ancient inhabitants of Britain. The people buried in our oldest tombs differed from the earliest natives of Egypt and of the lands to the east of the Levant in the characters of the skull and face. The Scandinavians and Egyptians of to-day were at opposite ends of the European scale of racial types, and between them lay a series of intermediate types, the northern or Nordic type fading gradually into the Egyptian. The people of Britain had belonged most definitely to the Nordic end of the scale. Until 2,000 years ago cemeteries had not been required for the burial of the dead, who were laid in isolated family tombs. The explanation of this fact was to be sought in the sparsity of English communities down to the centuries which preceded the coming of the Romans. The third lecture dealt with the arrival of modern man in Europe. There was a regrettable tendency among students of human races to give up the use of the term "Caucasian," which indicated the type of man who now occupied not only Europe but also Western Asia, from Ireland to Afghanistan, and extended a short way into Northern Africa. "Mousterian" was a very definite term, standing for a period of human history which began in Europe before the last forward creep of the Arctic ice about 40,000 B.C. and ended about 20,000 B.C., when there was a respite in European climatic conditions. This term denoted also the people of that time who lived in caves, fashioned stone implements, and buried their dead in the floors of the caves. These people were separated by a great structural gulf from the Caucasian race—a greater gulf than that which separated a pronounced negro from the fairest of Scandinavians. Ten caves or rock shelters had been found dating from this Mousterian period; of that period the best known representative was the Neanderthal man. The culture which the Caucasian pioneers brought to Europe got the name of Aurignacian; they had great skill as hunters, artisans in stone and bone, and artists. These Caucasians of the Aurignacian period were not only our ancestors, but they had brought with them the foundations of our way of living. Their burial customs, their ornaments, and their implements had remained almost unchanged for several thousand years, as could be seen from caves at Mentone, Cromagnon, and from a large hunting-station, extending over several acres, which was now being explored in Moravia. At the close of the Ice Age England was joined to the Continent. The North Sea was a bay, and the Caucasians could make their way from Germany to Scotland, so that the types of implement found in caves at Oban and in the raised beach at Oronsay belonged to the same order of culture as the implements of Baltic lands. On

this reckoning Scotland had been an inhabited country for about 10,000 years. If Scotland had already had pre-glacial inhabitants, they were not men of the Caucasian stock. Of this earlier race only one human skull had been found—in the McArthur cave at Oban. This skull represented a type which still abounded among people of the south and west of Scotland and in Ulster—men with long massive faces, of whom, if one might dare to cite well known and justly esteemed modern representatives, one might call to mind the faces of Lord Carson and Sir Auckland Geddes. Throughout the vicissitudes of the Ice Age the southern parts of England beyond London and Bristol had always been habitable, and some half-dozen Englishmen of the Ice Age were known. Their culture and their bones had been dug out of caves in Derbyshire, the Mendips, and from deposits in the Thames valley.

#### CLEAN MILK.

Several Scottish papers in the past week have published an article by Dr. Chalmers Watson dealing with graded milk, with special reference to hospitals. He believes it probable that more than two-thirds of disease in a children's hospital arises directly from defective nutrition, and very largely from the impurity of the milk supply. At the present time other countries are, he affirms, ahead of Britain in the appreciation of the importance of this subject, especially America and Denmark, where the annual milk consumption is estimated to be three times as great in proportion to population as in this country. Until quite recently the milk consumer was accustomed to buy his or her milk for domestic purposes at a flat rate, irrespective of anything but the quantity purchased. It did not matter to the consumer whether the milk itself was good, bad, or indifferent, although a standard of chemical composition, which was comparatively low, was demanded; the requirement was 3 per cent. of butter-fat and 8.5 per cent. of other solids. The milk, however, might be comparatively clean or extremely dirty; it might or might not be infected with living tubercle bacilli, or it might have infections of various kinds; it might keep sweet for several days or it might go sour in a few hours; and none of these important considerations made any difference to the price charged to the consumer. It had not been realized that milk might be of great value, of little value, or actually dangerous, until, as the result of inquiry by various committees—and we may add of the strenuous efforts of the medical profession—the Government took action by legislation in 1922 to standardize definite grades of milk. A previous grading had been established by the Food Controller in consultation with the Ministry of Health and the Scottish Board of Health. This came into force on March 14th, 1920, and was described in detail in our issue of March 6th, 1920 (p. 336). The more recent grading of milk was defined by the Minister of Health in the Milk and Dairies (Amendment) Act, 1922, which was reported in our columns of December 23rd, 1922 (p. 1239), and an explanatory memorandum, issued later by the Ministry of Health, was discussed on March 10th, 1923 (p. 433). The grades of milk now recognized are as follows:

1. *Certified milk* from herds every animal in which must have passed the tuberculin tests specified in the appendix to the memorandum before the licence was granted, and thereafter at intervals of six months. Every animal reacting to the tests was forthwith to be removed from the farm, and no animal was to be added to the herd unless it had passed the tests. The milk must be bottled on the farm immediately after production, the bottles being closed by a cap forming a seal, and bearing the address of the producing farm, the day on which it was produced, and the words "certified milk." The milk must not contain *Bacillus coli* in 1/10 c.c.m., or more than 30,000 bacteria per c.c.m. It must not be pasteurized.
2. *Grade A (Tuberculin Tested) Milk*.—The regulations in this case are similar to those for certified milk as regards the testing of the herds and prohibition of pasteurization, but otherwise production and distribution are governed by the regulations for Grade A milk.
3. *Grade A Milk*.—The herd must be examined once every three months by a veterinary surgeon. If the milk is pasteurized the fact must be stated on the cover of the containing vessel. The milk must not contain *B. coli* in 1/100 c.c.m., or more than 200,000 bacteria per c.c.m. The milk must be distributed from the farm in an unventilated sealed container on which is recorded the address of the farm, the day of production, whether produced morning or evening, and the words "Grade A Milk."

4. *Pasteurized Milk*.—The milk must be retained at a temperature of not less than 145° and not more than 150° F. for at least thirty minutes, and then must be immediately cooled to a temperature of not more than 55° F. The milk must not be otherwise treated by heat, and must not be pasteurized more than once. After pasteurization there must not be in the milk *B. coli* in 1/10 c.cm., or more than 30,000 bacteria per c.cm.

Dr. Chalmers Watson points out that the pasteurization has the defect of diminishing the nutritive value of the milk, and makes a fifth grade for ordinary milk, which may contain tubercle and other bacilli, and also grosser impurities. Such milk, it is held, is only suitable for use when cooked. Dr. Watson admits that laudable attempts have been made by practical dairymen to raise the standard of milk, but says that the producer gets no material value for his efforts in this direction. He looks on the education of public opinion as the one stimulus required to bring about a very necessary reform, and that this would also be of value in assisting the medical profession to achieve the improvement it desires. Examples of action in this direction are given, as, for example, the recent work carried on by the Town Council of Edinburgh, which was noticed in the *BRITISH MEDICAL JOURNAL* of May 2nd, 1925. Dr. Chalmers Watson states that none of the leading general hospitals or children's hospitals in this country have yet given this subject serious consideration, and he considers that the time is ripe for an effort on the part of the medical profession in the interests of preventive medicine more strenuous than has yet been made.

#### NEW EAR, NOSE, AND THROAT HOSPITAL FOR GLASGOW.

H.R.H. Prince Henry paid his first visit to Glasgow on May 2nd, when he fulfilled a number of public engagements, including the laying of the foundation stone of the new Ear, Nose, and Throat Hospital in St. Vincent Street, which is at present in course of erection. Sir John Hunter, K.B.E., chairman of directors, stated that through a special effort £54,000 had been raised out of a total cost of £60,000, and it was hoped when the building was put in use it would be free of all debt. The hospital, when finished, would contain 42 beds, and would have the most up-to-date equipment. His Royal Highness unveiled a memorial bronze tablet on the front of the building.

#### APPOINTMENTS IN EDINBURGH.

Mr. Keith Paterson Brown, F.R.C.S.Ed., has been appointed assistant surgeon to the Edinburgh Royal Infirmary, and Mr. Norman M. Dott, F.R.C.S.Ed., and Miss Gertrude Herzfeld, F.R.C.S.Ed., surgeons to the Royal Edinburgh Hospital for Sick Children. Mr. Dott was assistant to the Church of Scotland Deaconess Hospital and Chalmers Hospital, and Miss Herzfeld has acted for some years as assistant surgeon to the Sick Children's Hospital and junior surgeon to the Edinburgh Hospital for Women and Children.

## Ireland.

#### FUTURE OF LOCAL GOVERNMENT.

At a recent meeting of the Dublin Rotary Club Mr. E. P. McCarron, Secretary to the Local Government Department, spoke on the future of local government in the Irish Free State. His object, he said, was to provoke a quickening of interest in some of the more important basic facts underlying the system of local government at present in operation. A modern American authority, referring to local government in that enlightened country, had said that the business was in general the most poorly managed in the world. Until the dawn of the twentieth century the business of government was characterized by a lack of interest on the part of stockholders and customers, by extravagance in the expenditure of money, and by lack of business method on the part of officials. The root of the matter was that no community had in matters of local concern yet succeeded in reconciling two fundamental principles—first, that all government, local as well as central, must be based on government by the people; and secondly, that grave evils could not be eradicated if their

causation could not be traced with precision to particular individuals on whom responsibility could be effectively placed. The corrective influence of the Dail tended increasingly to remove apathy from officialdom, a term which at one time was supposed to connote a place or state of rest. Another powerful influence for change was the ever-growing perception of the fact that all men must conform to certain regulations that were necessary to the health and well-being of others. The present immunity from such virulent diseases as cholera and typhus, and the well maintained decline in mortality rates from tuberculosis, could not have been possible without general measures independent of the fluctuating views held individually in parochial units. The bill of health of the Saorstát was a national matter, and an asset worthy of development. To put it on a higher plane, a country with considerable exportations of food commodities could not afford to delay too long in unifying and co-ordinating its various public health services. The Department of Local Government was becoming more and more convinced of the value of preventive expenditure, especially in matters of public health. The centralization of health and road matters already effected in the Local Government Act of the present year should have the effect of eliminating unproductive expenditure and of focusing criticism when it was deserved on parties who could not afford to ignore well grounded complaints. Health matters would be completely centralized in the county board of health, and the county medical officer, it was hoped, would be entirely independent of local influence. There appeared to be some promise that in the immediate future the business of local government would be allowed to proceed unfettered by any dividing lines arising out of political views. Representatives of the public had ungrudgingly in the past voluntarily done useful work, and in the time that was coming he hoped that there would be a great extension of voluntary workers in social activities. It was wonderful how much public economy could be achieved by voluntary workers.

#### DR. STEEVENS'S HOSPITAL, DUBLIN.

In his *History of Doctor Steevens's Hospital* Dr. T. Percy C. Kirkpatrick has given us a work which is a valuable contribution to the history of medicine in Dublin during the last two hundred years. At the beginning of the eighteenth century there was practically no other provision for the treatment of the sick poor in either Great Britain or Ireland than that provided—a very important exception—by St. Bartholomew's and St. Thomas's Hospitals in London. The Jervis Street Hospital, founded in 1718, was the first of the modern Dublin hospitals. Richard Steevens, President of the College of Physicians of Ireland and professor of medicine in the University, died in 1710, leaving directions in his will for the building of a hospital for the sick poor of the city. Owing to the energy of that remarkable woman, his sister, Grizel Steevens, the foundation stone was laid in 1720, but it was not until 1733 that the hospital was finally declared open.

The book contains an account of the lives of the most eminent physicians and surgeons connected with the hospital during the two hundred years of its existence, such as Richard Helsham, the friend and physician of Swift, and professor of natural and experimental philosophy at Trinity College; Edward Worth, who left a valuable library and £1,000 to the hospital; Bryam Robinson, described by Sprengel as one of the most celebrated iatromathematicians of his time; and lastly Abraham Colles and William Cusack, who did for surgery at Steevens's what Graves and Stokes did for medicine at the Meath. A medical school in connexion with the hospital was founded in 1857, but came to an end in 1880. Among other chapters of interest we may allude to those on the early history of Dublin hospitals, on fever in Ireland in the eighteenth century, on the relations of Dean Swift with the hospital, and on the early history of nursing. Dr. Kirkpatrick's book is illustrated by portraits of physicians and surgeons connected with the hospital, as well as by photographs of the buildings and wards at different dates.

<sup>1</sup> *The History of Doctor Steevens's Hospital, Dublin, 1720-1920.* By T. Percy C. Kirkpatrick, M.D., M.R.I.A. Dublin: University Press, 1924. (Double cr. 8vo, pp. xvi + 397; illustrated.)

An appendix contains lists of physicians, surgeons, and other members of the staff of the hospital from its foundation until the present day, as well as of contemporary judges, ecclesiastics, and others holding high official positions in Dublin.

#### ULSTER MEDICAL SOCIETY.

On April 30th at Londonderry, before the Ulster Branch, Lieut.-Colonel R. McCarrison, C.I.E. I.M.S., gave a British Medical Association Lecture on some problems of thyroid disease. On the following day a special meeting of the Ulster Medical Society was held at Belfast, with Dr. Singleton Darling in the chair, when Colonel McCarrison gave a lecture on some points observed during his researches on goitre and deficiency diseases during the last twenty years. The room was filled to overflowing and the address was followed with the greatest interest. At the end a hearty vote of thanks was passed with enthusiasm. Colonel McCarrison is an Ulster man, and received his medical education in Queen's College, Belfast; this is the first time his fellow countrymen have had an opportunity of showing their appreciation of his work. In the evening he was entertained by a few medical friends to dinner, but the notice was so short that many who desired sincerely to join in doing him honour were unable to be present.

#### A MEDICAL FAMILY.

Dr. William S. Boyd, assistant tuberculosis officer for County Down, has been unanimously elected medical officer of the Hillsborough Dispensary District, County Down, in succession to his father, the late Dr. Henry J. Boyd, who had held it for many years, and who had succeeded his father in the same post. The many friends of the late Dr. Boyd, whose death was noticed in our issue of April 11th, will be much pleased that he is followed by his son; the unanimous and enthusiastic election of Dr. William Boyd proves that the feeling of the public is one with that of the profession.

### Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

The House of Commons has this week completed the report stage of the Budget resolutions, taken the second reading of the Rating and Valuation Bill, and debated unemployment on the Ministry of Labour vote. Before the debate on the Rating Bill the Minister of Health met the Unionist Public Health Committee; Dr. Fremantle, who presided, explained that the Government meant to carry this bill into law this session, in order that Poor Law reform might be effected next session. It is recognized that to carry the Rating Bill the Government will have to ask Parliament to reassemble in the autumn to complete the business of 1925, and thereafter to hear the King's Speech before Christmas. The Public Health (Scotland) Amendment Bill was passed through Grand Committee on May 12th without amendment. A proposal by Mr. William Adamson to extend the operation of the bill to remedies other than insulin and diseases besides diabetes was ruled out of order.

The spokesmen of those osteopaths who desire Government recognition and statutory registration propose to arrange a deputation to the Minister of Health early next month, and are drafting a bill incorporating their demands. Mr. Basil Peto has tabled a series of questions to the Minister of Health asking for action in the same sense.

#### Small-pox and Vaccination.

Sir William Davison asked the Minister of Health the number of children in this country who were unprotected by vaccination and the percentage of babies for whom certificates of exemption were granted last year. The Minister replied that this information was not available, but the figures of exemption for 1922 were equal to 44.5 per cent. of the children born, the corresponding figure for children vaccinated being 40.5. Sir William Davison further asked what steps the Minister was taking to protect the country against an extension of the present outbreak of small-pox. Mr. Chamberlain replied that the responsibility rested on the local authorities and their officers, but the medical officers of the Ministry of Health were giving all possible assistance and advice to authorities of affected areas.

Sir William Davison asked whether the Minister would consider reimposing the regulation which had been withdrawn last year. Captain A. Evans asked what percentage of the objections were medical and what conscientious. No answer was given to either

question. In figures which were circulated later in reply to a question by Dr. Watts, Mr. Chamberlain stated that 849,069 children were born in 1921; 324,864 were vaccinated, and in respect of 382,157 children certificates of conscientious objection were received. In 1922 there were 780,277 births, 314,550 vaccinations, and certificates of conscientious objection in respect of 347,511 children. The Minister had no information as to the number of cases in which proceedings had been taken for the enforcement of the provisions of the Vaccination Acts during the same years.

Dr. Fremantle asked the number of cases and deaths from small-pox in the first four months of this and of the previous three years. In reply the Minister stated that in the first four months of 1922 there were 317 cases with 1 death; in the first four months of 1923, 692 cases with no death; in the first four months of 1921, 1,563 cases with 3 deaths; and in the same period of the present year there were 2,214 cases (provisional figures) with 3 deaths. Dr. Fremantle further asked the Minister of Health whether he proposed to rely on present methods of sanitary administration and of vaccination administration to check the further spread of the disease or to promote, and, if so, in what way, a fuller recourse to protection by vaccination. Mr. Chamberlain replied that he was carefully watching the course of the present outbreak of small-pox, but as at present advised he did not consider it at this time necessary or expedient to modify the existing administrative arrangements for dealing with small-pox. At present he did not think it necessary to issue any fresh regulations.

Colonel Day asked the Minister of Health, on May 12th, how many deaths had been registered during the half-year ending December last from small-pox, measles, pneumonia, scarlet fever, diphtheria, and influenza. Sir Kingsley Wood (Parliamentary Secretary to the Ministry of Health) replied that the figures for England and Wales were: small-pox, 3; measles, 1,517; pneumonia, 12,331; scarlet fever, 426; diphtheria, 1,205; and influenza, 2,145. In two of the cases classed as small-pox that disease was entered by the medical practitioner as a contributory cause of death.

**Patent Medicine Duties.**—In explanation of the financial resolution continuing the additional medicine duties, Mr. Gnuines (Secretary of the Treasury) said, during the report stage, that the original scales of medicine duty were permanent. They had been doubled in 1915, with the unexpected result of more than doubling the revenue from them, which for the nine subsequent years had been £1,089,000, against £329,000 for the nine previous years. The Treasury found that these increased duties had not affected the sale of patent medicines, and they did not impede the work of panel doctors, less than 1 per cent. of whose prescriptions were estimated to come under the operation of the duties. The Government regarded them as valuable duties, which imposed no hardship on any class. The resolution continuing the duties was then accepted without debate.

**"Headache Powders."**—Answering Colonel Day, on May 1th, the Minister of Health said that he was aware that so-called headache and nerve powders sold by small traders frequently contained acetanilide, a drug which, if improperly used, was likely to cause in the case of a young woman at se body a packet of a powder containing showed that an excessive dose had been taken deliberately. It was a matter of controversy whether acetanilide, though its action might be injurious, could be regarded as a poison in the ordinary sense. It did not come within the terms of the Dangerous Drugs Acts, and, pending legislation for the control of secret remedies, he doubted whether effective steps could be taken to restrict the sale of headache powders containing it.

**Morphine and Heroin Production.**—Answering Commander Kenworthy, on May 7th, the Home Secretary said that, according to provisional figures, two factories in Edinburgh, in 1921, manufactured 99,400 oz. of morphine, 16,700 oz. of heroin, and 153,300 oz. of codeine. The exports of morphine, including morphine in preparations made direct from raw opium, were 88,870 oz., and of heroin 10,704 oz. No statistics were available of the export of codeine, which was not a dangerous drug. Europe took 60,000 oz. of morphine and 7,600 oz. of heroin. The imports of raw opium for 1924 were 155,792 lb., of which the two morphine-manufacturing firms took 109,004 lb.

**National Health Insurance.**—The Minister of Health will consider whether the Royal Commission on National Health Insurance should issue an interim report. In 1913-21 the average number of weeks of sickness benefit paid to men under the National Insurance Act was 6,300,000, and to women 3,790,000. In 1923 it was 6,750,000 for men and 4,250,000 for women. In 1913-21 the average disablement benefit was 2,975,000 weeks for men and 1,550,000 for women. In 1923 it was 6,000,000 for men and 3,500,000 for women.

**Pensions.**—Mr. Windsor asked Major Tryon why, seeing that Supplementary Estimates for 1924-25 had provided £920,000 for treatment allowances in excess of pension, the estimates of the Ministry of Pensions for 1925-26 showed a reduction of £1,140,500 in the provision for treatment and treatment allowances. Major Tryon replied that only £430,000 had been voted as a Supplementary Estimate for treatment allowances. The reduction of the vote during the present financial year anticipated that the normal decline in the requirements for treatment would continue. Mr. Windsor further asked whether any instructions had been issued to the medical officers of the Ministry that they should, as far as possible, reduce the number of cases in which allowances were to be paid, even though the pensioner might be totally disabled temporarily as a result of his war disability. Major Tryon replied

that no instructions in this sense had been issued, and that no change had been made in the conditions of eligibility for treatment allowances. Major Tryon informed Mr. Roblson, on May 7th, that the Government was not considering proposals to terminate the Ministry of Pensions as a separate department in 1927 and to hand over its duties to the Ministry of Health.

**The Trevelth Report.**—Mr. Neville Chamberlain, in reply to Mr. Basil Peto, on May 7th, said the Ministry of Health had accepted the principal recommendations of the report of the Committee presided over by Lord Trevelth, and action was being taken to give effect to them. He was still in correspondence with the two societies interested in the combating and prevention of venereal disease with regard to the recommendation of the report referring to the sale of disinfectants by chemists. Mr. Peto further asked whether agreement between the two societies would be followed by legislation in the present session. Mr. Chamberlain said that did not depend on agreement between the societies, but he had been in correspondence with them.

**General Nursing Council.**—The Minister of Health is prepared to recommend the appointment of a Select Committee to examine the revised scheme for the election of nurse members of the General Nursing Council, and to report whether the adoption of the Council's syllabus of training should be compulsory. Our Parliamentary correspondent adds that the Government is proceeding with the setting up of this Select Committee, of which Major Barnett will be chairman. Mr. H. A. L. Fisher and possibly Dr. Fremantle are to be members of it.

**Pollution of Water Supplies.**—In reply to Dr. Fremantle, Mr. Neville Chamberlain said before considering legislation for safeguarding supplies of underground water and preventing its pollution, as proposed by the Advisory Committee on Water, he must consider the views of the interests affected. These views would be available at an early date, but he did not think the legislation could be carried through this year.

**Unemployment and Health.**—The Minister of Health, on May 12th, informed Mr. Groves that the figures for certain districts with the highest average degree of unemployment for the twelve months ended February last indicated that in the majority of those districts the birth rate and the infant mortality for 1924, and the percentage of population living more than two persons to a room, according to the census returns for 1921, were above the average for England. There was not, however, sufficient correspondence between the figures to warrant any general conclusion. The Government was exploring all possible means of reducing unemployment, overcrowding, and infant mortality.

#### Notes in Brief.

The Minister of Health hopes to introduce legislation dealing with the reconstitution of the registration service for births, marriages, and deaths.

The proposed improvements in the ventilation of the House of Commons will not be made before the autumn recess.

The Bombay Government has adopted a declaration of the Bombay Excise Committee that the extinction of the traffic in alcoholic liquor and drugs by suitable steps should be the goal of its excise policy.

A smoke abatement bill is proposed for next year.

The Home Secretary has not reached any decision on the inclusion of bursitis with miner's heat-knee in the schedule of industrial diseases.

The Home Secretary cannot say when the Factories Bill will be introduced. It is quite impossible to give a pledge to pass the bill this session.

According to the latest returns there are 36,518 blind persons in England and Wales, of whom 12,024 between the ages of 50 and 70 receive the old age pension. Of the blind population over school age, 20,759 are returned as unemployable and 8,234 as employed. In workhouses and workhouse infirmaries there are 3,000 blind.

The Minister for Education is considering, in consultation with the local authorities, the whole question of the provision of special schools for blind, deaf, physically and mentally defective, and epileptic children.

The Minister of Health will fix the date of operation of the regulations on preservatives in food so as to allow time for the disposal of existing stocks.

The Home Secretary informed Colonel Day, on May 7th, that it was impracticable to issue an order for the compulsory sterilization of hides, as no effective method was known which did not seriously damage them for commercial purposes. The Chief Inspector of Factories stated that the existing statutory precautions under the Hides and Skins Regulations were in general well observed. Two recent cases of anthrax in the Southwark area were not due to any breach of the regulations.

The Ministry of Labour calculates that about 137,700 young women between 16 and 30 are drawing unemployment benefit.

A school dental service has not been started by the education authorities of 12 counties, 4 county boroughs, 21 boroughs, and 11 urban districts. Fourteen of these have made proposals for dental schemes.

The Therapeutic Substances Bill was down for second reading on May 11th, but was again postponed.

In 1914 8,834 children in England and Wales were classed by local authorities as suffering from some form of tuberculosis but as attending no recognized school or institution.

## Correspondence.

### SLEEPLESSNESS IN ENCEPHALITIS.

SIR,—Dr. C. P. Symonds in his interesting paper on sleep and sleeplessness, in the *British Medical Journal* of May 9th (p. 870), definitely classifies the insomnias of the chronic stage of encephalitis as due to disease directly involving the sleep centre (if there is one). My own experience in Ruchill Fever Hospital showed that the capacity for sleep was not in any case impaired, although the time was altered.

In a small ward were seven boys who had passed through the acute stage of encephalitis two or three months previously. Their ages varied from 4 to 14 years, and they all suffered from nocturnal restlessness associated with ties, such as nose-tugging, "trumpeting," sniffing, etc.

I determined to try the effect of turning their night into day. Accordingly they were put to bed at 6 a.m. and made to rise at 6 p.m. for breakfast. Dinner was served about 11 p.m., tea at 3 a.m., and supper about 5 a.m. They were told that they were on "night duty," and were allowed to read or play about the ward. For the first few nights they kept awake with difficulty until 6 a.m., but the new rhythm was soon established. They had no difficulty in falling asleep. All day they slept soundly till 4 or 5 p.m. In a short time they showed a distinct general improvement. They put on weight, and their faces lost the tired or excited expression. The ties diminished in frequency, but did not disappear.

After five weeks of this treatment I tried reversing the periodicity back to normal. Accordingly one morning the boys were told that they did not require to go to bed until they liked. Next morning they were roused at 6 a.m. For seven to fourteen days (varying in different cases) they slept well at night, but the old night restlessness returned along with an increase in the ties. Their hours of sleep were diminished. By again turning night into day improvement again resulted.

I concluded that the treatment was in no sense a cure, but by securing an adequate sleep must tend to assist natural recuperation. It certainly diminished excitability. Unfortunately conditions prevented me from continuing the experiment for a further period. It would have been interesting to see if a "morning restlessness" finally resulted.—I am, etc.,

JAMES L. HALLIDAY, M.D.

Public Health Department, Glasgow,  
May 12th.

### THE MORTALITY OF APPENDICITIS.

SIR,—The post-operative mortality of appendicitis is still very large and has shown no diminution during the past decade.

It is generally admitted that: (1) Operations performed during the first twenty-four hours of an acute attack have a mortality of less than 1 per cent. (2) In cases of local peritoneal infection the death rate is highest when the operation is performed from the third to the fifth or sixth day (10 per cent. or more). (3) If, in cases of local infection, an operation is performed during the second week (opening and draining an abscess), the mortality rate is much lower. (4) Cases where there is general peritoneal infection have a higher death rate, although owing to improved methods—that is, pelvic drainage, Fowler position, etc.—this is far lower than it used to be fifteen or twenty years ago.

It is generally agreed that an operation should always, if possible, be performed during the first twenty-four hours after the onset, and that in all cases where the general peritoneal cavity is involved operations should be performed without delay, the appendix removed, and the pelvis drained.

There is considerable difference of opinion as to the advisability of operating during the dangerous period when the infection is local—that is, from the third to the sixth day. Some surgeons advocate delay till after the

first week, others operate at any time that the case presents itself.

Why is it safe, or almost safe, to remove an inflamed appendix during the first twenty-four hours and dangerous to perform the same operation from the third to the fifth day, when the inflammation has spread to the neighbouring peritoneal surfaces, and a local abscess has formed? The explanation is that in operating upon an early case, while infection is confined to the appendix, it is generally possible to remove the appendix by cutting through healthy uninfected tissue at its base; in this case there is no more danger than in performing an interval operation or removing a normal appendix. But when infection has involved the neighbouring peritoneum, caecum, etc., it may be necessary, in removing the appendix, to cut through or crush tissue infected with virulent organisms—the *Bacillus coli* and *Streptococcus faecalis*—and so drive these organisms into the blood stream, setting up an acute septicaemia or bacillaemia, after an incubation period of twenty-four to forty-eight hours; and even handling inflamed tissue or removing the protective layer of lymph from the abscess wall may give rise to the same infection.

The symptoms of this septicaemic infection are very evident, especially in children. A sudden change for the worse in the facial aspect occurs, the pulse rate increases, and pallor of the face, restlessness, followed by delirium and dilatation of the pupils, develop. A shrill "meningeal" cry is very noticeable, and death, preceded by coma, follows within twenty-four hours of the onset of serious symptoms. Some of these deaths have been attributed to delayed chloroform poisoning. I have seen a good many such cases during the past fifteen years, and in every instance in which I have made a culture from the blood during life, after the onset of the symptoms, there has been an abundant growth of the *Streptococcus faecalis* or *Bacillus coli*; in most cases the *Streptococcus faecalis* was the organism present. In no case of appendicitis in which these symptoms have not appeared have I been able to find any blood infection.

When patients are operated upon after the first week, sufficient toxins have been absorbed into the circulation to produce a considerable degree of immunity to infection owing to the development of antibodies; hence the diminution of mortality after the first week.

When there is general peritoneal infection the danger to life is due to toxin absorption and bowel paralysis, and operation is imperative at any stage of the disease. —I am, etc.,

HERBERT H. BROWN, M.D., F.R.C.S.

Ipswich, May 4th.

#### RELAPSE IN MEASLES.

Sir,—In further reply to "G.P.'s" question, "Is there such a thing as a relapse in measles?" (*BRITISH MEDICAL JOURNAL*, May 9th, 1925, p. 908), I answer in the affirmative.

One of the best modern authorities on infectious diseases, the late Dr. Claude B. Ker of Edinburgh, whose death from pneumonia so recently as March 25th of the present year we all deplore, wrote in his standard work:

"Relapse of measles is exceedingly rare. I have seen one case, however, in which a typical attack was followed seven or eight days later by a repetition of the disease with equally classical symptoms. Neither attack was in the least like rubella. The patient, a young female adult from the Highlands, made a good recovery."

Describing measles in my *Eruptive and Continued Fevers* many years ago, I wrote:

"In rare cases a relapse of the eruption has been known to occur with a return of the fever movement also. In these cases, according to Thomas [of Leipzig], the spots appear on parts of the skin previously uninvaded by the exanthem. These relapses are of short duration."

In thirteen years' practice at Cork Street Fever Hospital I met with no case of relapse, a fact which testifies to the rarity of the condition.

In the *Deutsche medizinische Wochenschrift* (December 3rd, 1892) Dr. W. Streng reports from the medical clinic at Leipzig a case of relapse in measles in a little girl aged 6 years. On the tenth day after the eruption the temperature began to rise gradually to 103.8°, and on the twelfth

day a measly rash appeared for the second time, corresponding with the highest temperature, accompanied by a recrudescence of the catarrhal symptoms, and attaining its greatest intensity the following day. During the night between the fourteenth and fifteenth days after the first eruption a critical fall of temperature occurred, while the rash faded gradually during the next two days.

In a *Treatise on the Acute Infectious Exanthemata* Professor William T. Corlett of the Western Reserve University, Cleveland, U.S.A., mentions that he saw a case of relapse in measles in consultation. In that instance there was an interval of eight days between the subsidence of the eruption and the second efflorescence. In both attacks the usual symptoms were present, although the exanthem was most marked in the second. He looked upon the case as one of recurrent measles such as was described by Trojanowsky (*Dorpat. med. Zeitung*, 1873, iii), but he quotes several authors who had observed cases of relapse occurring most frequently about the end of the second week, accompanied by a return of the fever and, to a less extent, of other constitutional symptoms.—I am, etc.,

Dublin, May 9th.

JONX W. MOORE, M.D., F.R.C.P.I.

#### NODAL FEVER.

Sir,—A number of years ago I treated a case beginning as erythema nodosum, which certainly suggested that this disease should rank as a specific infective fever, and the modern name, "nodal fever," seems quite fitting.

The patient was a middle-aged lady on a visit to friends. The illness began with typical nodes on the shins without any marked prodromata. Strict rest was enjoined, with protection of the legs, and salicylate was given internally. All went well for a time and then dry pleurisy came on, later pericarditis and endocarditis, as evidenced by the physical signs. At the same time signs of pneumonia of a fleeting nature were present—distant tubular breathing, quite distinct—in one place one day, in another the day following.

As the patient's condition was not satisfactory a very distinguished consultant, who knew the family, kindly came from the North and gave me the benefit of his advice. Unfortunately no improvement took place, and the patient eventually died with well marked symptoms of meningitis. At various times there was a considerable amount of "rheumatic" pain in the limbs.

Here was a marked case of polyserositis—or, as it was more comprehensively, perhaps more accurately, but less gracefully, called then, polyarthromenitis—following erythema nodosum.—I am, etc.,

Oxford, April 22nd.

F. G. GARDNER.

#### TREATMENT OF DIABETES BY RAW, FRESH GLAND (PANCREAS).

Sir,—On my return, a few days ago, from a trip abroad my attention was called to the letter on the above subject by Dr. Harrison published in the *BRITISH MEDICAL JOURNAL* on April 18th (p. 760). Dr. Harrison is guilty of an inaccuracy when he states that he repeated the experiments of Dr. Young and myself, for our cases were treated by raw gland from the beginning and never had any insulin. This also applies to the letter of Dr. Graham (May 2nd, p. 859).

The result obtained by Dr. Harrison from his experiments is just what I should have expected, as, for some reason which I am at a loss to explain, cases that have been treated with insulin do not seem to respond at all when raw gland is substituted, or, apparently, when raw gland is given in conjunction with insulin. This is a matter which I am at present investigating, and had intended referring to at a later date. One case, a lady, who was sugar-free on 1½ oz. of raw gland, went on to a course of insulin for some months, and on resuming gland treatment again became glycosuric at once.

Dr. Harrison suggests that any improvement from gland treatment is really due to altered diet. A glance at my article will show that he is wrong. The first case recorded by me had been most carefully dieted for some months both by me personally and at the local hospital, and notwith-

standing the "alteration in diet" he became steadily worse. When, however, raw gland was added to this diet he began to improve at once. As further proof that alteration in diet alone cannot account for the extraordinary success obtained in some cases, I have only to refer to the case recorded by Dr. Dunn (*BRITISH MEDICAL JOURNAL*, April 4th, p. 680). This case too, it must be remembered, was a member of a diabetic family, and could only tolerate a very limited amount of starchy food before starting gland treatment, but shortly after being put on raw gland he was able to take "full diet." I may say in conclusion that I welcome the destructive criticism of Dr. Harrison and others, and am anxious that this treatment may be subjected to the most rigid and carefully controlled tests, as my object in writing was to call the attention of the profession to a form of treatment which I firmly believe to be of very real value in many cases, possibly in all cases, of diabetes.—I am, etc.,

Sandwich, Kent, May 5th.

THOMAS J. HOLLINS.

## THE DECLINE OF LITHOLAPAXY.

SIR,—We have been much interested in the article on "The decline of litholapaxy" by Major-General Hooton in the *JOURNAL* of April 11th (p. 690), and the letter by Mr. Southam the following week.

I think it is fairly evident that this operation is much more common abroad than at home. In the Church Missionary Society's Hospital in Old Cairo we have a good many cases of vesical calculus, and though our figures cannot touch those of Hyderabad yet they compare well with the others mentioned.

In the last ten years (the period mentioned for the English hospitals in Mr. Southam's letter) 636 cases of vesical calculus were treated here. The operation was litholapaxy in 424 cases and suprapubic cystotomy in 212. Formerly perineal cystotomy was performed in preference to the cutting operation, but during the above period this operation has only been done very occasionally, the suprapubic route nearly always being chosen. It will be seen that while the proportion of crushing to cutting is not nearly so frequent here as it is in India, yet it is much more frequent than in any of the English hospitals. The crushing operation is always chosen unless there is some contra-indication; but we do consider it a dangerous operation in this country except in experienced hands. This is due to the great proportion of cases where stone is associated with bilharziasis of the bladder, which condition causes weakness of the bladder walls, with consequent risk of rupture and papillomatous growths on the lining mucous membrane which may easily be injured.

We find that the routine use of spinal anaesthesia by stavaine makes the operation of litholapaxy much easier than when a general anaesthetic is used.—I am, etc.,

ROBERT B. COLEMAN,  
Church Missionary Society's Hospital,  
Old Cairo, Egypt.

May 2nd.

## RECENT ADVANCES IN THE STUDY OF CARDIO-VASCULAR DISEASE.

SIR,—In your issue of May 2nd (p. 859) Professor MacIlwaine kindly referred to my work on the venous pulse. May I take advantage of the occasion to draw the attention of your readers to the fact that the optical method of recording reveals a sharp-pointed oscillation on the v wave which is not revealed by any lever system, though a small corresponding notch or two may be seen in a delicate lever record in certain types of pulse. The different types of venous pulse met with in health formed the subject of a verbal communication at the December meeting of the Physiological Society, when it was suggested that this v oscillation, useful marking point of the onset of diastole, may, by its relationship to the point of opening of the a-v valves, reveal varying time relations for the process of venous return. The causation, time of occurrence, etc., of this new element are discussed in my original paper (*Journ. of Physiol.*, lix, 1924, p. 293).—I am, etc.,

Physiological Department, University College,  
Cork, May 4th.

D. T. BARRY.

SIR,—The courteous letter of Professor MacIlwaine (*BRITISH MEDICAL JOURNAL*, May 2nd, p. 859), for which I thank him, demands a few words from me.

To my regret he does not deal with the specific objections to the current interpretation of the venous tracing which I have put forward; I had hoped for his comments upon them. He alludes to Professor Barry's recent work upon the v wave (*Journ. of Physiol.*, vol. lix, p. 293), which certainly does draw attention to the conflict of opinion obtaining as to this wave—I am indebted to Dr. MacIlwaine for this reference—but as it does not bear in any way upon my criticisms of the wave, I need not consider it here.

I have questioned whether, among modern instrumental methods, the polygraph has led to a real advance in the study of cardio-vascular disease; hereupon Dr. MacIlwaine comments: "I am afraid this must remain a matter of opinion." Surely this is the one thing which is not possible if medicine is to make any claim to be a science.—I am, etc.,

Swanage, May 11th.

HARRINGTON SAINSBURY.

## SLOW HEART.

SIR,—Dr. Lloyd's letter (May 2nd, p. 860) induces me to state that my pulse rate is 55 at rest and 59 to 60 for moderate activity. My attention was first called to the fact when, just over twelve years ago, at the age of 27, I began to study medicine. At the end of 1912 I suffered from a mild form of neurasthenia, and I found I had an intermittent pulse. Between 1913 and 1916 I was examined several times and cardiac arrhythmia of the extra-systole variety was diagnosed, but the cause was not so easy to find, as there was no history of dyspepsia and I have always been a non-smoker and abstainer. The only thing to explain the condition seemed to be the antecedent neurasthenia. I had been a keen athlete until I was 25—long-distance swimmer, gymnast, cyclist, and in the habit of rowing long distances, and no doubt the effect of primary cardiac overstrain had, and still has, something to say to my condition. My pulse, which was intermittent until 1920, has since been regular, but the average rate of about 56 has not at all altered in the last five years. It is well known that the pulse rate in active animals—for example, the horse and dog—often diminishes in old age, and the same thing is true of the human pulse; but is it not curious that the pulse rate of a racehorse should be 40 to 45 but that of a dog 90 to 100? Is not the faster rate more what we should expect with rapidity of motion?

During the last five or six years I have been keenly interested in the pulse, and have met quite a number of instances of the slow variety. The members of my family have normal pulses, so I think I must have started life with a normal one.—I am, etc.,

Wallasey, May 9th.

BAUCE BRIGGS (CLK.), M.B.

## OSTEOPATHY AND CHIROPRACTIC.

SIR,—Your article headed "Osteopathy and Chiropractic" in the *BRITISH MEDICAL JOURNAL* of April 11th (p. 706), in which you have coupled with my name a criticism of osteopathy and a serious attack on American medical education, chafes me to reply.

"The conditions," as you state, "are not the same in the two countries." In the British Isles no university, college, or medical school is empowered to grant a degree unless the standard of teaching and professional examinations meets the requirements laid down by the General Medical Council. British medical degrees are, therefore, more or less uniform, and the possessor of a British medical degree is admitted without further examination to the *Medical Register*. In the United States of America a medical degree from a university or medical college does not automatically confer a licence to practise. Each State in America prescribes and conducts its own State Board examinations. Even a Harvard medical graduate has to pass a State Board examination before he can obtain a licence to practise.

The American colleges of osteopathy did not introduce such subjects as bacteriology and surgery into their curricula in order (as you imply) to become assimilated to orthodox medicine, but in order that their graduates might be knowledgeable, might be able to make a complete diagnosis and refer cases to the surgeon when necessary, might be able to pass State Board examinations and obtain a full licence to practise.

You suggest that in this country "the type of diploma appropriate to them [the osteopaths] is the medical diploma and nothing less. They should take it before receiving a licence to practise." I would point out that in the British Isles no one need take a licence to practise anything except medicine and surgery. The osteopaths are not asking for a licence to practise medicine or surgery.

It is obvious, when you convey the impression that osteopaths ask you to "believe that a cold in the head, a crop of pimples on the face, an attack of vomiting and diarrhoea after a gorge, an attack of gout or measles . . . are, one and all, due to small spinal irregularities which may be readily corrected by manipulation of the back," that your conception of osteopathy is founded on the views and practices of the very osteopathic charlatans from whom the British Osteopathic Association is anxious to protect the public. Qualified osteopaths do claim that spinal column abnormalities not hitherto detected by the medical profession do exist, and that such framework abnormalities cause a lowering of local or general resistance, thereby allowing other etiological factors in disease, such as organisms, etc., to exert their influence unduly.

You say "our osteopathic visitors will have to fall in with our ways." In reply, your qualified osteopathic visitors are trying to fall in with your ways. They realize that they can continue, unheeded by the law of the land, to practise—as they very successfully do—their art, but they are anxious that the British public should have some means (to use your words) of distinguishing the sheep from the goats. They ask for an official register of qualified osteopaths in Britain, and they ask for a charter for the British school of osteopathy in order that their diploma may be of more value than the paper it is written upon.—I am, etc.,

Edinburgh, April 28th.

W. KELMAN MACDONALD, M.D.

#### APPENDICITIS.

SIR,—In reply to the letter from Dr. T. A. Black in the *JOURNAL* of May 9th (p. 904):

In my experience the sudden onset is due to obstruction and distension of the appendix, the gradual to inflammation without these conditions. It is impossible to predict the course of any case of appendicitis at its onset, therefore whether the attack be sudden or gradual the only safe procedure is to terminate it by early removal of the appendix.—I am, etc.,

London, W 1, May 9th.

JAMES SHERREN.

#### CENTRAL MIDWIVES BOARD INQUIRY.

SIR,—In the article on puerperal sepsis in the *BRITISH MEDICAL JOURNAL* for May 9th I observe that it is stated that the Central Midwives Board contemplates an inquiry into the matter through the agency of the local authorities.

This statement is not accurate. The Board is proposing that a conference between members of the Board and representatives of local supervising authorities shall be held with the object of bringing into closer touch the authorities specifically charged with the administration of the Midwives Acts—namely, the Central Midwives Board and the various local supervising authorities in England and Wales—with a view to more efficient administration, if possible, of those Acts.

It is not proposed that the conference shall deal specially with puerperal sepsis, the object of the conference being general, as above explained.—I am, etc.,

Central Midwives Board, May 11th.

H. G. WESTLEY,

Secretary.

## Medico-Legal.

### A CASE OF MALINGERING.

A CASE of much medical interest was heard in the County Court at Doncaster on April 22nd. In summing up, his Honour Judge Turner spoke of it as the most clearly proved case of malingering that had come before him, and awarded costs on the highest scale against the workman claiming compensation. The facts were briefly as follows.

A. B., aged 45, a builder's labourer, on January 4th, 1922, was breaking a slate, when a piece of the slate struck his left eye, causing a wound of the lower third of the cornea, with entanglement of iris and lodgement of small fragments of slate in the anterior chamber. Compensation had been paid by the employers, who were now applying for the termination or diminution of the weekly payments, on the ground that the workman was capable of resuming his original employment. The man's counsel contended that he was now in the position of a one-eyed man. On the other side it was contended that he was malingering and had good vision still in both eyes.

Mr. G. H. Pooley, F.R.C.S., ophthalmic surgeon to the Royal Infirmary, Sheffield, stated in evidence that the man had been a patient under his care at the infirmary. Iridectomy was done on January 13th, 1922; a piece of slate in the anterior chamber was removed (by washing out). The lens was not injured. Twelve months later the vision in each eye was 6/9 without glasses. In August, 1923, the man's vision in the injured eye was said to be less than 6/60, the vision in the right eye being still 6/9. In November, 1923, there was redness of both eyes, and at the suggestion of Mr. Whitehead of Leeds a small particle was removed from the anterior chamber which might possibly have been a small foreign body, or possibly consisted of exudate. Though the eyes were red at that time there was no sign of iritis or deep-seated inflammation. Three months later (February, 1924) vision in the right eye was stated to be 6/24, and no perception of light was admitted in the injured eye. Both pupils reacted well. Both eyes showed superficial redness, but no sign of any deep-seated inflammation. "I then formed the suspicion of malingering," Mr. Pooley continued, "because I could find no cause for this surface redness. He could have induced it by rubbing. If the left eye was as bad as he made it out to be it would have been my duty to remove that eye. If it was as good as I thought, then it was my duty to leave it in. I could never find any sign of internal inflammation, and I could find no reason why vision of either eye should have fallen below what it was in January, 1923 (6/9 in each eye). He asked me to remove the eye. He was admitted to the Royal Infirmary again in August, 1924, to be under observation. The eyes were both superficially red, but there was no sign of any internal inflammation. There was no iritis, no irido-cyclitis. From observations in hospital I satisfied myself that the redness was due to self-inflicted injury—namely, rubbing. We put blistering fluid on the outer surface of his lower eyelids, so that he could not rub the eyes. The eyes quieted, the redness was gone, while this was on." Subsequently, the redness having returned, each eye was covered with a watch-glass and adhesive plaster, and again the redness disappeared for a time. "I came to the conclusion that he had good working sight in both eyes, and that there was no need to remove the left eye." On April 16th, 1925 (six days before the case was heard in court), the man was examined again, at Mr. Pooley's consulting rooms, his house-surgeon, Mr. Nutt, being also present. On this occasion, on his vision being tested, the man would only admit bare perception of light in the right eye—the uninjured eye. "He told me he could not see a bright light at six yards with his right eye. He could not count my fingers. When a light was thrown in his right eye from a mirror he said he could just see that. He would admit no perception of light in the left eye. Both pupils reacted normally to light." Both eyes were perfectly healthy in appearance except for the scar in the lower part of the left cornea and the gap in the iris left by the iridectomy, and some superficial redness of the lower part of the white of both eyes, similar to that seen on previous occasions. About five minutes later the man admitted that he could see 10 mm. squares of red and green at about a foot distance. This showed he must have much better vision than he had admitted a few minutes before. Later on he saw 6/24 with the right eye, and then saw 6/24 with the left eye. This observation was obtained by placing a +3 D. lens in front of the right eye and leaving the left uncovered, when he read 6/24. It was subsequently demonstrated that with the +3 D. lens in front of the right eye, that eye could read barely 6/60. "At the end of the interview he pulled out his watch and read the time accurately. In my opinion he has perfectly good sight in both eyes."

Mr. A. B. Nutt, M.B., Ch.B., ophthalmic house-surgeon at the Royal Infirmary, Sheffield, confirmed Mr. Pooley's evidence as to the examination at his consulting room on April 16th, 1925, and also as to the observations made in hospital in the preceding August. He gave evidence of a further test which he had made, at which Mr. Pooley was not present. "I seated the man in a small ante-room, and put goggles set in plaster on to both eyes. The right glass was opaque, the left glass clear. He would not be able to see anything with the right eye. I seated him with the door on his immediate right hand, so that he could not see if he was being observed through the door unless he turned right round and faced the door with his left eye. I watched him, and he remained quite still for about five minutes, after which he turned round and faced the door with his left eye." He repeated this after another five minutes' interval.

Mr. A. L. Whitehead, F.R.C.S., senior ophthalmic surgeon to the Leeds Infirmary, said he had examined the man in February, 1923, when the right eye was quite normal and the vision of the left eye 6/24; there was a ragged scar across the lower third of the cornea. He examined the man in February, 1924, when the vision of the left eye was said to be no perception of light. "I tested him with a prism and came to the conclusion that he had considerably better vision than he stated. I was in considerable difficulty because the man struck me as being an honest and truthful man, but I could not find anything in the condition of his eye to account for so marked a deterioration of vision as from 6/24 to no perception of light. I thought that he should have had about 6/60 vision in that eye." Asked if he accepted Mr. Pooley's test (as to the vision of the left eye), Mr. Whitehead replied that he did accept it. In February, 1924, he found that the injured eye was congested over the lower portion. "This redness did not subside after an interval of half an hour as it would have done if produced by rubbing, but was markedly increased and spread over the whole eye after exposure of the eye to a bright light and the manipulation of the eye necessary for testing it. That indicates that the eye is not perfectly sound, and work exposing it to dust and other irritating influences is unsuitable." In reply to a remark by the judge that this would exclude most kinds of work for such a man, Mr. Whitehead said he was referring more especially to irritating dust such as lime dust. In cross-examination, he stated that he had not found signs of iritis or keratitis punctata in this case, and that, apart from another injury, there was no likelihood of sympathetic disease being set up.

A. B., the injured workman, stated in his evidence that he could not see at all out of his left eye, that the right eye had been "rather damaged from the left eye," that since the injury he had had pains in the head and both eyes and been very dizzy. "It prevents me doing any work. I am afraid of falling over. Any time I might fall over."

The judge was assisted on the bench by Mr. Herbert Caiger, F.R.C.S. (Sheffield), as medical assessor. In giving his verdict in favour of the employers, the judge said that he had been able to form his own opinion as to the credibility of the man's statements by what he had himself just said in the witness-box. Malingering had been proved in this case more completely than usual.

Judgement was given in favour of employers with costs on scale C.

This case deserves the attention of all ophthalmic surgeons engaged in work connected with the Workmen's Compensation Act.

## Obituary.

THE death took place recently of Dr. CHARLES ALFRED RAYNE of Lancaster at the age of 79 years. He was a native of Kendal, and received his medical education at University College, London. He graduated M.B., B.S. Lond. with honours in 1873, and M.D. in 1887; he also took the diploma of M.R.C.S. Eng. in 1873. After serving as clinical and pathological demonstrator at the University of Oxford, resident physician to the Radcliffe Infirmary, Oxford, and assistant physician to the Children's Hospital, Manchester, he succeeded in 1881 the late Dr. Moore in practice at Lancaster. For thirty-two years he served as honorary medical officer to the Royal Lancaster Infirmary, of which institution he was consulting physician at the time of his death. Dr. Rayne, who was unmarried, had been in indifferent health for some time.

Dr. JOHN HENRY HERBERT PEARSON, who died on April 30th, in his 40th year, was a son of the minister of Newhaven, a suburb of Edinburgh. He graduated M.B., Ch.B. in the University of Edinburgh in 1908 and M.D. in 1913. After doing post-graduate work in the Royal Infirmary as clinical assistant in various departments, he began general practice from his father's manse. He got on well; with an inborn love of medical study and work he devoted himself to the care of his patients. Later he took a house and soon had an important practice. At the outbreak of the war he volunteered for service, and later was sent to Gallipoli, where in 1915 he contracted dysentery. He was sent home from the East, but went to France in 1916, where he was awarded the Belgian Croix de Guerre and the Order of Leopold, and was severely wounded. His long illness, pernicious anaemia, showed to those around him the full beauty of his character. At intervals hope was revived by temporary improvements in his condition, and he worked again amongst his patients and fished in his spare time. But with one of the relapses it became clear that his work was over, and the house and practice were disposed of. For eighteen months after that he lived, so ill at times that it seemed as if he could not last an hour; but now and

then better to the extent of getting out of bed and even, once or twice, of going for a little time into the country. Through all these alternations of hope and disappointment he remained cheerful and uncomplaining. He leaves a widow and a son and daughter.

We regret to record the death, on May 4th, of Miss GWYN YFOULKES ROBERTS, M.B., Ch.B. Liverp., in her 28th year. She had only a few weeks taken up her duties as one of the house-surgeons at the Royal Liverpool Children's Hospital when she contracted scarlet fever from a case admitted in error to her ward, and succumbed to a malignant attack to which she offered little resistance. It is inevitable in a children's hospital that the incidence of infectious disease among the unprotected members of the nursing and junior medical staffs should be high. It is tragic when infection results in the cutting short of a young and promising life and the termination of a career upon its threshold. As a student at Liverpool University and at the hospital where she became resident, Miss Roberts had given much promise of success in her profession. Her work was done with meticulous care and self-sacrifice; her disposition endeared her to all. She was the only daughter of Dr. J. W. Roberts of Knayton, Yorkshire, who died suddenly a few months ago; and much sympathy is felt with her widowed mother and her only brother, also a member of the medical profession.

The deaths are recorded of Professor P. FRIEDRICH, formerly professor of oto-rhino-laryngology at Kiel; Professor F. SCURFFENS, president of the Belgian Society of Oto-rhino-laryngology; and Dr. ALBERT MAHAUX, professor of psychiatry at Lausanne.

## The Services.

### ROYAL NAVAL MEDICAL SERVICE.

SURGEON VICE-ADMIRAL J. CHAMBERS, C.B., C.M.G., Director-General, Medical Department, R.N., has been appointed Honorary Physician to the King in succession to Surgeon Vice-Admiral Sir Arthur W. May, K.C.B., K.H.P., deceased.

The Royal Naval Volunteer Reserve Officers' Decoration has been awarded to Surgeon Commander H. L. Murray.

### DEATHS IN THE SERVICES.

Brigade Surgeon Patrick Walter Stafford, R.A.M.C. (ret.), died at Wimbledon on April 14th, aged 87. He was born in Wexford, and, after taking the L.K.Q.C.P. and the M.R.C.S. in 1859, entered the army as assistant surgeon in January, 1860. He became surgeon major in 1875, and retired, with a step of honorary rank, in 1885. As a regimental officer he served in the 56th Foot, now the 2nd battalion of the Essex regiment. During the Ashanti war of 1873-74 he was present at the battle of Amoaful, and received the medal with a clasp; in the Zulu war of 1879 he took part in the battle of Ulundi, was mentioned in dispatches, and received the medal with a clasp.

Brigade Surgeon William Edmondson Dudley, R.A.M.C. (ret.), died at Bath on April 13th, aged 86. He was educated in the school of the Royal College of Surgeons in Ireland, took the L.A.H. and L.R.C.S.I. in 1862, and the L.R.C.S. Ed. in 1863, and entered the army as assistant surgeon in April, 1863. In the old regimental days he served for five years in the 76th Foot, now the 2nd battalion of the Duke of Wellington's West Riding regiment. He became surgeon major in 1876, and retired, with a step of honorary rank, in 1884. He served in the Zulu war of 1879 with the 3rd Foot, the Buffs, and received the medal with a clasp.

Lieut.-Colonel Joseph Andrew Gormley, R.A.M.C. (ret.), died at Bournemouth on March 1st, aged 76. He graduated M.D. and M.Ch. (Queen's University, Ireland) in 1873, and entered the army as surgeon in the following year. He became surgeon lieutenant-colonel after twenty years' service, and retired on June 3rd, 1903. He had seen a great deal of war service: Perak campaign, 1875-76, medal with star; Afghanistan, 1878-80, medal; Sudan, 1884-85, Nile campaign, medal with clasp, and Khedive's bronze star; South Africa, Matabele campaign of 1896, as principal medical officer, mentioned in dispatches, *London Gazette*, March, 1897, and specially promoted to brigade surgeon lieutenant-colonel; and South Africa, 1899-1902, as principal medical officer of a division and of a general hospital, operations in the Orange Free State, actions at Paardeberg, Poplar Grove, Kamee Siding, Vet River, and Zand River, operations in Transvaal at Queen's medal with three clasps and clasps. After his retirement he was Thames from August, 1903, to April, recent great war.

## Universities and Colleges.

## UNIVERSITY OF OXFORD.

## Fellowship in Physiology at New College.

THE College proposes to elect, not later than October next, to a Fellowship in Physiology. The person elected will be required to undertake, as from Michaelmas term next, the teaching of members of the College reading for the Honour School of Physiology and the medical examinations. Details of the appointment and forms of application can be obtained from the Warden. These forms, duly completed, should be returned to the Warden not later than June 15th.

## UNIVERSITY OF CAMBRIDGE.

At a congregation held on May 9th the following medical degrees were conferred:

M.B., B.Chir.—J. H. Doggart, N. F. Adeney, J. Ness-Walker, A. S. H. Walford.

The Raymond Horton-Smith Prize, awarded to the candidate who presents the best thesis for the M.D. degree during the academical year, has been awarded to M. B. R. Swann (Caius); *proxime accessit*, D. V. Pickering (Emmanuel).

## Diploma in Psychological Medicine.

An examination for Part II of the Cambridge Diploma in Psychological Medicine will be held in London on June 10th, 11th, and 12th. Applications should be addressed to "The Registry, Cambridge University," at once.

## UNIVERSITY OF LONDON.

## DEGREE CEREMONY.

The annual degree ceremony of the University of London was held in the Albert Hall on May 13th.

## The Principal's Annual Report.

The Principal, Sir Cooper Perry, reported that the total number of those who had entered the University during the academic year 1924-25 was 7,605, as compared with 3,852 in the last year before the war and 7,751 in 1923. Of the total in the past year 5,542 came in through the ordinary matriculation examination, 360 as graduates of other universities, 998 as holders of the Oxford or Cambridge School Examination certificate, 483 as holders of other approved certificates, and 220 after examination under Statute 116, which authorizes the admission of a student after a special test. The total number of candidates for all examinations was 31,625, about 200 fewer than in the last year. Of the 3,420 candidates for degrees, 2,079 were internal and 1,341 external, figures which corresponded very nearly with those for the previous year. The number of candidates at all examinations who obtained diplomas and degrees was 2,642, as compared with 2,598 last year. The number of internal students had risen from 8,649 to 9,002.

The Principal enumerated various gifts made to institutions of the University, and mentioned that over 10,000 volumes had been added to the University library. The inspection of the various schools of the University had been continued, and through the reports of the inspectors the Senate was acquiring a valuable store of information. The Senate had also investigated the general question of the salaries of the teaching staffs; it was largely want of money, and the Principal hinted that gifts for the augmentation of salaries would be very welcome. The grants for scholarships had been increased from £1,800 to £3,000 a year; this had made it possible to establish two university post-graduate travelling studentships open to internal and external graduates in all faculties, and three post-graduate studentships open to the faculties of theology, arts, laws, music, and engineering.

Correspondence had passed during the year between the University and the Treasury upon the subject of the Bloomsbury site, but this matter, so important a chapter in the history of the future, still remained for decision. The departmental committee established by the President of the Board of Education had been sitting for some months to consider the final report of the Royal Commission on University Education in London (1913), and to indicate the principal changes now most needed in the existing constitution of the University of London. Its findings might be awaited with confidence, remembering that, in whatever form the body of the University constitution might be moulded, the spirit which gave it life and growth remained.

The annual service for graduates was held at Westminster Abbey at 5.45, and a graduation dinner followed at Drapers' Hall at 8 p.m.

## MEDICAL RESEARCH FUND.

Applications for grants from the Thomas Smythe Hughes Medical Research Fund for assisting medical research must be sent to the Academic Registrar (from whom full particulars can be obtained) by June 15th.

## UNIVERSITY OF GLASGOW.

The History of Medicine prize has been awarded to Dr. Dan McKenzie (London) for his essay entitled "The infancy of medicine." This is the first award of the prize, value £50, founded by a professor in the Faculty of Medicine.

## ROYAL COLLEGE OF PHYSICIANS OF IRELAND.

W. H. ASHMORE has been admitted a licentiate in medicine of the College.

## CONJOINT BOARD IN SCOTLAND.

The following candidates have been approved at the examination indicated:

D.P.H.—D. G. Anderson, M. J. Bell, A. H. Campbell, Agnes F. Dickson, W. Fraser, Clara F. Gertzen, Jean M. Gilchrist, Mary M. Jack, J. C. Lindsay, P. L. McKinlay, Elizabeth P. Y. Paterson, G. H. Percival, W. C. Sharp, Annie V. Taylor, J. Walker, Elizabeth Wheatley, A. H. Williamson, Anne C. Wilson. Part I: Ruth M. Allanson, Mary V. F. Beattie, Elizabeth S. Cook, Elsie B. Dickson, Jane T. Gilmore, Hilda R. Hay, R. Levinson, W. R. Logan, Elizabeth M. Mackay, R. Norton, Margaret M. Paterson, J. Sachs, D. A. M. Shearer, M. Somerville, Jeanie M. Strathie, H. W. Sutherland. Part II: G. A. Pollock.

## Medical News.

THE Leicester Medical Society has issued invitations to the opening of the Leicester Private Hospital on Wednesday afternoon, May 20th. The new hospital, in Regent Road, is the gift of Mr. T. Fielding Johnson, J.P., late chairman of the Leicester Royal Infirmary. It has been built and equipped, as far as possible, with all the facilities and conveniences of a voluntary hospital. The object of the donor has been to make available for the use of private patients the advantages of a modern hospital. The capital outlay having been given, it is intended that, as regards its maintenance and upkeep, the hospital shall be managed on a self-supporting basis. It is open to the patients of any medical practitioner, with no restriction upon free choice of doctor. There is accommodation for fifty patients, mostly in single rooms, and provision has been made for the reception of medical, surgical, and maternity cases.

A FESTIVAL dinner in aid of the funds of the Infants Hospital, Vincent Square, Westminster, was held at the Guildhall on May 8th, under the chairmanship of H.R.H. Prince Henry, who read a telegram from his sister, Princess Mary, president of the hospital, wishing success to the occasion. In proposing the toast of "The Infants Hospital," Prince Henry said it was the first of its kind to be established in Europe; it was founded with the object of placing on a scientific basis the management of infants up to 5 years of age, the treatment of diseases of nutrition, and the investigation of means by which infantile mortality could be prevented. A subscription list of £15,000 was announced, which included £4,500 subscribed by friends of the hospital for the endowment of nine cots at a cost of £500 each, in honour of His Royal Highness's presidency at the festival.

THE annual prizegiving at the London Hospital Medical College will take place on Tuesday, June 2nd, at 3 p.m. The prizes and certificates will be distributed by Dr. Charles H. Mayo of Rochester, Minnesota, in the Medical College library, and the distribution will be followed by a garden party in the hospital grounds.

H.R.H. THE DUKE OF YORK has accepted the Honorary Presidency of the thirty-sixth Congress of the Royal Sanitary Institute to be held at Edinburgh from July 20th to 25th, at which the Secretary for Scotland will preside and deliver the inaugural address.

THE annual general meeting of the London and Counties Medical Protection Society will be held at the offices of the society, Victory House, Leicester Square, W.C.2, on Wednesday, May 20th, at 4 p.m.

THE bi-annual dinner of the Aberdeen University Club, London, will be held at Gatti's Restaurant on Thursday, May 21st, at 7.30 p.m. The Hon. Sir Arthur Greer will be in the chair, and Sir Leslie McKenzie, M.D., will be the guest of honour. Dr. Milligan, 11, Upper Brook Street, W.1, will be pleased to hear from either men or women graduates wishing to join the club or attend the dinner.

THE Fellowship of Medicine announces that Dr. T. W. Eden will lecture at No. 1, Wimpole Street, on May 18th, at 5.30 p.m., on the prevention of puerperal sepsis. On the same date will begin the two weeks' course for general practitioners at the London Temperance Hospital; at 4.30 p.m. a clinical demonstration will be given, and at 5.30 a brief lecture. A special course will be held at the Infants Hospital from May 18th to 30th, and a two weeks' afternoon course in dermatology has been arranged from May 18th to the end of the month by the Hospital for Diseases of the Skin (Blackfriars); a special demonstration of cases will take place on May 19th. During June there will be courses in diseases of the chest at the Victoria Park Hospital for Diseases of the Heart and Lungs, in gynaecology at the Chelsea Hospital for Women, in tropical medicine at the London School of Hygiene and Tropical Medicine, in urology at St. Peter's Hospital, in venereal diseases at the London Lock Hospital, and an intensive course in general medicine, surgery, and the specialties at the London Temperance Hospital. Full particulars may be obtained from the Secretary of the Fellowship of Medicine at No. 1, Wimpole Street, W.1.

A SUMMER school of maternity and child welfare will be held in London, under the auspices of the National Baby Week Council, from July 1st to 7th. Sir Arthur Newsholme will preside over a session dealing with maternal mortality and morbidity in childbirth, the introductory address being contributed by Dame Janet Campbell, M.D. Addresses will also be given by Dr. A. E. Giles, on medical preventive measures; by Dr. Mabel Brodie, on the social problem of establishing preventive measures for combating maternal mortality and morbidity; and by Dr. James Fenton, on the administrative aspect of preventive measures. Visits will be paid to hospitals for children and other institutions of interest to child welfare workers. The full programme may be obtained from the Secretary, National Baby Week Council, 117, Piccadilly, W.1.

At a meeting of the Royal Microscopical Society to be held at 20, Hanover Square, at 8 p.m., on Wednesday, May 20th, Dr. R. J. Ludford, of the Institute of Anatomy, University College, will read a paper on the cytology of cancer.

THE annual medical missionary breakfast of the Medical Prayer Union will be held on Wednesday, May 20th, at the Rectory, University College, Gower Street, W.C., at 8 a.m., under the presidency of Mrs. Scharlieb, C.B.E., M.D., M.S. An address will be given by Dr. E. J. Pelli, of Tsangchow. An intimation of intention to be present will be welcomed by the honorary secretary, Dr. Tom Jays, Livingstone College, Leyton, E.10.

THE late Sir G. Anderson Critchett, Bt., surgeon oculist to the King, who died in February last, left estate of the gross value of £92,150, with net personality £91,632. He has bequeathed £100 each to Epsom College and to the Royal Medical Benevolent Fund.

THE seventh Congress of the Middle German Surgical Association will be held at Chemnitz on June 6th and 7th, when the following subjects will be discussed: modern treatment of carcinoma of the rectum, introduced by Professor Reichel; surgical treatment of pulmonary tuberculosis, introduced by Dr. Wendel of Magdeburg.

In his report for 1924 Dr. Walter Garstang, the medical officer of health for the urban district of Hucknall (population 17,760), states that the small-pox outbreak which began in August, 1923, continued throughout 1924. The total cases in 1924 were 193, and all were removed to hospital. The vaccinated numbered 37 and the unvaccinated 156. Of the vaccinated none were under 20 years of age, and 15 were vaccinated after exposure to infection. The disease has been of a very mild type, and the medical officer is emphatic that it can be stamped out only by vaccination, and that, looking to the continued neglect of vaccination, cases of small-pox may be expected for a considerable time—probably for years.

DR. J. G. MACQUEEN of the Middle Temple, and Drs. W. R. H. Heddy and R. B. Davidson of Gray's Inn, were called to the Bar on May 6th.

THERE has been a reduction in mortality from tuberculosis in Germany from 26 per 10,000 inhabitants in 1919 to 11.5 in 1923. Germany possesses 514 sanatoriums for tuberculosis, with a total of 43,000 beds.

THE following foreign appointments have been recently announced: Dr. Stoeltzner of Halle to be professor of children's diseases in the University of Königsberg; Dr. H. E. Sigerist of Zürich to succeed Professor Sndhoff in the chair of the history of medicine at Leipzig; Dr. Ceelen to be professor of morbid anatomy at Greifswald University in succession to Professor Grosz; Dr. Eric Hessé to be professor of surgery at Leningrad; Dr. Ombredanne to be professor of the surgery of childhood and orthopaedics, and Dr. Roussy professor of pathological anatomy, in the Paris faculty of medicine; Dr. Lecercle to be professor of clinical surgery in the Damascus faculty of medicine; Dr. C. Roques has been nominated professor of medical physics in the Bordeaux faculty of medicine in place of the late Professor Bergonié; and Dr. Patel has been nominated professor of operative surgery in the Lyons medical faculty.

THE late Mr. J. David Williams of Styal, Cheshire, a director of the Manchester Ship Canal Company, has left estate of the gross value of £634,959, with net personality £529,080. He has bequeathed one hundred £10 fully paid up preference shares in the Manchester Ship Canal Company each to the Manchester Royal Infirmary, for cancer research; to the Ancoats Hospital and Ardwick and Ancoats Dispensary, to endow a J. D. Williams bed; and to St. Mary's Hospital, Manchester, to endow a J. D. Williams bed.

WE have received the first issue of the *Journal of the Australian Veterinary Association*; it bears date March, 1925. It is edited by Mr. M. Henry, with the assistance of an editorial committee, and is issued from the Veterinary School of the University of Sydney. It contains several original

articles, and a report of the fourth general meeting of the Australian Veterinary Association held in Adelaide last year. It is intended to keep veterinarians in Australia acquainted with the progress of their art and also to let the rest of the world know what is being done in Australia.

THE first International Child Welfare Congress will be held in Geneva from August 24th to 28th, under the patronage of the Swiss Federal Government, and it is anticipated that about 1,000 delegates from fifty different countries will be present. Papers will be contributed by Sir Henry Gauvain, Mr. R. C. Elmslie, Dr. Cyril Burt, and Dr. D. C. Kirkwood. The congress will be divided into three sections, the first dealing with hygiene and medicine, under the presidency of Professor Clémens Pirquet, director of the children's clinic at the University of Vienna; the second, concerned with social welfare and administration, under the presidency of Mr. George Scelle, professor of international law at Dijon; and the third, which will discuss educational propaganda, will be presided over by the Marchioness of Aberdeen, president of the International Council of Women.

ONE of the results of the earthquake in Japan has been a great deterioration in the sanitary conditions. During 1924 three times as many cases of typhoid fever occurred as in 1923; 3,863 cases were admitted to hospital, and 198 deaths were due to this cause in November alone. Infantile mortality in Japan is also very high.

THE Dutch Congress of Public Health will be held at Leenwarden on June 26th and 27th.

WE regret to announce the death, on May 13th, of Dr. Howard H. Tooth, C.B., C.M.G., consulting physician to St. Bartholomew's Hospital and to the National Hospital for the Paralysed and Epileptic. We hope to publish an obituary notice next week.

## Letters, Notes, and Answers.

ALL communications in regard to editorial business should be addressed to **THE EDITOR, British Medical Journal, 429, Strand, W.C.2.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *BRITISH MEDICAL JOURNAL* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Matter intended for the current issue should be posted so as to arrive by the first post on Monday, though in special circumstances urgent communications can usually be received on Tuesday morning.

Authors desiring REPRINTS of their articles published in the *BRITISH MEDICAL JOURNAL* must communicate with the Financial Secretary and Business Manager, 429, Strand, W.C.2, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *JOURNAL*, should be addressed to the Financial Secretary and Business Manager, 429, Strand, W.C.2. Attention to this request will avoid delay.

THE TELEPHONE NUMBER of the *BRITISH MEDICAL ASSOCIATION* and *BRITISH MEDICAL JOURNAL* is **GERHARD 2630** (Internal Exchange).

THE TELEGRAPHIC ADDRESSES are:

EDITOR of the *BRITISH MEDICAL JOURNAL*, *Antiology Westrand, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westrand, London.*

MEDICAL SECRETARY, *Mediscra Westrand, London.*

The address of the Irish Office of the *British Medical Association* is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 4737 Dublin), and of the Scottish Office, 6, Rutland Square, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 4361 Central).

## QUERIES AND ANSWERS.

"IGNORANUS" asks whether there is any record of injections of adrenaline, used for the relief of spasmodic asthma, inducing eczema or aggravating an existing attack of eczema.

## INCOME TAX.

### Additional Assessments.

"M. H." (Kent) has received notices of assessment for the three years 1921-22 to 1923-24, that for 1921-22 being the second additional notice. What are his chances of appealing successfully?

\* We should advise our correspondent to write to his local inspector of taxes giving formal notice of appeal, to keep himself right as regards the time limit, and asking for information as to what precise fees or emoluments the assessments cover. It is at least possible that it may be found that the additional assessments may relate to some particular earnings which have been included in the general Schedule D return and already assessed accordingly.

*The "Cash Basis."*

"E. N. B." has been assessed on the "cash basis" for the last seven years in respect of the same practice. He has now been requested to state the amount of his outstanding book debts, presumably with a view to the alteration of the basis from "cash receipts" to "bookings."

\* \* This matter was discussed in November, 1921 (see SUPPLEMENT to the BRITISH MEDICAL JOURNAL of 19th of that month), between a principal inspector at Somerset House and two officials of the Association. "E. N. B." may usefully refer to the account given in the SUPPLEMENT; it may suffice to say here that the attitude of the authorities appears to be to regard the cash basis as well adapted to the assessment in normal circumstances of medical practitioners and as the usual custom, to be departed from only where special circumstances render it inequitable. "E. N. B." might point this out to the inspector of taxes and inquire what, in his opinion, are the special circumstances which require a departure from the normal custom in his case. In the last resort, "E. N. B." should insist on deducting from the nominal amount of his book debts a reasonable amount for (a) cost of collection and (b) irrecoverable debts.

## LETTERS, NOTES, ETC.

*"RELIABLE."*

DR. WILLIAM L. STOREY (Belfast) writes: In the instructive editorial, "The suffix '-itis,' in your issue of March 28th, reference is made to the disappearance of the word 'trustworthy' and its replacement by 'reliable.' According to the *New English Dictionary* that piece of bad money, as you would call it, was first uttered only about 1850, and the earliest illustration is from one of Gladstone's writings: "1857—Gladstone in *Oxford Ess.* He seems to think that the reliable chronology of Greece begins before its reliable history." The Grand Old Man revelled apparently in the use of that word, but later on his addiction was cured by Dean Stanley. Mr. Frederick Locker-Lampson in *My Confidences* describes how it was effected: "Dean Stanley complained that, much as he had seen of Gladstone, and often as he had talked with him, he did not think he had ever influenced him in anything. 'Yes,' said the Dean, recollecting himself, 'I influenced him in one matter. I told him he ought never to use the word *reliable*, and I gave him my reasons. Some time afterwards I met Gladstone in the street, and he said, as we parted, *I have never used that wretched word 'reliable' since you spoke to me about it.*" Curiosity prompts one to ask, What were the reasons which the Dean advanced with such beneficial effect?

## RELIEF OF PAIN IN BURNS AND SCALDS.

DR. E. NICHOLAS HUGHES (Wallasey) writes with reference to the note by Dr. W. F. Moore (Kingsbury) on the treatment of burns and scalds (May 9th, p. 908): When acting as a house-surgeon some three years ago I used a treatment for the relief of pain in burns and scalds which I found extremely efficacious. The affected part, after cleansing and removal of fragments of clothing, was covered with a solution of novocain (1/2 per cent.) the part covered with white lint. In very extensive burns and scalds opium was given by mouth. Young children treated in this way were often soundly asleep within an hour of being admitted into hospital. I have applied the novocain treatment to very young babies, with no signs of toxic effect. It is difficult to sterilize caron oil; liquid paraffin can be readily sterilized without undergoing decomposition.

DR. REGINALD COCK (London, E.2) writes to draw Dr. Moore's attention to the following statement in Whitt's *Pharmacy, Materia Medica, and Therapeutics* (tenth edition): "Opium has no sedative influence on sensory nerve endings, hence it is a mistake to employ the drug or its alkaloids for the local relief of pain."

## PAIN-RELIEF AND TEETH EXTRACTION.

DR. CYRIL H. COCK (London, E.2) writes in reply to "Borneo" (May 9th, p. 908): I would adopt to prevent excessive haemorrhage following extraction of the teeth would be to get the gums in as healthy condition as possible by removing any salivary calculus; mouth-washes, etc., before the operation. I should for forty-eight hours dose the patient with calcium lactate, 20 grains three times a day, and an hour before extraction inject 2 c.cm. of haemoplastin (P., D. and Co.); 2 c.cm. or more later if necessary. The extraction should be carefully done, and the alveolus well pressed into place directly after extraction. The patient should then remain quiet in a sitting position. If any haemorrhage of serious nature occurs, plug with oil of turpentine.

## DANGERS OF ZINC STEARATE DUSTING POWDERS.

ON August 16th, 1924 (p. 255), we referred to the dangers of zinc stearate dusting powders reported by American investigators. At a meeting of the board of trustees of the American Medical Association in June, 1924, a special committee reported that it had obtained no evidence that zinc stearate dusting powders

possessed any advantages over other dusting powders, and that special containers with permanently attached covers were essential in order to prevent infants from being poisoned. A second report by this committee (*Journal of the American Medical Association* of March 7th, 1925, p. 750) states that details of 131 cases of poisoning had been received, of which 28 terminated fatally. The committee had also obtained indirectly reports of many other accidents arising from the use of zinc stearate powders, and considered the danger greater than was originally surmised. A conference was arranged with the manufacturers and distributors of these powders at the end of October, 1924, and subsequently it was unanimously agreed to adopt a self-closing type for containers, and further consideration was given to the number, size, and shape of openings in it. A precautionary statement on the label was held to be desirable, and it was agreed that this should be submitted by the manufacturers to the committee for its approval. The committee, therefore, recommended that, in view of this action on the part of the manufacturers, no steps should be taken by the Association for the introduction of legislation, but that all manufacturers of these powders should be requested to use such a self-closing container, and also that the use of zinc stearate as a dusting powder for infants should be discouraged by the medical profession.

## STAGES OF DRUNKENNESS.

DR. J. GOOD (Tenbury) writes: Having unfortunately had considerable experience of drunkenness, I suppose I ought to express my opinion thereon. As idiosyncrasies vary in different persons, so do the effects of alcohol on individuals. Some may consume a lot, others but little, before entering on the stages of drunkenness. Those are:—(1) *Fool*: When the whole vitality is apparently stimulated and the man becomes merry, restless, witty, and facetious. In this stage in motor he may take on and successfully negotiate increased risks. (2) *Knave*: When his higher moral nature is dulled and he becomes more indifferent to right and wrong, and more careless in motor driving. (3) *Ruffian*: When his higher moral nature is in abeyance his animal instincts are more conspicuous. He may become vicious on trifling matters—for example, should another car pass him—and a public peril. (4) *Lost beneath the fumes of his* ... the road and sleep off his debauch, or if suffocated. He is unable to drive a car. (5) *A corpse*: At the disposal of the coroner. As regards diagnosis, the surgeon must use his own powers in differentiation, discreetly remembering that difficult pronouncements, chalk lines, and poises alone are unreliable, and that the police constable, being more familiar with the accused and with his type of humanity, may be better able to judge of a deviation from his normal condition. The shock of detection or accident may recover a man in stage 1 or 2, but he is too fortified in stage 3. Speaking for the chauffeur, "he may drive a car in stage 1," but, speaking for the public, "not at all," as the public becomes to him of decreasing importance from the beginning.

## LITERARY NEOLOGISMS AND BARBARISMS.

"M.A., M.D." writes from India: May I be allowed to enter what I hope will prove a timely protest against the threatened introduction into English medical literature of barbarisms such as "to evaluate," instead of "to value"; "to stress," instead of "to lay stress upon"; "view point," instead of "point of view"; "such and such diet was fed to such and such an animal," instead of "such and such an animal was fed with such and such diet"; and the like? I would quote in this connexion the exceedingly apposite remarks of Peter Mark Roget, himself a member of our profession, on the use of such expressions in the beautifully written introduction to his well known *Thesaurus of English Words and Phrases*:

"Some modern writers, however, have indulged in a habit of ... raw words and a new-fangled phraseology, ... with manifest injury to the purity of the ... practice, the offspring of indolence or conceit, ... perfect of the riches in which the English applied them with the same meaning 'their own fancy.'"

## ANTHRAX IN TANGANYIKA.

DR. OWEN FITZPATRICK (Singida, Tanganyika Territory) writes to record the fact that during March seven cases of anthrax had been reported, all amongst natives. Of the two cases it was possible to admit to hospital both presented typical cutaneous lesions—in the one case of the shoulder, and in the other of the abdomen. The infection had occurred some four days before. There were ... and the treatment was purely local. Of the other five cases one was fatal and the meat from an animal that had died.

## VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 38, 39, 40, 41, 44, and 45 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 42 and 43. A short summary of vacant posts notified in the advertisement columns appears in the Supplement at page 207.

## An Address

ON

THE IMPORTANCE OF EXPLORATORY INCISION  
IN CANCER OF THE BREAST.\*

BY

DUNCAN C. L. FITZWILLIAMS, C.M.G., M.D.,  
C.R.M., F.R.C.S.,

LECTURER IN CLINICAL SURGERY, ST. MARY'S HOSPITAL, LONDON.

LECTURES given to students and addresses given to practitioners are two different things; one dogmatizes in the former, and the student, having no experience, has perforce to take what is offered him. The practitioner, however, is a person who has experience, who has formed his own opinion. We all have our own ideas—some may be right and some may be wrong; but in any case we have formed them slowly and we shall only change them slowly. At the same time, it is difficult to gauge how much of our original teaching tinges our views, biases our minds, and governs our judgement. At first it must do so very largely, as time goes on to a less and less extent; to a less and less extent, too, as we keep ourselves abreast of the times and hear new views. It is with this object in view, doubtless, that you ask men from the teaching schools to address you.

In this sense I come to lay before you my views on what I believe our procedure should be in connexion with the early diagnosis of cancer of the breast. These views represent the present trend of thought, or the direction in which I hope we are travelling; they are by no means final, and will probably be changed in the next generation, but you will find that they resemble in no way the teaching of twenty years ago. These views may seem extreme to some because they are new, and all new views seem at first extreme; but they will presently be accepted by all, taught in our medical schools to the younger generation, and pass in time into the limbo of what is old-fashioned.

In the first place, it will be as well to define what is here meant by "early carcinoma of the breast." To me it is an indefinite something or an undefined thickening—we are not quite sure; it is difficult to make out; at all events, there is not a single sign of malignancy, and nothing even to bring malignancy to mind. That, I consider, is possibly early cancer of the breast. Anything which has any characteristic of malignancy I no longer regard as early; it is sufficiently well established to give rise to signs and symptoms. This early stage is the time at which cancer of the breast can be diagnosed if we will do it, and that is the time, and the only time, that we can almost guarantee a cure to our patients.

The breast is the one place where cancer is seen early; it is the one place in which a radical operation can be performed—that is to say, it is the one place in which the growth, the glands, and the whole lymph field is removed in one. Compare it with carcinoma of the abdominal viscera: in the abdomen we cannot even begin to suspect cancer until symptoms develop; ulceration occurs and blood is passed, diarrhoea is constant or obstruction threatens; but even then we may not be able to locate it, above all we can do nothing approaching a radical operation. Compare it with a superficial growth like epithelioma of the lip; we remove the growth and also the glands of the neck; we do not remove the lymphatics by which spread has taken place, neither can we remove all the glands of the neck, but we rest content with what we do; luckily, epithelioma is not nearly as malignant as cancer of the breast, and therefore our results escape criticism. In cancer of the tongue, to take another example, we remove the growth and we remove as many glands as we can: many glands are, however, left behind, and the lymph

field is untouched; our results are what we should expect in such cases.

All know the signs and symptoms of cancer of the breast, so I need not waste time upon them except to draw attention to the fact that they are all due to one thing—namely, extension of the growth. The growth must extend for these symptoms to be suspected, to appear, and to develop. We need, therefore, only assign their appropriate value to each of them in their order of importance.

Fixity of the skin is the earliest sign of malignancy it is possible for us to have, and is the most suspicious and significant. But the time at which it develops is not constant. Gross saw it develop in about two months, but states that it is usually about fourteen months before it is developed. Fourteen months is a long time to wait in order to get the first sign of malignancy. If the onset of the cancer is in the superficial parts of the gland, then the skin is attacked earlier than if it starts in the deeper portions. It is seen better and earlier in a thin person than in one in whom there is a thick layer of adipose tissue. A cancer may therefore become well established before even puckering, wrinkling, and anchoring of the skin develops at all. There are other conditions, too, in which it is found: old fibro-adenomata, chronic abscess, tuberculous masses, and occasionally in chronic mastitis.

Retraction of the nipple is the next sign of importance, and this, again, is quite inconstant. It is present early in cancer which starts near the nipple, and is absent till quite late, and may never develop, if the cancer starts at the periphery of the gland. Another important fact is that in the rapidly growing carcinomata the opposite may occur, and the breast become prominent and the nipple protrude, while it is well seen in the less malignant and more atrophic forms. It is also present in any chronic condition in which fibrous tissue forms, so that it is met with in chronic abscess and chronic tubercle.

Enlargement of glands in the axilla is a sign to which some attach great importance, but personally I think it one of small significance. Cancer can hardly grow without being accompanied by chronic mastitis, and chronic mastitis nearly always causes enlargement of the axillary glands. In addition every form of inflammatory change will cause enlargement of the glands in the axilla, and therefore very little reliance should be placed upon this sign. Far more important really is the feel of those glands; small but very hard glands are far more significant than large ones.

Often enlarged glands can be felt in connexion with cancer of the breast, and yet when examined after the operation nothing malignant is found in them. On the other hand, during the operation small glands are sometimes found right up at the apex of the axilla, in the triangle between the first rib, the clavicle, and the coracoid process, which cannot be felt, are not enlarged, but yet are infected. Stiles pointed this out long ago and drew attention to the fact that it was impossible to feel them. They become infected as a rule through the lymphatics which run upwards between the pectoral muscles and which pierce the costo-coracoid membrane; sometimes there are infected glands lying on the costo-coracoid membrane.

Age is, I think, a great factor in diagnosis; sometimes, however, it is misleading. The commonest age at which carcinoma of the breast occurs is between 45 and 55; all agree upon this. All agree too that after this age carcinoma is very frequent, and I think in the minds of all of us there is the impression that the older a person is the more likely is any given lump to be a carcinoma, and this is true because the inflammatory conditions in the breast are less likely to occur in a withered and functionless organ. There is the general impression too that carcinoma hardly ever occurs in people under 35; nothing, however, could be more misleading. I know of several cases which occurred in the teens. Thompson and Battle and Mayberry reported cases at 11 years old, one of which was a squamous-celled carcinoma; Commichael one at 12 years; Home one at 15, which was bilateral; and Brewer one at 16.

\* Delivered to the Nottingham Medico-Chirurgical Society, January 23rd, 1925.

If we go to the male sex, Blodgett noted carcinoma in a boy of 12 and Bryan in one of 14. A little while ago Professor Pannett took the second breast from a woman aged 34 in St. Mary's Hospital, having removed her other breast nearly eight years previously. Rodman in a collection of 5,000 cases found that 9 per cent. were in people between the ages of 20 and 30. All through the public records you would be surprised at the number of cases recorded, not on account of the age, but for some other reason, in which the age was under 30. So that you cannot exclude carcinoma merely on account of youth, and we must correct the very strong and almost irresistible tendency we all have to do so. We all, in spite of ourselves, tend to acquit a tumour of the breast of being malignant merely because it occurs in a young person, a thing we are in no way justified in doing.

These are the signs upon which we rely for suspicion of cancer. There are others, such as discharge from the nipple, which is very rare; it is present in only about 3 per cent. of the cases. Fixity to the muscle or chest wall, the condition of "pig-skin," ulceration of the skin, enlargement of the supraclavicular glands, are all very late symptoms, and need not be considered. When they are present the question of diagnosis no longer troubles us; we then only have to decide if an operation can still do any good.

#### DIAGNOSIS.

There are three different classes of cases clearly distinguished in my own mind into which the patients may be divided.

In the first category there is the patient who obviously has cancer; the first glance at her breast tells us so. Here all the signs and symptoms which characterize malignancy are fully developed. The nipple is displaced, the veins are enlarged, the skin bound down and may be ulcerated with a fungating and discharging sore, pig-skin appearance widely developed over a large area, and small nodes and nodules visible in the skin round about; large masses are visible in the axilla and above the clavicle. The patient is thin, emaciated, and anxious-looking. She excuses herself for not seeking advice sooner, giving every excuse except the real one—that she was afraid. She regards us anxiously, guiltily, and beseechingly, hoping against hope for a comforting and favourable verdict; but in her own mind she has made the diagnosis, and she has made it correctly without any medical training. What more does the picture need? Fortunately these cases are rarely seen, though probably every practitioner has come across one or more such patients who have hidden their condition till the last moment. Here, then, the problem solves itself.

The next category is where there is a definite mass in the breast, the nature of which is doubtful. Here the question of diagnosis is one of the most important which can be put to the medical man—so much depends upon it. The greatest skill, care, and trouble should be taken to arrive at a correct diagnosis. There is no infallible guide: skill, experience, common sense, and that curious faculty we call intuition, all come to our aid in a way it is impossible to explain.

In the case with which we are dealing the signs are not sufficiently developed for us to differentiate clearly, and the question arises, Are we dealing with a malignant or innocent tumour? An innocent tumour is here taken to include all inflammatory conditions as well as innocent. To take first the probabilities. It is estimated from large numbers of collected figures from various sources that 30 per cent. of all tumours of the breast are malignant and 20 per cent. innocent. That is a proportion of 4 to 1 in favour of malignancy. These figures, to my mind, are not quite accurate; they are derived very largely from hospital records, but records are only kept of those cases which are of sufficient importance to gain admission to the institution, and many small innocent cysts, tumours, and miscellaneous inflammatory masses, of which no records are kept, are dealt with in out-patient departments. We shall therefore possibly be more accurate if we say that 70 per cent. are malignant and only 30 per cent. innocent.

I am putting it as fairly as I can. This, in sporting terms, is nearly 2½ chances to 1 that the condition is malignant—a figure which at once must forcibly attract our attention. With these odds in mind, it is only right, it is only safe, to regard all tumours as malignant until we have proved them innocent. This is the only way in which we can do justice to our patient. We have unfortunately a natural tendency which is almost irresistible to do the exact opposite, and to regard all tumours as innocent till malignant symptoms develop.

The things which guide us to a correct diagnosis are all small in themselves, and we can take them in order.

The presence of pain in a small growth is very much against the mass being cancer; similarly, but to a less extent, is the presence of pain on handling the mass. Inflammatory masses are often more or less painful or tender; cancer is a painless malady till the later stages. Pain is associated with cancer in the minds of the laity simply because the later stages of the disease are familiar to them through their looking after or visiting relations and friends in the last stages of the disease.

Cancer in the later stages, as we all know, is a very painful and distressing disease, wearying, even repellent, and fear-inspiring to those who nurse the patients, but in the early stages it is insidious, quiet, and painless. The fact that cancer is painless till its later stages should be broadcasted widely among the laity, as many do not seek advice for tumours because, as they are painless, no alarm is caused.

The presence of masses in both breasts is against cancer and in favour of interstitial mastitis; cancer very seldom starts in both breasts at once. It is said that if at this stage a tumour can be felt with the fingers, but is impalpable to the flat of the hand, this is against its being cancer; but it is a sign that I am rather chary of mentioning, as great stress is often laid upon it as a way of telling whether cancer or chronic mastitis is present, though as a sign to tell this it is quite useless and, as we now regard matters, mischievous and misleading; a small cancerous mass is quite as impalpable to the flat hand as is chronic mastitis. Moreover, chronic mastitis may be present in which cancer is starting, but has as yet none of the characteristics of cancer.

The margins of the tumour should be carefully considered, for the margins of a scirrhus are usually much better defined than those of an inflammatory mass. This, however, does not hold good if the scirrhus is rapidly extending, while sometimes the edges of a chronic abscess are remarkably well defined.

Dimpling or the slightest adhesion of the skin, as already stated, is very much in favour of malignancy, but is not pathognomonic. The hardness of a scirrhus is rarely attained by any other tumour, but sometimes the mass is too deeply situated for this to be made out, and hardness can easily be simulated by a tense cyst. Enlarged veins seen coursing over the tumour are in favour of malignancy.

Lastly, there is the important fact that cancer rarely takes origin at the time of lactation; it does so sometimes, we all know, but it is rare, while this is the favourite time for inflammatory conditions to start.

These, then, are the various points which guide us in difficult cases. Sometimes, of course, they are insufficient to guide us correctly, and therefore an exploratory incision should be made before performing the radical operation, or else with the best intention in the world serious mistakes will be made. Now this is the ordinary case which presents itself to us in the usual course of events, and it is the one which some are still inclined to call "early cases" just because malignancy is not written across the chest by the display of every malignant characteristic.

The third category is the one to which our attention is especially directed. Here there is only an indefinite lump. We may suppose it is deep seated in a voluminous breast so that nothing definite can be made out. Examination prompts us to say that there seems to be a vague thickening in the breast that should not be there, but beyond this there is nothing whatever to be felt. There is not even the certainty that there is anything, beyond perhaps some-

thing that feels like a slight mastitis; signs and symptoms of malignancy do not arise. This is the problem which I am going to ask you to regard as the problem of the early case. The patient is 50 years of age; what advice is to be given to her? Yours is the responsibility.

Well, there is the ordinary thing which is so easy to do, which is a ready way out of the difficulty, and which will be pleasing and acceptable to the patient; that is to say to her, "Yes, perhaps I can feel a little thickening in your breast, but that is not surprising at your time of life; in fact, it is almost normal; do not take any notice of it. Come and see me in a month's time." A month passes and there is no perceptible change. Another month, and yet a third pass, and perhaps the mass is a little larger; it is deep seated; it is very difficult to say definitely; you reassure her, and perhaps you do not see her for two or more months; you have said, "There is nothing to be alarmed at," and she is not nervous about it. In any case you say to yourself, "There certainly is no sign of malignancy—no harm can come from waiting." Six or eight months pass, and now there is a mass for sure; perhaps the skin does not slide over it quite so freely, but if the mass is deep seated and the person is fat the skin may be quite free, so that even yet there is no sign of malignancy. Perhaps the practitioner suggests a consultation, not as necessary really, as you have already committed yourself by saying the condition is nothing, but merely advisable; the patient demurs—she feels so much better, the liniment is doing her good, she is sure the lump is smaller; and in this way ten to twelve months may have passed before a consultation is arranged and an operation suggested.

An operation is performed and cancer is found. We still regard the condition as early, but if it is early now, what was it twelve months ago? I do not think that I have drawn the picture inappropriately or exaggerated it; we have lost a year. We have acquitted the lump of being cancer merely because it was small, had not spread and infiltrated the tissues sufficiently to enable us to say that it was malignant. We have been oblivious to the obvious fact that cancer must begin in a microscopic area and has at first no sign of malignancy, and we have forgotten the 2½ chances to 1 that it was malignant to start with; we have failed to treat the condition as malignant until it was proved innocent. Many writers have endeavoured to calculate the average time the mass has been suspected before it comes to the surgeon, and different observers have varied from a year to thirty months as the time lost.

This method of procedure does not seem to be unusual; we were brought up "to watch such cases carefully." It is what we are used to, and it does not seem strange—in fact, you say it is the obvious, the ordinary, and the best thing to do. But it means, in blunt English, that we are going to do nothing *except waste time*. Curiously enough, we do not realize this. But let me put it to you, Is there any other condition in which the chances are 2½ to 1 in favour of malignancy in which you would knowingly waste a year in order to be certain? If there is, then I do not know it. Let us reduce the matter to absurdity: Why have you waited? You will say, In order to be certain. But you were not certain when you operated—why not wait another six months till all the symptoms of malignancy gradually blossom forth? You then really will be certain. You say, That would not be fair. My reply is that it is as fair to wait now as it was to wait then, with the chances always 2½ to 1 against the patient. You waited at the only time when operation held anything approaching a certainty of cure. You should have held the mass to be malignant until it was proved innocent. What right had you to say to the patient, "It is nothing," simply because you did not know?

The Johns Hopkins School teaches—and I believe it is right—that the development of any malignant sign whatever diminishes the patient's chance of cure by 25 per cent. Moreover, what has been done while we have waited? Ointments and liniments have been energetically applied to the breast, which has been well massaged. And when we consider that the spread of the cancer is by the cells passing

along the lymphatics, is not massage of this sort the very last treatment we should care to apply? Yet I can assure you it is ordinary treatment, and the only form of treatment if anything is done at all.

Having waited, then, till some symptoms of malignancy have developed, the patient is operated upon. The best results we have of operations at the present day are—39 per cent. living and well at the end of five years, 61 per cent. dead or dying. This analysis is from America; no other analysis gives such favourable figures. There is a very marked difference in the results we get from private cases and those we get from hospital cases; the former are much better than the latter, the difference being due to the fact that we see private cases usually at a much earlier date. I should be surprised if 20 per cent. of the hospital cases were alive and well at the end of five years. Surely this is a poor result for surgery. No wonder every form of treatment has its loud-throated advocates, and every form of treatment can always produce its cancer cures, from violet leaves through the range of pastes up to the more orthodox procedures such as injections of selenium, lead, and gold, right up to the palliative treatment supplied by x rays and radium. If these are the results of surgery, surely every one of these methods is justified. The only thing that the surgeon can boast is that, had as his results are, they are infinitely better than those of any other form of treatment.

Such, then, is the result of adopting the plan I have indicated. Is there no better plan? I think there is, and one I would earnestly ask you to try.

The woman is 50 years old, with this indefinite thickening and no more, and we are to advise her to the best of our ability. By no possible means of examination can we make a diagnosis by the ordinary methods, therefore we must adopt new ones. The answer to our doubt can be given to us without delay, and without dulicity, if we will remove the suspected mass and have it examined under the microscope by an expert. If it proves to be simple, we then can say to the patient, "It's nothing—you can now set your mind at rest," and we have now good authority for saying so which we never had before. If it proves to be malignant it can be removed at a time when she has the greatest possible chance of cure.

We need not go into the technique of the procedure, beyond saying that a circumferential incision can be made in the sulcus between the breast and the chest wall, the breast turned upwards, and the mass removed from the back of the breast. Radiating incisions are made outwards from the nipple, and a piecrust-shaped piece removed. The edges are seared with a cautery to prevent the escape of cancer cells in the event of its proving to be a carcinoma; the raw surfaces are sewn up and the breast replaced. The nipple is not interfered with, and there is no visible scar left. If preferred the pathologist can be present, and by means of a freezing microtome examine the mass then and there, and if necessary the complete operation can then be proceeded with in the event of the mass proving to be cancer. I prefer, however, the more methodical examination in the laboratory, where it can be conducted without haste, as I think a truer estimation can then be formed. Sir Lenthal Cheate shows how difficult it is to decide, even by the microscope, as to whether the mass is really early cancer or not by the examination of only one or two sections. In these early cases the whole mass must be carefully searched and any suspicious piece cut separately. The search must be carried out by a skilled person; it cannot be done by the laboratory boy.

By this means we can avoid the delay which accompanies the other and the commoner method of arriving at a diagnosis, and we place our patient in a far happier position with regard to the result.

I have drawn attention to the best statistics we have of the results of operation, and they are poor enough, and I have also conscientiously gone through all the cases of breast carcinoma of St. Mary's Hospital since 1900, and have written to a great many of the people operated upon in recent years. I cannot give the exact figures as I have

not made them out, but our hospital results are not anywhere near as good as the figures of private cases. I tell all my breast cases to come and see me after the operation, and I try to keep an eye upon them every so many months. I do not believe 20 per cent. of them are alive and well after five years. Surgeons will give many instances of people alive and well after the five years mentioned, but I believe the bulk of these are private patients; I myself have them up to seventeen years. But in private, whatever the delay may be, we see them, as a rule, far earlier than we see the hospital cases.

For my own part I freely admit that in the best cases I have the operation on the breast in the first place was not done with any idea of cancer, but always for chronic mastitis, and the cancer found later and the whole breast removed. That is the secret of the best of my cases, and that is how the importance of avoiding delay became impressed upon me. I believe that if operations for cancer of the breast could be carried out at this time there is no reason why we should not have 75 per cent. alive and well at the end of five years.

In the last twenty years the operation on the breast has quadrupled its gravity, but I do not think it has as much as doubled its benefit to the patient, and much even of that benefit is due to earlier operation, for the dread of operations is less now than it was. The extent of the operation has reached its limit, and if our results are to improve, as I am confident they can, then it must be by earlier diagnosis; and earlier diagnosis along the lines I have just indicated is bound to come.

I know the objection that will be raised is that many early cases would be operated upon in which no malignancy was found, and therefore the operation need not have been performed and is therefore unjustifiable. But the preliminary operation is a comparatively slight one; it leaves no visible scar, and if nothing serious is found the patient's mind can be set at rest; she is rid of the mass, and she is all the better for being rid of it. Does not getting rid of the mass and the giving of a definite diagnosis compensate and justify the proceeding? Think, too, what we gain every time we do find a cancer. How many cases of obscure abdominal disease undergo an exploratory operation and nothing is found? but the operation is not held to be unjustified. How many cases of obscure abdominal trouble are operated upon, and an apparently normal appendix removed? But it is not therefore said that the operation was unwarranted. How many times are gall stones diagnosed and at the operation no gall stones are found? We all know these cases, but we do not say that we have done more than take proper precautions.

Those who were at hospital twenty-five or more years ago can recall how few were the operations for gall stones or for appendicitis then seen. We were only beginning to operate upon these cases, and now they are more than common. Before that time exploratory operations upon the abdomen were unheard of; now they are a matter of common practice, and are carried out on quite slight grounds—the suspicion of gall stones or appendicitis, enteritis, chronic constipation, slight obstructive pains the cause of which is obscure; they are exploratory and diagnostic, and therefore considered necessary for diagnosis. The likelihood of cancer is certainly present, but it is not the formidable bogey it is when we are dealing with the breast. Nothing is thought of exploratory abdominal operations, but the same people will often object to having an exploratory operation performed on the breast, though no one could compare the severity and seriousness of the two operations.

Believe me, the same change which has come in your lifetime in the case of appendicitis and gall stones is going to come in the case of the breast, and exploratory operations will in time be common, and greatly to the benefit of the patient. It may be a new doctrine now, but in a few years it will be the ordinary teaching of all medical schools, and the "wait and see" policy will be a thing of the past; it will be that policy which will be called unjustifiable, and the more we think of it the more unjustifiable it is from every point of view.

## THE CAUSATION AND PREVENTION OF RICKETS.\*

BY

A. WEBSTER AND LEONARD HILL.

(From the National Institute for Medical Research.)

RICKETS is a disease of civilization, and is so frequently found in the large cities of America and Europe that it is doubtful whether the children of the poorer classes ever wholly escape it. Good evidence of a seasonal variation in the incidence of rickets has been shown by many observers—Schnorr, Hansemann, and others. It reaches its height in the winter and declines in the summer. Palm was the first to correlate this seasonal variation with the incidence of sunlight, and thus to anticipate by many years wider discoveries.

### CAUSATION.

Many theories have been advanced to explain the cause of rickets: overfeeding, starvation, intestinal intoxication, defective hygiene, disorders of the ductless glands, and acidosis. The first great impetus to the modern intensive study of rickets was given by the work of Mellanby in this country in 1918. He varied the diets of young growing puppies until he found diets that would invariably produce rickets. To these diets he added various substances, and noted if any effect was produced in the process of calcification. He experimented on a large number of puppies and brought out many interesting facts. His most important conclusion was that rickets was really a deficiency disease—that is, it was caused by the absence from the food of a vitamin, and that the particular vitamin concerned was vitamin A or something closely associated with it. He found generally that fats richest in vitamin A were the most potent in preventing rickets, cod-liver oil being by far the best.

Soon after the publication of Mellanby's work the American investigators, McCollum, Simmonds, Shipley, and Park, and Sherman and Pappenheimer, showed almost simultaneously and independently that rickets could be produced in the rat by diets that were abnormal in their inorganic constituents. Their investigation showed that apart from any vitamin deficiency the essential thing in the production of rickets was to impoverish the diet in the raw materials of the skeleton—that is, in calcium and phosphorus. They found that rickets could be produced by diets poor in phosphorus or in calcium, or by diets that contained these elements in unbalanced amounts. More especially was it shown that a diet with a minimum amount of phosphorus could be made a rickets-producing one by the addition of excess of calcium. Although bone owes its rigid structure to its calcium phosphate content, most previous workers on the subject had, curiously enough, confined their attention to the part played by calcium in bone formation only. It is obvious that calcium without sufficient phosphorus to combine with it is useless to the organism for bone formation, and the work of the American investigators gave this point due consideration. Sherman and Pappenheimer more particularly proved that the form in which the phosphorus was given—that is, as a simple inorganic phosphate or as an organic phosphate in various types of combination—was important. They showed generally that soluble inorganic phosphates were more efficient in preventing rickets.

This work on rats paved the way for extensive work on the part played by deficiency substances in the etiology of rickets. Cod-liver oil was introduced as a specific for rickets by the Frenchman Bretonneau. Trousseau and other physicians had convinced themselves of its effectiveness by clinical observation. By means of a histological test—the so-called lime test—McCollum, Simmonds, Shipley, and Park showed that cod-liver oil caused a remarkable deposition of lime salts in the cartilage of the rachitic rat close to its junction with the metaphysis. Howland and Park demonstrated also, by means of the x rays, the

\* Read at the Association Internationale de Thalassothérapie, at Arcachon, April 27th.

deposition of lime salts in the bones of rachitic children following administration of cod-liver oil. The specific action of cod-liver oil in curing and preventing human rickets has been established by many observers, more particularly by Chick and her collaborators in an extensive investigation in Vienna.

Although Mellanby was inclined to believe that the antirachitic principle of cod-liver oil was fat-soluble A, other observers began to doubt it. Findlay, using butter-fat, claimed that though it was rich in vitamin A yet it was poor as an antirachitic agent. Sherman and Pappenheimer first showed clearly that a diet deficient in vitamin A only would not produce rickets. This was confirmed by other investigators.

McCollum, Shipley, Simmonds, and Park compared the action of butter-fat and cod-liver oil, and came to the conclusion that the latter contained in abundance a substance that was antirachitic but which had no specific action on growth or the prevention of keratomalacia. McCollum, Simmonds, Becker, and Shipley proved that the antirachitic substance was distinct from fat-soluble A vitamin. Hopkins has shown that fat-soluble A vitamin is destroyed by combined heat and oxidation. McCollum and his co-workers treated cod-liver oil in this way until, as shown by tests on animals, it had lost its power to promote growth; this oil was found, nevertheless, to be potent as an antirachitic agent. This conclusive experiment settled once and for all the non-identity of vitamin A and the unknown antirachitic agent.

#### RADIANT ENERGY.

In 1919 the German physician Hulschinsky reported that he had cured cases of rickets in children by radiating them with the light from a quartz mercury vapour lamp. The action was not local, radiation of one limb healing the rickets of both limbs. This important observation was confirmed by many workers.

The quartz mercury vapour lamp emits rays rich in the ultra-violet region, and it was proved that the active rays were these short invisible ones. Window glass cuts off these rays, and Hulschinsky found that he could not cure rickets if the light of his mercury vapour lamp was filtered through glass. The active rays were the ultra-violet ones. Hess and his co-workers extended these observations and showed that ultra-violet light would cure and prevent rickets in rats. They also proved that other sources of ultra light—the carbon arc and cadmium spark—were active against rickets. By means of selective filters they were able to cut off different portions of the spectrum, and arrived at the conclusion that the active rays were those having a wave-length of 300  $\mu$  or shorter.

Hess and his co-workers and McCollum and his also showed that the rays of the sun would prevent rickets in rats. The sun's rays, it may be mentioned, extend down to about 290  $\mu$  in the ultra-violet region. If the sunlight is filtered through glass then it does not protect against rickets. Miss Chick and her co-workers proved the protective power of sunlight on a large number of children in Vienna fed on rachitic diet. The experiments we describe confirm and amplify the fact that ultra-violet light is specific in protecting against experimental rickets in rats.

Radiant energy, it must be concluded, is as important a factor in the cure and prevention of rickets as the unknown substance present in cod-liver oil and other oils. The children in city tenements in Britain are made rickety by a diet insufficient in antirachitic substances and by over-clothing and confinement indoors. Exposure of children more or less nude to sunshine or are lamps would be of great benefit.

Iversen and Lenstrup and Howland and Kramer showed independently that the blood in cases of rickets is low in inorganic phosphorus. The inorganic phosphorus of normal children is about 5 mg. per cent.; in cases of rickets it may fall as low as 1 mg. per cent. In rickets complicated by tetany the calcium in the blood is below normal. These chemical changes in the blood are well established by a large number of investigators, and it can now be asserted that rickets is always associated with a

diminished content of calcium or inorganic phosphate or both in the blood. In rachitic children it is usually the inorganic phosphorus that is low.

Hess, examining the blood of children in New York, claims to have shown that there is a seasonal variation of inorganic blood phosphate; it falls during the winter, reaching its minimum in March, and rises again in the spring and summer till it is at its maximum in the late summer. This observation confirms in a striking way the opinion of Palm, expressed, as has already been mentioned, so many years ago, that rickets is due to insufficient sunlight.
